Lardacein (so-called amyloid or albuminoid substance). This is formed in the disease known as waxy degeneration, the cells of the liver, spleen, and other organs being replaced by this substance. It is coloured brownish-red by iodine, hence the name amyloid (Virchow). Kekulé and Schmidt showed that it was a proteid. It is insoluble, like coagulated proteid, and it has been usually stated that it is not dissolved by gastric juice. Kostiurina (C. C. 1887, 120) finds, however, that it is soluble in pepsin solution acidified with hydrochloric acid.

The vegetable proteids have the same general reactions, and may be divided into the same classes as the animal proteids. Their percentage composition is also approximately the same, but varies with individual members of the group, as is the case with the animal proteids. Leucine, tyrosine, asparagine, and other amides are found in plants, which may perhaps be stages in the formation of proteids from the union of inorganic nitrogen with certain non-nitrogenous compounds in the plant tissues (C. O. Müller, L. V. 1886, 326). Various observers have found in vegetable tissues a crystallisable proteid, often spoken of as an albumin, but which has since been shown to consist of a globulin (vitellin). These crystals were first observed by Hartig (Botun. Zeitung, 1885, 881). Maschke obtained crystals from Para nuts by extracting them with water at 50°; the crystals formed on evaporating this extract at the same temperature (J. pr. 74, 436). Similar crystals have been obtained by Schmiedeberg (H. 1, 205), by Drechsel (J. pr. [2] 19, 331), Ritthausen (J. pr. 131, 481). G. Grübler obtained octahedral crystals from pumpkin seeds and castor-oil seeds by cooling to 7° a sodium chloride extract of the seeds made at 70° (J. pr. 131, 105). The aleurone grains of plants have been investigated by S. H. Vines (Pr. 30, 387; 31, 62); in the peony, castor-oil plant, blue lupin, and many other plants. Vines found that the grains are either wholly or partially composed of proteids, and classifies them according to whether (1) they are soluble in water, in which case they consist of vegetable peptone or hemi-albumose, (2) soluble in 10 p.c. sodium chloride solution, and (8) partially soluble in 10 p.c. sodium chloride

solution. In the two latter cases globulins and albumins are also present. For recent work on crystallised vegetable proteids see Osborne, Am. 14, No. 8.

CLASS I., VEGETABLE ALBUMINS.—In addition to the crystalline body just described, the position of which in our classification is properly in the next group, there are in vegetable juices true albumins. These have been prepared and analysed from rye by Jones (A. 40, 66), from wheat flour by Dumas and Cahours (A. Ch. [3] vi), by Boussingault (ibid. [2] 63, 225), from potatoes by Rüling (A. 58, 306), in the latex of several caoutchouc-yielding plants by J. R. Green (Pr. 40, 28), and in papaw juice by Martin (J. Physiol. 6, 336). Such albumins are coagulated by heat at about 70°, and are not precipitated by saturation with sodium chloride, magnesium sulphate, nor by acetic acid. The myrosin of mustard seeds also resembles vegetable albumin, and myco-protein from yeast and bacteria is also stated to be an albumin (Schaffler, J. pr. 131, 302).

CLASS II., VEGETABLE GLOBULING .-- These were first described by Vines (l.c.), and have since been classified by Martin (Proc. Physiol. Soc. 1887, 8), who has found them in the flour of wheat, rye, and barley, in papaw juice, and in the seeds of Abrus precatorius (jequirity). He divides them into two classes: vegetable myosine and vegetable paraglobulins. The myosins coagulate at 55°-60°, are precipitated by dialysing the salt away from their solutions; but this precipitate is no longer a globulin, being insoluble in saline solutions. It has the properties of an albuminate, i.e. soluble in weak acid or alkali and precipitated by neutralisation. similar transformation occurs when a solution of the myosin, especially a dilute solution, is placed in an incubator at 35°-40° for twelve to eighteen hours. The vegetable paraglobulins coagulate at 70°-75°C., and are not transformed into albuminates, either by dialysis or by a long exposure to a temperature of 35°-40°. This classification does not include plant vitellin (phytovitellin), the crystalline form of which has been already alluded to. The crystals are membraneless, doubly refracting, and the proteid of which they consist has all the reactions of vitellin prepared from yolk of egg. This vitellin was found to be free from nuclein and lecithin, and may be regarded as the purest globulin yet known. Elementary analysis gave C 52.43, H 7·12, N 18·1, S 0·55 p.c. (For further analyses of vegetable proteids see Barbière, J. pr. 126, 114.)

CLASS III., VEGETABLE ALBUMINATES.—Legumin and conglutin. Legumin, or vegetable casein, was discovered by Einhof in 1805, and called by him végéto-animale (N. allgem. J. D. Ch. v.; A. Gehlen, vi. 126, 548), in peas, beans, and lentils. Proust, H. Vogel, Boullay, Braconnot, and Liebig considered it to be identical with the casein of milk. Dumas and Cahours found that it contained less carbon and more nitrogen than casein (Gerhardt, Traite, 4, 491). The composition and properties of this proteid have been more recently studied by Ritthausen. He prepared it by extracting pulverised peas, beans, lettile, and vetches with dilute alkali, precipitating the strained liquid

with acetic acid, washing the precipitate with alcohol on a filter, and finally drying over sulphuric acid. It dissolves both in cold and boiling water; on analysis the following percentages were obtained: From peas, lentils, vetches, and field beans—C 51:48; H 7:02; N 16:77; O 24:32; S 0:40. From garden beans—O 51:48; H 6:92; N 41:71; O 26:35; S 0:45. Treated with sulphuric acid it yields leucine, tyrosine, glutamic, and aspartic acids. The legumin of almonds and lupines, called by Ritthausen conglutin, is richer in nitrogen, more glutinous, and more soluble in acetic acid (Ritthausen, J. pr. 103; 65, 78, 193, 273; [2] 26, several papers; Z. [2] iv. 528, 541; vi. 126; Gm. xviii. 427, 437). Legumin differing slightly in properties and composition has been prepared from many other sources.

The section of the property of

In spite, however, of the vast amount of work which has been done on this subject, and which is only briefly alluded to in the foregoing paragraph, the existence of this substance is now pretty generally denied. Fresh seeds or vegetable tissues and juices contain no proteids of the casein or albuminate group, and all the substances hitherto designated plant casein are artificial products produced by the alkali used to extract them from the various globulins and albumins which exist there normally (Hoppe-Seyler, Physiol. Chemie, Theil i. 75). Although Ritthausen defends his views (C. C. 1877, 567, 586) on the ground chiefly of the concordance of numerous elementary analyses, the recent work of Vines, Green, and Martin confirms Hoppe-Seyler's statement. For proteids of oats see Osborne, Am. 13, 327, 385; 14, 212; of maize, Osborne a. Chittenden, ibid. 13, 453, 529; 14, 20; of flax, Osborne, ibid. 14, No. 8.

CLASS IV .- VEGETABLE PROTEOSES. - These were first described by Vines (l.c.) in alcurone grains, and spoken of as hemi albumose by him. They were previously regarded as peptones. Martin (J. Physiol. 6, 336) has given the name phytalbumose to these substances. In papaw juice he found two phytalbumoses: a - phytalbumose, with which the ferment papain is associated; this resembles the proto-albumose of Kühne a. Chittenden, but differs from it in the fact that copper sulphate and saturation with sodium chloride do not precipitate it; \$-phytalbumose, which resembles hetero albumose, except that it is not precipitated by dialysing out the salts from its solutions, nor by copper sulphate, nor by mercuric chloride. Green (Pr. 40, 28) has described an albumose in latex; and Martin has found another albumose-insoluble phytalbumose-in wheaten flour (Brit. Med. Jour. 1886, 2, 104; see also under GLUTEN).

CLASS V. — VEGETABLE PEPTONES. — True peptone does not apparently exist as such in vegetable tissue; as the result of peptic or panoreatic digestion, however, peptones are formed with intermediate products (proteoses), as in the case of animal proteids. Some, moreover, are further acted on yielding leucine and tyrosine. It is interesting to notice that in the digestion of the proteids of papaw juice by papaïn, a proteolytic ferment present in that juice, no true peptones, but only phytalbumoses, are formed. Papain, however, which acts like trypsin best in

an alkaline medium, forms true poptones with animal proteids (Martin, J. Physiol. 5, 213; 6, 336). For ferments in pineapple juice see Chittenden, Trans. Connecticut Acad. 8, 1. It appears probable that such ferments are widespread in the vegetable kingdom to convert the proteid of the cotyledons into peptone-like substances, and so render it available for food in the growing plant.

CLASS VI.—INSOLUBLE VEGETABLE PROTRIDS. Gluten. This is the most important of the vegetable proteids which falls under this head. When wheat flour is made into a paste its stickiness is due to the presence of gluten, which can be obtained free from starch by washing the paste with water; this is most conveniently done by kneading the paste in a muslin bag under running water. Gluten is tenacious, almost tasteless, of a light brownish-grey colour; on being burnt it emits the smell of burnt horn. and on destructive distillation yields the same products as animal proteids. It dissolves in strong acids and alkalis; it also dissolves, but very slowly, in 0.2 p.c. hydrochloric acid (Bouchardat, C. R. 14, 962). Gluten has been stated to possess amylolytic powers, converting starch first into dextrin and then into dextrose. Taddei (Giornale fisica di Brugnatelli, 12, 360) first showed that gluten consists of two substances—one soluble, the other insoluble in alcohol. Ritthausen called the part insoluble in alcohol vegetable fibrin, and the part soluble in alcohol, and to which the stickiness of the gluten is due, he subdivided into two substances, mucedin or vegetable mucin, and glutin, gliadin or vegetable gelatin. These are extracted with boiling alcohol of 70-80 p.c. This extract becomes turbid on cooling, and after half the alcohol has been distilled off mucedin is deposited in flocculi. It may be purified by redissolving it in hot alcohol, and re-precipitating by cooling. The gliadin remains in solution in cold alcohol. Mucedin is soluble in cold dilute acetic acid, but when precipitated from this solution by ammonia, or left in contact with or boiled with water or dilute alcohol, it is converted into an insoluble substance like fibrin. Gliadin forms a solution in alcohol which resembles varnish; on evaporating the alcohol it is obtained in a form resembling animal gelatin. It is more soluble in hot than cold water, and is precipitated by tannic acid, basic lead acetate, and mercuric chloride. The analyses of crude gluten, and of glutin, give approximately the same percentage composition as other proteids (Ritthausen, J. pr. 74, 193, 384). Gunsberg (J. pr. 85, 213) regards mucedin as

Gunsberg (J. pr. 85, 213) regards mucedin as consisting simply of fragments of suspended fibrin; he states that gliadin is also not a distinct proximate principle, for cold water extracts from it a brown substance containing nitrogen and sulphur, and the residue has nearly the same composition as animal gelatin. Martin (Brit. Med. Jour. 1886, ?, 104) has shown that gluten does not exist in flour as such, but is formed by the action of water (perhaps also by a ferment action) on the proteids pre-existent in the flour. The doctrine of a ferment action is supported by the fact that washing flour with water at a low temperature (2°C.) does not lead to the formation of gluten. Johannsen (Ann. Agronom. 14,

420) has advanced evidence against the ferment theory. Gluten is insoluble in cold water, and in 10 to 15 p.c. sodium chloride solution. It dissolves partially in alcohol and in boiling water. Both these extracts contain the same substance, which is an albumose (insoluble phytalbumose), and it corresponds to Ritthausen's mucedin and gliadin. The insoluble residue, which is not sticky, may still be called gluten fibrin, and it is soluble in 0.2 per cent. hydrochloric acid. The flour itself contains two proteids: (1) A myosin coagulating between 55° and 60°, precipitated by sodium chloride and magnesium sulphate; and (2) a soluble phytalbumose. Both can be extracted from flour by 10–15 p.c. sodium chloride solution. They are considered to be the precursors of gluten, according to the following scheme:

Ginten = { Ginten-fibrin—precursor: myosin Insoluble albumose precursor: soluble albumose precursor: soluble albumose the more wheaten flour has been extracted with a 10 or 16 p.c. sodium chloride solution the less is the yield of gluten when it is subsequently treated with water.

The proportion of gluten in wheat flour varies considerably according to climate, soil, temperature, &c.; the best flour containing 10-11 p.c., inferior kinds 8-9 p.c. In the moist state gluten weighs about three times as much as when dry. The flours of barley, ryc, and oats contain only a trace of gliadin, or albumose, as it may now be regarded; hence these flours, containing mostly gluten-fibrin or its precursor, cannot be made into such a sticky paste as can be made with wheat flour. Gliadin also does not exist in leguminous seeds; it is said to be present in the juice of the grape and other fruits, and is held in solution there by tartario or other vegetable acids.

APPENDIX A.—Proteids in urine. Normal urine contains no proteid. The chief facts concerning proteids in morbid urine are treated fully in medical works (MacMunn's Clin. Chem. of Urine, Halliburton's Chem. Physiol.), but may be here briefly summarised as follows:

When urine contains blood (which may be detected by the microscope or spectroscope) or pus (which may be also detected microscopically), it of necessity contains a certain amount of proteid derived from these contaminations. In paroxysmal hemoglobinuris, the urine may contain hemoglobin or methemoglobin independently of the presence of blood corpuscles. In the various forms of Bright's disease, the unhealthy kidney allows the proteids of the blood to diffuse into the urine, the most common and abundant being serum albumin. Serum globulin is usually also present, and is recognised by the fact that saturation with magnesium sulphate in the neutralised urine precipitates it (A. Ott, C. C. 1886, 540). A crystalline globulin was found in urine by Paton, Lab. Rep. R. Coll. Phys. Edin. 4, 47.

Clinical observers do not as a rule attempt to distinguish, however, between the various forms of proteid that occur in urine, but speak of them all under the name of albumin. The most commonly applied tests for its detection are:—(1) To boil the upper part of a test tube full of urine; any cloudiness produced is then seen in contrast to the clear urine below. If any precipitate occurs it is insoluble in acetic acid, so distin-

guishing it from phosphates. If the urine is neutral or alkaline it is necessary always to acidify with acetic acid either before or after boiling, in order to obtain a precipitate. The clinical method of estimating the proteid quantitatively has been already described. (2) Nitric acid causes a precipitate in the cold. If urine contains but little proteid, it may be detected by pouring the urine on to the surface of some nitric acid in a narrow test tube, the ring of precipitate at the junction of the two liquids is then clearly seen (Heller). The difficulty of carrying nitric acid about has led to the adoption more recently of methods in which test papers saturated with various reagents, picric acid, potassio-mercuric iodide, &c., are added to the urine. A committee of the Clinical Society have recently presented a report in which the relative advantages of various methods of detecting albumin in urine are discussed (Clin. Soc. Trans. 19, 339). They have investigated Dr. Oliver's test papers just mentioned; Dr. Pavy's pellets of citric acid and potassium ferrocyanide; Dr. Johnson's picric acid solution; Sir W. Roberts's acid brine test; acetic acid and boiling nitric acid; and a solution of potassio-mercuric iodide with citric acid. The last named is the most delicate reagent in the list; the test papers and pellets are not so delicate but are more convenient; the pieric acid test has the advantage of being also applicable for recognising (after the addition of potash) sugar as well as albumin.

Besides albumin and globulin in urine, other proteids may sometimes occur; viz. (1) egg albumin—this occurs after a very large ingestion of eggs as food; (2) Bence-Jones albumin, so called after its first observer, has been shown to be a form of hemi-albumose—it occurs in cases of osteomalacia; (3) peptones or deutero-albumose occurs in many suppurative diseases, and doubtless originates from the disintegration of pus cells; (4) casein has been stated to occur in chylous urine, but there are considerable doubts as to the accuracy of this statement; (5) mucin occurs not only in suspension in the mucus from the urinary tract, but it appears to be occasionally present dissolved in the urine—it is precipitable therefrom by acetic acid. It is probably not true mucu, but a nucleo-albumin.

APPENDIX B .- Proteids as poisons. For effects on blood pressure, &c., of albumoses and pentones, v. Pollitzer, J. Physiol. 7, 283. The poison of venomous snakes has also been shown to depend on the proteids contained therein (Weir Mitchell), and not to any alkaloid, ptomaine, or cobric acid (W. Blyth, An. 1, 204) Wolfenden has separated a globulin, albumin, syntonin, and albumose from the venom of the cobra and daboia; for the action of these v. J. Physiol. 7, 827; see also Kanthack, *ibid.* 13, 272. The poisonous principle abrin of Abrus or Jequirity is also proteid (Martin, *Pr.* 42, 331). The subject of proteid poisons has recently risen into prominence, as it is found that the micro-organisms of many diseases produce these toxalbumoses. Koch's tuberculin owes its activity to similar substances. The poisons produced in anthrax, diphtheria, &c., are also proteid in nature. For references see Halliburton's Chem. Physiol. German translation; Martin, Brit. Med. Journal, March and April 1892. On the other hand

PROTEIDS. 889

sertain proteids (globulins or nucleo-albumins) are protective and destroy micro-organisms. They are termed alexines by Daremberg, Buchner, and Hankin. For Hankin's most recent paper, see *Centr. Bacteriol.* 12, Nos. 22 and 23.

APPENDIX C.—Albuminoids. The term 'albuminoid' is still used by some synonymously with proteid; it will be here restricted to a number of substances which resemble proteids in many points, but which differ from them in others.

Collagen. This is the substance of which the white fibres of connective tissue are composed, and which by the action of boiling water is converted into gelatin. Collagen is prepared from tendons by Rollett's process as follows: the finely-divided tissue is soaked in water to remove proteids, and then for some days in lime water to dissolve the mucin-holding cementing substance between the fibres. The insoluble matter is washed first with water, then with weak acctic and then again with water. The residue consists of collagen, mixed, however, with small quantities of elastin and nuclein. With very dilute acids or alkalis collagen swells and becomes transparent.

The organic material which composes onethird of the substance of bone consists mainly of a substance identical with collagen, and which has been termed ossein by some writers. The organic basis of dentine (but not of the enamel of teeth) is also collagenous.

Gelatin. When the white fibres are subjected to the action of boiling water, or of water heated under pressure, as in a Papin's digester, or to the long-continued action of dilute acids at the ordinary temperature, they dissolve, and the solution contains a substance called gelatin. Gelatin may be similarly prepared from bones. Isinglass is gelatin prepared from the swimming bladder of the sturgeon; an inferior kind is made from fish bones. Glue is the crude product obtained by boiling down hides, hones, &c. (v. Ure, Dictionary of Arts, &c., [2] 324, 376). Pure gelatin is prepared from commercial gelatin by soaking the latter in distilled water for some days to remove salts; it is then dissolved in hot distilled water, and filtered while hot into 90 p.c. alcohol. The gelatin separates in the form of white thready masses, which can be subsequently dried. Thus prepared it contains only 0.6 p.c. of ash.

Gelatin is insoluble in cold, but soluble in hot water; on cooling the hot watery solution it sets into a jelly (gelatinises); this property is possessed by solutions as weak as I p.c., it is lost by prolonged boiling, or instantly by heating to 140° in sealed tubes. Gelatin is insoluble in alcohol, ether, and chloroform. Aqueous solutions are powerfully hevorotatory, the rotatory power being influenced by the temperature and reaction of solution; at 30° [a] p = -130 (Hoppe-Seyler). Gelatin is not precipitated by acetic acid nor by a solution of lead acetate; it may be thus distinguished from chondrin. It is not precipitated by acetic acid and potassium ferrocyanide, nor by the majority of metallic salts which precipitate proteids. Tannic acid even in very dilute solutions precipitates it; it is on the formation of the last-named precipitate that the conversion of hides into leather is brought about.

Schützenberger and Bourgeois ascribe to gelatin the formula $O_{18}H_{124}N_{24}O_{29}$. Hofmeister (H. 2, 315) finds that by heating gelatin it loses water, and is converted into collagen, which he therefore considers an anhydride of gelatin; his formula for celatin is $C_{12}H_{11}N_{12}O_{22}$.

formula for gelatin is C_{10} . $H_{151}N_{31}O_{35}$.

By the action of boiling water, gelatin loses after 25 hours its power of gelatinising, and it is split up into two peptone-like bodies, semiglutin (sparingly soluble in 70-80 p.c. alcohol and precipitated by platinum tetrachloride) and hemicollin (soluble in 70-80 p.c. alcohol, not precipitated by platinum tetrachloride). Similar substances are formed by the action of the peptic or pancreatic ferment, but ultimately true gelatin peptones (not precipitable by saturation with ammonium sulphate), leucine, glycocine, and volatile fatty acids are formed. (The foregoing account of gelatin is very largely taken from Gamgee's Physiol. Chem., p. 252.) Many bacteria liquefy gelatine. On digestion of gelatin see Chittenden, J. Physiol. 12, 23, 34. The most recent work on the decomposition products of gelatin has been done by Schützenberger. On heating gelatin at 200° with barium hydroxide, one-fifth of the total nitrogen is converted into ammonia; carbonic and oxalic acids are also formed, these products being in the ratio of the products of decomposition of urea and oxamide. The other products are amidoacids of the acetic series, the most important being glycocine, alanine, amido-butyric acid and leucine, and acids of an homologous series $C_nH_{2n}N_2O_{2n}$ the value of n varying from 8 to 10. These latter acids are difficult to isolate; at 100°-120° they are converted into anhydrides; they do not yield derivatives with acetic anhydride, but with ethyl iodide in the presence of an alkali they yield di-ethyl derivatives. general results lead to the conclusion that gelatin is formed by the combination with elimination of water of 1 mol. urea or oxamide with 2 groups $C_nH_{2n}N_iO_i$ and 4 groups $C_nH_{2n}N_iO_i$ and 4 groups $C_nH_{2n}N_iO_2$, n being 2, 3, 4, or 6, with a mean value of 3.5 (v. Schützenberger a. Bourgeois, C. R. 82, 262; Schützenberger, C. R. 102, 1296) Both gelatin and albumin yield on treatment with alcoholic hydrochloric acid a diazo-compound C. H. N.O. (Buchner a. Curtius, B. 19, 850)

The question of the part played by gelatin, which is an easily-digestible substance in nutrition, is very important practically, jellies especially being given to invalids. The question was first investigated by J. Etzinger (N. R. P. 23, 535), and subsequently by Voit (Z. B. 8, 297). Voit's chief result showed that gelatin will not entirely replace proteids, but that animals rapidly waste which are fed on it alone, but, in conjunction with a certain small amount of proteid, it is capable of maintaining nitrogenous equilibrium as well as if the only nitrogenous food taken was proteid in nature. These results have been since very generally confirmed (v. S. Pollitzer, Pf. 37, 301). Voit distinguishes between circulating and organic albumin; gelatin can never yield the latter, but it may replace the former in so far as it prevents the conversion of organic into circulating albumin. Gelatin also diminishes the waste of fat in the body.

Mucin. This body forms the chief constituent of the ground substance of connective tissue, the other organic constituent being a globulin very like serum globulin. Mucin is especially abundant in the 'jelly like' tissue of the umbilical cord, and in the vitreous humour. The cement-substance of epithelia behaves similarly to microscopic reagents (especially silver nitrate, by which it is stained brown owing to a deposit of metallic silver), and is probably of the same chemical nature as the ground substance of connective tissue; both are soluble in alkalis. Mucin forms the chief constituent of mucus, and gives the sliminess to the secretion of mucous membranes. In mucus it is suspended in an alkaline exudation from the blood and mixed with the debris of epithelium cells, and a lew white blood corpuscles. The mucin itself is here formed by the protoplasm of certain cells of the epithelium becoming altered, so that it becomes swollen and brightly refracting; the globule of mucin so formed is discharged, leaving a so-called goblet cell. In mucous glands, such as the submaxillary salivary gland, a very similar replacement of protoplasm by mucin (or mucigen, as it is called when inside the secreting cells) takes place. Mucin is also largely contained in the surface secretion of several invertebrate animals, e.g. the snail. Mucin is contained in submaxillary saliva; the metalbumin and paralbumin (q, v) of ovarian cysts is a very similar substance. The substance which confers sliminess to the bile and the synovial fluid. formerly considered to be mucin, has been shown to consist of a nucleo-albumin (q. v.).

The methods of preparation of mucin from its various sources differ; from tendon (v. Rollett, Sitz. W. 30, 308; Löbisch, H. 10, 40); from submaxillary gland (Obolensky, Pf. 4, 336; Hammarsten, H. 12, 163); from bile (Gautier, Chimie Appliquée à la Médecine, 2, 126; Paijkull, H. 12, 196). Eichwald, Hammarsten, and others have prepared it from snails (Pf. 36, 373), and Giacosa (H. 7, 40) from the membranes of frog's eggs. These methods depend upon the fact that mucin is soluble in weak alkalis, e.g. lime water or dilute baryta water, and can be precipitated from this solution by acetic acid, in excess of which it is not soluble. Hammarsten finds, however, that submaxillary mucin is easily decomposed by lime water and similar weak alkaline fluids; he, therefore, uses water to extract the mucin. Hammarsten has shown that considerable differences exist in mucin according to its origin; this was previously suspected from the divergencies in elementary composition. Tendon mucin (C, 48.3; H, 6.44; N, 11.75; S, 0.81 p.c., Loebisch) and submaxillary mucin (C, 48.84; H, 6.8; N, 12.32; S, 0.8, Hammarsten) are very much alike in elementary composition, but differ in their reactions; e.g. tendon mucin is not easily decomposed by weak alkalis, nor is it so easily soluble in weak hydrochloric acid as submaxillary mucin. These forms of mucin differ still more from those obtained from Helix pomatia; Hammarsten, indeed, has shown that two distinct varieties of mucin, from the foot and mantle respectively, can be obtained from

Mucin gives the xanthoproteic, Millon's, and the Adamkiecwicz reactions: it is precipitated.

but not rendered insoluble, by saturation with sodium chloride or magnesium sulphate, and by alcohol. It is precipitated by acetate of lead, but by no other metallic salt (except the submaxillary mucin, which is precipitated by several), it is not precipitated by tannic acid nor by boiling; acetic acid gives a characteristic stringy precipitate. Mucin yields, when boiled with strong sulphuric acid, leucine and tyrosine, and when boiled with caustic soda pyrocatechin (Obolensky). When boiled with dilute sulphuric acid for a few hours, mucin yields a reducing sugar, but one which is not capable of the alcoholic fermentation, and albumin is also formed. Landwehr regards mucin as a compound of a proteid and a non-reducing carbohydrate (C.H.,O.) which has most of the properties of plant gum; he calls it animal gum (Pf. 39, 193). At one time this carbohydrate was regarded as a variety of glycogen which gave no colour with iodine (achrooglycogen).

Met-albumin and paralbumin. These two proteid-like substances are fairly constantly found in the fluids removed from ovarian cysts (Scherer), and occur occasionally in other cysts and in ascitic fluid also. Metalbumin is a form of mucin (pseudomucin); paralbumin differs from metalbumin by giving a precipitate when it is boiled; it is probably a mixture of pseudomucin with albumin, and can indeed be prepared by mixing these two substances. Both yield reducing sugars when boiled, and both contain animal gum (D. Hammarsten, Maly's Jahresb. 11, 11; Landwehr, H. 8, 114; Pf. 39, 193; Ocrum, Maly's Jahresb. 14, 459).

Ocrum, Maly's Jahrsb. 14, 459).

Nuclein. This is the name given to the substance which composes the nuclei of cells. It was prepared by Lauder Brunton from the red blood corpuscles of birds and snakes : the nuclei were freed from adhering stroma and homoglobin by repeated agitation with ether and water (Journ. of Anat. and Physiol. 2nd series, 3 91). Nuclein resembles mucin in its solubilities. Plosz found, however, that it contained phosphorus (Hoppe-Seyler, Med. Chem. Untersuchungen, Heft 4, 460), and considered it was identical with the nuclein which Miescher separated from the nuclei of white corpuscles (ibid.). Miescher separated the nuclein from the other constituents of the cells by subjecting them to artificial gastric digestion, nuclein, like mucin, being indigestible by pepsin. Miescher ascribes to it the formula C₂₂H₄₀N₂P₃O₂₂. Nuclein has also been separated from the brain (Jaksch, Pf. 13, 469) to the amount of 0.14 p.c. (Geoghegan, H. 1, 330), and from the liver; it is probably present in all parts where nucleated cells occur. Miescher has also described nuclein as occurring in the yolk of hens' eggs; it has also been described in milk. A. Kossel (H. 10, 248) has shown that the nuclein of volk and milk differ from that of cell nuclei in containing iron, and by not yielding guanine and hypoxanthine when decomposed at a high temperature by weak acids. Adenine C,H,N, is described by Kossel as being an intermediate product between cell nuclein and hypoxanthine. Nuclein is present in vegetable cells also, and adenine can also be obtained from this. It is present in yeast (Hoppe-Seyler) and mildew; in tea leaves (Kossel), in poppy, earth nut, rape and cotton

941

cake; also in palm nut, but the proportion P:N is different in the nuclein prepared from this source (Klingenberg a. A. Stutzer, B. C. 1883, 204). Miescher's formula for nuclein must, indeed, be received with caution; there are either several varieties of nuclein-for elementary analyses show great discrepancies—or else, as Worm Müller (Pf. 8, 190) supposes, it is no definite chemical individual, but the different nucleins are mixtures of an organic phosphorus compound with varying quantities of proteids. Recent work on nuclein has shown that this phosphorus compound is nucleic acid (Altmann, Arch. f. Anat. u. Phys. 1888. 524). For artificial nuclein made by adding phosphoric acid to albumin see Liebermann, B. 21, 598; Pohl, H. 13, 292; Malfatti, B. d. Naturwiss. Med. Ver. Innsbruck, 1891-2; Kossel, Verh. physiol. Ges. Berlin, Oct. 21, 1892. See also numerous papers by Kossel, Krüger, and others on adenine and nuclein bases in last few volumes of H. For iron compounds of nuclein see Bunge's Physiol. Chem. This haematogen is probably the normal iron-containing food. The chromatin and plastin of histologists are respectively phosphorus-rich and phosphorus-poor nucleins. For iron in the nucleus see Macallum, P. 49, 488.

Nucleo-proteids. Nucleo-albumin. E. Merck (D. P. J. 261, 316) calls nucleo-proteids substances which, when boiled with water under pressure or treated with acids, alkalis, or ferments, are resolved into nuclein and albumin; for instance, vitellin and casein (v. also Lubavin. Hoppe-Seyler, Med. Chem. Unters. p. 447), Hammarstengives the name nucleo-albumin to a class of proteid-like bodies which are very like globulins, being precipitated from their solutions by saturation with sodium chloride or magnesium sulphate; they are also precipitated by acetic acid, but, unlike mucin, are soluble in excess. On gastric digestion of a clear solution, an insoluble phosphorus-containing substance, like nuclein, is formed. Many nucleo-albumins have the physical characters of mucin, and the sliminess of bile and synovia is due to such bodies (Hammarsten, H. 12, 173, on synovia; Maly's Jahrsber. 12, 1882, on bile-mucin; Paijkull, H. 12, 196). The chief proteid constituent of all protoplasm is nucleo-albumin (Halliburton's Goulstonian Lectures, Brit. Med. Journ., March 1893). Wooldridge's tissue fibrinogens are also nucleo-albumins (for ref. see above lectures).

Chondrin. This is the substance obtained from cartilage by boiling; the mother substance of chondrin in the matrix of the cartilage is termed chondrigen. Hot aqueous solutions of chondrin gelatinise on cooling like those of gelatin. Aqueous solutions are precipitated by the same reagents that precipitate solutions of gelatin and of mucin. It is strongly lawor otatory; its rotatory power in solutions of different strengths has been studied by de Bary (Med. Chem. Unters. i. 71). Very great discrepancies exist between the results of various analyses (see table comparing analyses by Mulder, Fischer a. Bödecker, Schützenberger a. Bourgeois, and v. Mehring in Gamgee's Physiol. Chem. p. 270), hence considerable doubts have been entertained of its being a chemical individual. It gives the reactions both of mucin and gelatin; on being boiled with dilute acids it

yields a lævogyrate reducing augar, called by de Bary chondriglucose (v. also Fischer a. Bödecker, A. 117, 111), but is now regarded as identical with that obtained from mucin, Landwehr considering that animal gum is contained in chondrin as in mucin (Pf. 39, 204, 40). Morochowitz was the first to arrive at the conclusion that chondrin is a mixture of gelatin and mucin (Verhandl, d. naturhist, med. Vereins zu Heidelberg, 1, Heft 5); mucin can be extracted from it with lime or baryta water, and pure gelatin is left behind. On this assumption chondrigen collagen + mucin. It must, however, be mentioned, in opposition to this view, that Hoppe-Seyler (J. pr. 56, 129) and Otto (Z. [2] 4, 628) state that on treating chondrin with dilute sulphuric acid it yields leucine, but no tyrosine or glycosine. The most recent work on chondrin shows that it is chondroitic acid rather than mucin which is present (C. T. Mörner, H. 12, 396; Skand, Arch. Physiol. 1, 210; Krukenberg. Z.B. 20, 307; Schmiedeberg, Arch. exp. Path. u. Pharm. 1891, 355).

Elastin. This substance is the very insoluble material of which the clastic fibres of connective tissue are composed. It may be prepared from the ligamentum nuchee by boiling it with ether and alcohol to remove fatty matters, then for 36 hours with water to remove the collagen. The residue is boiled with strong acetic acid, and afterwards with concentrated caustic soda till the fibres begin to swell; it is then treated with weak acetic acid, water, and lastly for 24 hours with hydrochloric acid. The acid is removed by washing with water, and the residue has still all the characters of fresh clastic tissue, and has the following percentage composition: C, 55-45; II, 7-41; N, 16-19; O. 20-80 (Müller, Zeit, f. Nat. Med. 3, 10, Heft 2). For recent analyses see Chittenden, Z. B. 25, 368.

Elastin is not soluble in any liquid which does not decompose it. It is soluble in boiling concentrated caustic potash, in concentrated nitric and sulphuric acids. It is digestible by both pepsin and trypsin; the former ferment being the more active (A. Ewald a. W. Kühne, Die Verdanung als histol. Methode). Peptones are ultimately formed; there are also intermediate bodies of the nature of albumoses (Horbaczewski, C. C. 1885, 843). Elastin when treated with sulphuric acid yields leucine but no tyrosine.

Keratin. This substance replaces the protoplasm in the cells of certain epidermal structures, viz. the superficial layer of the epidermis itself, nails, horns, hoofs, feathers, and the cuticle and fibrous substance of hairs. It is prepared by successively boiling the tissue with ether, alcohol, water, and dilute acids; the insoluble residue is keratin.

Subjected to the prolonged action of water under pressure at 150°-200° it yields a turbid solution. It is also dissolved by boiling with alkalis, and on the addition of acids to this solution sulphuretted hydrogen is given off, the sulphur in keratin, which varies considerably in amount, being very loosely combined. Horn swells in dilute acetic acid, dissolves in boiling glacial acetic acid, and in nitric acid; it yields aspartic acid, volatile fatty acids, leucine and tyrosine when boiled with dilute subhuric acid.

when burnt it gives off a characteristic smell. The following are the chief analyses that have been made (Hoppe-Seyler, *Physiol. Chem.*, Th. 1, p. 90):—

_	Hair	Nails	Horn	Hoof
	(r. Laer)	(Mulder)	(Tilanus)	(Mulder)
O	50·60	51·00	51·03	51·41
H	6·36	6·94	6·80	6·96
N	17·14	17·51	16·24	17·46
O	20·85	21·75	22·51	19·49
S	5·00	2·80	3·42	4·23

Neurokeratin. This is a substance which forms an irregular framework in the medullary sheath of nerve fibres, which resembles keratin in its general behaviour, but differs from it in being less easily soluble in boiling solutions of caustic potash (Ewald a. Kühne, Verhandl. d. naturnist. med. Vereins zu Heidelberg, 'vol. i. Heft 5; Kühne a. Chittenden, Z. B. 26, 291). This substance is interesting, as both the epidermis and the nervous system are derived from the epiblast of the embryo.

Chitin. This substance forms the chief constituent of the skeletal octodermal tissues of invertebrate animals, especially arthropoda. list of situations in which it has been described is given in Gamgee's Physiol. Chem. p. 299; to these must be added the pen of cuttlefishes (Krukenberg), the cartilages and other mesodermal tissues of sepia and the king-crab (Halliburton, Pr. 88, 75). In crustacea it is often impregnated with calcareous matter, and in the odontophore of molluses with silica. It is prepared from the wing-cases or shells by boiling them with caustic soda. The chitin remains insoluble. It may be dissolved in cold concentrated hydrochloric acid, and the solution precipitated by the addition of water. It is colourless, amorphous, insoluble in water, alcohol, ether, acetic acid, dilute mineral acids, and solutions of the alkalis. It is dissolved by concentrated mineral soids. (On the solubilities of chitin v. Krukenberg, Z. B. 22, 480.)

The formula for chitin is C₁₃H₁₈N₂O₁₆ (Led-

The formula for chitin is C₁₃H_mN₂O₁₀ (Ledderhose, H. 2, 213; 4, 139). Berthelot (C. R. 47, 227) stated that it yields a fermentable sugar on boiling it with sulphuric acid; and Sandwick considered it to be an amine derivative of a carbohydrate with the formula N(C₁₂H_mO₁₀). Ledderhose showed, however, that the reducing substance is a nitrogenous body, glucosamine; and when chitin is heated with acids it takes up the elements of water, and yields glucosamine

and acetic acid,

 $2C_{19}H_{28}N_2O_{16} + 6H_1O = 4C_6H_1NO_5 + 2C_1H_1O_2$. Glucosamine is an amido- derivative of grape sugar $(C_6H_1O_4 - OH + NH_2 = C_4H_1NO_5)$; it forms salts, of which the hydrochloride is formed by boiling chitin with hydrochloric acid; this is a crystalline substance soluble in water, and in solution dextrorotatory $(a_D = +70^{\circ}6^{\circ})$. The pure base prepared by the action of barium hydrate on the sulphate of glucosamine crystallises from alcohol in the form of needles. It is not fermentable. (The foregoing account of elastin, keratin, and chitin is largely taken from Gamgee's *Physiol. Chem.*, which see for fuller details.)

Skeletins. This term is applied by Krukenberg (Z. B. 22, 241) to a number of nitrogenous but sulphur-free substances, including conchiolin, spongin, &c., found in the skeletal tissues of invertebrates; they are probably all like chitin amido-derivatives of carbohydrates. The substances are all very insoluble.

Conchiolin (C₂₀H₄₈N₃O₁₁) forms the organic basis of the shells of mussels and snails. On decomposition it yields leucine, perhaps glycocine, but no tyrosine nor reducing substance. It does not give the xanthoproteic, Millon's, nor the Adamkiewicz reactions. The cementing substance between the eggs of various mollusces, whose shells and egg capsules contain conchiolin, is coloured red by heating with Millon's reagent, and contains a body allied to keratin. Cornein (from corals) (C₂₀H₄₄N₃O₁₃) differs from conchiolin by giving a red colour with Millon's test.

Spongin, the organic basis of the common sponge, yields as decomposition products leucine and glycocine (Stüdeler), but no tyrosine. It does not give any of the colour reactions mentioned above; it also resembles conchiolin by yielding on digestion peptone-like substances which differ from true peptones and albumoses by not giving the three colour reactions just mentioned; they thus differ from keratin, which is not digestible.

Fibroin, the chief constituent of insects' cocoons and spiders' threads, behaves to all three tests like an ordinary proteid, and on decomposition yields leucine, glycocine, and tyrosine. Fibroin is soluble when heated in sealed tubes in glacial, acetic, and other organic acids (A. Ledow, Maly's Jahrsbericht, 13, 32). For silk see Weyl, B. 21, 1407, 1529.

Hyalins and Hyalogens. The term 'hyalin' is applied to the chief constituent of the walls of hydatid cysts. Krukenberg states (Z. B. 22, 261) that the substance is present in the cyst wall as hyalogen, an insoluble substance which by the action of alkalis is changed into hyalin, which is easily soluble in water. Hyalogen is also converted into hyalin by heating with water (under pressure) at 150°C. (For elementary composition v. Lücke, Virchou's Archiv, 19, 189). By heating with sulphuric acid hyalin yields a sugar, probably glucose, which is dextrorotatory and capable of the alcoholic fermentation, and in this hyalin resembles muoin.

Krukenberg has extended the terms hyalogen and hyalin to other similarly related bodies obtained from various sources. The edible bird's nest has properties very like those of mucin (v. J. R. Green, J. Physiol. 6, 40), and is the result of the activity of certain glands described by Bernstein (Journ. Ornithologie, 1859. 111) as being remarkably developed in the nest-building season. Krukenberg finds that it is chiefly composed of a hyalogen (neossine), which yields as its hyalin, neossidine. Chondrosine is a hyalogen, obtained from the sponge Chondrosia reniformis. The vitreous humour from the eyes of oxen and pigs was found to contain a hyalogen, whereas the cornea did not yield one, but was found to consist chiefly of collagen, and a proteid allied to myosin. Spirographin, which largely composes the skeletal tissues of the worm Spirographis is also a hyalogen, but differs from others by yielding when acted on by alkalis

not only a hyalin, spirographidin, but also pyrocatechin. The hyalogens are not acted on by gastric juice; some are, some are not attacked by trypsin. W. D. H.

PROTEÏN v. PROTEÏDS. PROTEOSES v. PROTEÏDS. PROTO-ALBUMOSE v. PROTEÏDS.

s. C₁H₄O₄ ... [199°] 12, PROTOCATECHUIC ACID C4H3(OH)2.CO2H[4:3:1]. Mol. w. 154. (Hlasiwetz); [194°] (Barth a. Schmidt, B. 12, 1265). S. 1.9 at 14°; 10 at 60° (Tiemann a. Nagai, B. 10, 211). Occurs in the fruit of Illicium religiosum (Eykman, R. T. C. 4, 47).

Formation. - 1. By potash-fusion from piperic acid (Strecker, A. 118, 280), catechin (Kraut, A. 128, 285), maclurin (Hlasiwetz a. Pfaundler, A. 127, 351), guaiac resin (Hlasiwetz a. Barth, A. 130, 346), kino (Stenhouse, C. J. 28, 6), cafferd acid (Hlasiwetz, A. 142, 219), cinchona-red (Bembold, A. 143, 273), asafætida (Hlasiwetz a. Barth, A. 138, 61), angelica-resin (Brünner, N. R. P. 24, 641), many other resins, the methyl- derivative of sulpho-p-oxy-benzoic acid (Malin, A. 152, 109), sulpho-m- and sulpho-p-oxy-benzoic acids (Barth, C. J. 24, 829), and iodo-p-oxy-benzoic aldehyde (Tiemann a. Herzfeld, B. 10, 213).—2. By heating piperonylic acid with HClAq at 150° (Fittig a. Remsen, A. 159, 129).—3. By the action of Br and water on quinic acid (Hesse, A. 112, 52; 122, 221; Fittig, A. 168, 111).-4. By heating pyrocatechin with water and ammonium carbonate at 140° (Miller, C. J. 41, 400).

Properties.-Tufts of monoclinic needles (containing aq), sol. water, alcohol, and ether, nearly insol. boiling benzene. FeCl, colours its aqueous solution bluish-green, the colour changing to red on addition of alkalis. FeSO, colours pp., sol. acetic acid. Crystallises with p-oxybenzoic acid as (C,H₂O₃)C,H₄O₃ 2aq, which yields PbC₁₄H₁₀O₂ 2aq (Hlasiwetz, A. 134, 276). Reduces aqueous AgNO, on heating or on adding NH, Aq. Does not reduce Fehling's solution.

Reactions.—1. Split up by dry distillation into CO₂ and pyrocatechin.—2. Soda-fusion gives 55 p.c. of the theoretical amount of pyrocatechin .- 3. Bromine in the cold forms bromoprotocatechuic acid. Br at 100° yields tetra-bromo-pyrocatechin.—4. N₂O₃ passed into the ethereal solution forms oxalic acid (16.5 p.c.), carboxy-tartronic acid (10 p.c.), di-nitro-di-oxy-quinone (5 p.c.), trinitrophenol (4 p.c.), (a)-dintiro-phenol [114°] (3°5 p.c.), and nitro-phenol end of the process and of the process and the quantity of tetra-oxy-anthraquinone (ruflopin) (Nölting, Bl. [2] 37, 395).—6. Heating with As,O, at,160° or exposing a solution in Na,CO,Aq to the air forms catellagic acid C14H1.O,? which resembles ellagic acid and forms an orange solution in nitric acid.

Salts.—BaA', 5aq.—Ba₁(C,H₁O₁)₂ (dried at 130°) (Barth, A. 142, 246).—CaA', 4aq.—CaA', 3aq.—Pb_A',O₂.—PbA', 2aq.
Acetyl derivative O₂H₂(O_AO₂, CO₂H. [158°]. Crystals (Herzig, M. 6, 872).

Methyl ether MeA'. [134·5°]. Needles.
Ethyl ether Eth'. [184° cor.]. Prisms (Matemato R. 11.190).

(Matemoto, B. 11, 129).

m-Methyl derivative C.H.(OH)(OMe).CO.H [4:3:1]. Vanillie acid. [207°]. S. 12 at 14°; 2·5 at 100°. Formation (Tiemann, B. 8, 509, 1123; 9, 52, 419; 10, 59, 202; 11, 122).-1. By exposing moist powdered vanillin to the air.—2. By oxidising coniferin with dilute KMnO₄.—3. From its acetyl derivative, which is got by the action of KMnO, on acetyl-eugenol, acetyl-ferulic acid, and acetyl-creosol.—4. Together with isovanillic acid by heating C.H. (OMe) CO.H with HClAq at 140°. Properties. Needles (from water), v. e. sol. alcohol, m. sol. ether. Has no smell. May be sublimed. Gives no colour with FeCl. Reactions.—1. Split up by HClAq (S.G. 1·1) at 150° into protocatechuic acid and MeI.—2. Potashfusion yields protocatechuic acid.—3. By heating with MeI (2 mols.) and KOH (2 mols.) it is converted into C.H. (OMe) .CO.Me. -4. Yields guaia. col on distillation with lime.—5. The Ca salt yields vanillin on distilling with calcium formate.

Methyl ether of the m-Methyl deriva-

tive MeA'. [63°]. (286°).

Ethyl ether of the m-Methyl derivative EtA'. [44°]. (292°).

Acetyl derivative of the m-Methyl derivative C,H₂(OAO)(OMe).CO₂H. [142°]. Needles (from dilute alcohol).

Benzoyl derivative of the m-Methyl

derivative. [178°] (Tiemann, B. 15, 2068).

p-Methyl derivative
C.H.(OMe)(OH).CO.H [4:3:1]. Isovanillic acid.
[250°]. S. 06 at 15°; '7 at 100°. Formed with Isovanillic acid. other products by heating protocatechuic acid with MeI and KOH at 150°. Got also by heating hemipic acid with HClAq (Matthiessen a. Foster, A. Suppl. 2, 378), and, together with vanillic acid, by digesting C_aH₁(OMe)₂CO₂H with dilute HClAq at 140° (Tiemann). The acetyl derivative in the contract of the con tive is got by oxidation of the acetyl derivative of isoferulic acid (hesperetic acid) by KMnO₄ (Tiemann a. Will, B. 14, 963), and likewise by exidation of the acetyl derivative of betelphenol C.H.₃(OMe)(OH).C.₃H.₃(4:3:1] (Bertram a. Gildemeister, J. pr. (2) 39, 349). Prisms, v. sol. alcohol and ether. May be sublimed. Its aqueous solution is not coloured by FeCl. Yields a nitro- derivative [173°] and an acetyl deriva-tive C.H. (OMe) (OAc).CO.H [207°].

Di-methyl derivative C.H.(OMe), CO.H.
Veratric acid. [174°] (T.); [181°] (G.). S. 05
at 14°; 6 at 100°. Occurs in small quantity in
sabadilla seeds (Merck, A. 29, 188). Formed by
heating at 140° protocatechnic acid (1 pt.) with
MeI (4 pts.) and KOH (1 pt.) dissolved in MeOH
(KSI) A. 150 241. MeI (4 pts.) and KOH (1 pt.) dissolved in MeOH (Kölle, A. 159, 241). Produced also by oxidation of C.H.Me(OMe). (Tiemann, B. 8, 1138), of methyl-eugenol (Graebe, A. 158, 282), of papaverine (Goldschmidt, M. 6, 378), and of dimethyl-eaffele acid (Tiemann a. Will, B. 14, 962). Formed also by seponifying its amide, which is made by the action of Cl.CONH, on C.H.(OMe), in CS, in the presence of AlCl. (Gattermann, A. 244, 71). Veratric acid is a product of the action of alcoholic soda on pseudaconitine, on veratrine (Wright a. Luff. pseudaconitine, on veratrine (Wright a. Luff. C. J. 33, 160, 353), and on hexa-methyl-quercetin (Herzig, M. 5, 83), and of fused potash on papaveraldine (Goldschmidt, M. 7, 493). Veratric acid is also got by the action of KOH on pseudo-opianic acid (W. H. Perkin, jun., C. J. 57, 1068).

Properties.—Slender needles (containing aq). From hot solutions (above 50°) it separates in anhydrous crystals. V. e. sol. alcohol and ether. FeCl, gives no colour. Distillation with lime forms C,H,(OMe)₂. Potash-fusion yields protocatechuic acid. HIAq at 160° forms MeI and protocatechuic acid. HClAq forms vanillic and also iso-vanillic acids.—Salts.—NaA' 2aq.— BaA'₂ 6aq. — AgA'. — Ethers. — MeA' [60°] (c. 800°).—EtA'. [44°]. (296°).

Di-ethyl derivative C,H,(OEt), CO,H. [166°]. Formed by saponifying its ether, which is made from protocatechuic acid, alcoholic potash, and EtI (Kölle, A. 159, 240). Got also by heating hexa-cthyl-querectin with alcoholic potash at 150° (Herzig, M. 5, 78). Needles (from alcohol).—KA' 'aq.—BaA', 2aq.—AgA'.—Ethyl ether EtA'. [57°]. Crystals.

Methyl-ethyl derivative C,H,(OMe)(OEt).CO,H [3:4:1]. [194°]. Formed by oxidation of ethyl-vanillin (Tiemann, B: 8, 1130), of ethyl-eugenol (Wassermann, A. 179, 379; Balbiano, G. 11, 416), and of di-ethyl-curcumin (Jackson a. Mencke, Am. 4, 90). Needles, almost insol. cold water. - BaA', 4aq: needles.

Methyl-propyl derivative C.H. (OMe) (OPr).CO.H [3:4:1]. Formed by oxidation of the propyl derivative of eugenol (Cahours, Bl. [2] 28, 314). Needles.

Methyl-carboxymethyl derivative O₆H₈(OMo)(O.CH_CO₂H).CO₂H [3:4:1]. f256°1. Formed from C,H,(OMe)(O.CH, CO,H).CHO by oxidation (Elkan, B. 19, 3056). Yields CuA" as a green insoluble pp.

Methylene derivative

CH2:O2:C4H2:CO2H. Piperonylic acid. [228°]. Occurs in para-coto bark (Hesse a. Jobst, A. 199, Prepared by oxidation of piperonal (Fittig a. Mielck, A. 152, 40). Got by heating protocatechuic acid with potash and CH2I2 (Fittig a. Remsen, A. 168, 94). Piperonylic acid is also formed by the action of KMnO on cubebin, on methystic acid (Pomeranz, M. 8, 468; 10, 790), on safrole (Eykman, R. T. C. 4, 39; Poleck, B. 19, 1096), and on the (a)-dihydride of piperic acid (Regel, B. 20, 415). Needles (from alcohol). May be sublimed. Nearly insol. cold water, m. sol. boiling alcohol. FeCl, gives a brown pp. in neutral solutions. Dilute HClAq at 170° forms protocatechuic acid. HNO3 forms nitro-piperonylic acid [172°]. Salts.—NaA' aq.
—KA'aq.—BaA', aq.—CaA', 3aq. S. 625 at 15°.
—PbA', aq.—CuA', aq.—Agà'. Quinine salt
C,H,2,N,O,HA'aq: needles, sol. hot water. Cinchonidino salt O₁₀H₂₂N₂OHA': needles (Hesse, A. 243, 147). — Ethyl ether EtA'. Oil.— Nitrile CH₂O₃:C₈H₂CN. [95°]. Formed from the oxim of piperonal and Ac₂O (Marcus, B. 24, Alcabelli, h. 24, Alcabelli, h. 25, Alc 8656). Needles, v. sol. alcohol. Alcoholic hydroxylamine at 60° forms the amidoxim CH₂O₂:C₆H₄.C(NH₂):NOH [151°] which yields B'HCl [198°], and is converted by Ac₂O into $CH_2O_2:C_0H_3.C \stackrel{NO}{<}_N > CMe [110^\circ].$

Ethylene derivative C₂H₁O₂:C₆H₃:CO₂H. [184°]. Formed by heating protocatechuic acid with ethylene bromide and KOH (Fittig, Z. [2] 7, 289; A, 168, 99). Needles (from hot water). May be sublimed. PCl, yields a product whence water reproduces ethylene-protocatechuic acid.

PCl, at 130° followed by water yields the acid C,H,Cl,O,:C,H,.CO,H [121°].-BaA', 2aq.-CaA', 2aq: monoclinic crystals.—Ethyl ether EtA'. Õil.

Di-methyl-ethylene ether C2H4(O.C6H2(OMe).CO2H)2. Formed by oxidising the ethylene ether of eugenol with KMnO, (Cahours, Bl. [2] 29, 270). Amorphous.

Reference. - NITRO-PROTOCATECHUIC ACID.

Homo-protocatechuic acid v. DI-OXY-PHENYL-ACETIC ACID.

Diprotocatechuic acid C, H, (OH), (CO,H), Formed by potash-fusion from divanillin (Tiemann, B. 18, 3494). Amorphous, sl. sol. water and alcohol. Coloured bluish-green by FeCl₃.

PROTOCATECHUIC ALDEHYDE C.H.O. i.e.

C₀H₃(OH)...CHO [4:3:1]. Mol. w. 133. [150°].
Formation. 1. From piperonal by successive treatment with PCl₃ and water at 100° (Fittig a. Remson, Z. [2] 7, 100; A. 159, 148; 168, 97). 2. By heating piperonal with dilute HClAq at 200° (F. a. R.).—3. By heating a solution of pyrocatechin in dilute NaOH with chloroform (Tiemann, B. 9, 1269; 14, 2020). - 4. By heating vanillin with dilute HCl at 200° (Tiemann, B. 7, 620) .- 5. By heating opianic acid with dilute HCl at 170° (Wegscheider, M. 3, 792).

Properties .- Flat needles (from water), v. sol. alcohol, ether, and hot water. FeCl₃ colours the aqueous solution green, changing to red on addition of Na.CO₃. Oxidised by KMnO₄ and by potash-fusion to protocatechuic acid. Gives a mirror with ammoniacal AgNO2. Combines with NaHSO.

m-Methyl derivative. C_aH_aO₃ i.e. C_aH_a(OMe)(OH).CHO. Vanillin. Mol. w. 152. [81°]. (285°). S. 1 at 14°; 5 at 80° (Tiemann a. Nagai, B. 10, 211). The fragrant constituent of the pods of Vanilla aromatica (Gobley, J. 1858, 534; Stokkebye, J. 1864, 612). Occurs also in the seeds of Lupinus albus (Campani a. Grimaldi, G. 17, 545), in raw beet-root sugar (Weger, D. P. J. 237, 146; Scheibler, B. 13, 335; Lippmann, B. 13, 662), in gum benzoïn from Siam (Jannasch a. Rump, B. 11, 1635), and in small quantity in wood (Singer, M. 3, 409). Formation.-1. Together with isovanillin, by heating guaiacol with chloroform and NaOIIAq (Reimer, B. 9, 424; Tiemann, B. 14, 2023). 2. By oxidation of coniferin or coniferyl alcohol with chromic acid mixture (Tiemann, B.7, 613).-3. By oxidation of eugenol by KMnO, (Erlenmeyer, B. 9, 273).—4. By heating calcium vanillate with calcium formate (Tiemann, B. 8, 1124) .-5. By the action of chloroform and potash on vanilie acid (Tiemann, B. 9, 1280).—6. By the action of emulsin or of boiling dilute acids on glucovanillin (Haarmann a. Reimer, C. J. 46, 1343). -7. From C₆H₃(OMe)(NO₂).CHO by reduction followed by the diazo- reaction (Ulrich, B. 18, 2573). Properties.—Monoclinio needles, v. sol. alcohol, other, CHCl₃, and CS₂; v. sl. sol. cold, v. sol. hot, ligroin. Smells and tastes like vanilla. May be sublimed. Acid in reaction, and decomposes carbonates. FeCl, gives a blue colour. Boiling aqueous HgCl₂ containing KNO₂ gives a violet colour (Nickel, Fr. 28, 247). Reduces silver solution. Oxidised by moist air to vanillic acid C_sH_sO_s. Reactions.—1. Bromine forms C_sH_sBrO_s [161°].—2. Dilute HCl at 199°

yields MeCl and protocatechnic aldehyde.— 8. Potash-fusion gives protocatechnic acid.— 4. Sodium-amalgam reduces it in alcoholic solution to vanillyl alcohol C.H.O. as a yellowish oil, and also hydrovanilloin CisHisOs [c. 225°] (Tiemann, B. 8, 1123).—5. By heating with di-methyl-aniline and ZnCl₂ it is converted into $C_{21}H_{28}N_{2}O_{2}$ [136°] (Fischer a. Schmidt, B. 17, 1895)—6. Vanillin (1 mol.) mixed with pyrogallol (2 mols.) is converted by cone. HClAq into 'pyrogallo-vanillein' CaoH18O8, which forms colourless crystals, insol. water, v. sol. alcohol, giving isomeric bluish-violet crystals by the further action of HCl (Etti, M.3, 637) .-7. Vanillin (1 pt.) boiled with diacetonamine acid oxalate (1 pt.) forms the oxalate of vanillodiacetonamine C₁₄H₁₈NO₃ (v. vol. i. p. 28).—8. Heating with Ac,O forms the acetyl derivative of vanillin, and also C6H3(OMe)(OAc).CH(OAc),[89°]crystallising in six-sided tables (Tiemann a. Nagai, B. 8, 1143) .- 9. Boiling aqueous FeCl, forms divanillin C₁₆H₁O₃ (304°), whence NaOEt and MI form C₆H₂(OMe)₂(CHO).C₆H₂(OMe)₂(CHO) [138°] (Tiemann, B. 18, 3493).—10. Chloro-acetic acid and KOHAq form C₆H₃(OMe)(OCH₂CO₂H).CHO [188°] (Elkan, B. 19, 3055). Salts.—*C₈H,NaO₃. Needles (from alcohol), sl. sol. NaOHAq.— $Hg(C_nH_1O_3)_2$: crystals, sl. sol. cold water, insol. alcohol.— $Zn(C_nH_1O_3)_2$: crystalline pp. Estimation .- Vanilla pods are extracted with ether, the extract shaken with a nearly saturated solution of NaIISO3, the aqueous layer decomposed by H.SO,, the vanillin thence extracted by ether, and the extract evaporated (Tiemann a. Haarmann, B. 8, 1115).

Acetul Acetul derivative of vanillin C₆H₂(OMe)(OAc).CHO. [77°]. Formed slowly by the action of an ethereal solution of Ac.O on sodium-vanillin in the cold (Tiemann a Nagai, B. 11, 646). Flat needles. Combines with bi-

sulphites.

Oxim of vanillin C.H. (OMe)(OH).CII:NOII. [1227] (Tiemann a. Kees, B. 18, 1661; cf. Lach, B. 16, 1786).

Phenyl-hydrazide of vanillin C_oH₃(OMe)(OH).CH:N.HPh. [105°]. Plates.

Glucoside of vanillin C,H,(OMe)(OC,H,,O,).CHO. Glucovanillin. $[192^{\circ}]$. $[a]_{\rm p} = -88.63$ at 20°. Prepared by slowly adding CrO, (8 pts.) in water (100 pts.) to coniferin (10 pts.) dissolved in water (200 pts.), and leaving the mixture to stand for 5 days (Tiemann, B. 18, 1596, 1661). Colourless needles (containing 2 aq), v. sol. water, m. sol. alcohol, insol. ether. Readily split up by dilute H.SO. or by emulsin into vanillin and glucose. Does not reduce Fehling's solution in the cold. Yields C_eH₂(OMe)(OC_eH₁₁O_s).CH:N₂HPh [c. 195°] and a lavorotatory oxim [152°], crystallising in slender yellow needles (containing aq).

p-Methyl-derivative C_sH₂(OMe)(OH).CHO[4:3:1]. Isovanillin. [116°]. Formed by oxidising acetyl-isoferulic acid with KMnO, and saponifying the resulting acetyl derivative (Tiemann a. Will, B. 14, 968). Formed also by heating opianic acid (4 pts.) with water (30 pts.) and HClAq (8 pts. of S.G. 1-17) (Wegscheider, M. 3, 789). Monoclinic pyramids, sl. sol. cold water, v. sol. alcohol and ether. May be sublimed. When warm it smells somewhat like vanillin. Its alkaline solutions are yellow.

FeCl. does not colour the aqueous solution. Reduces boiling ammoniacal AgNO. very soluble compound with NaHSO.

Di-methyl derivative C.H. (OMe). CHO.

Methyl-vanilin. [43°]. (c. 283°). Formed
from potassium vanillin and MeI (Tiemann, B. 8, 1135), and also by distilling opianic acid with soda-lime (Beckett a. Wright, C. J. 29, 164). Needles, v. sl. sol. hot water, v. sol. alcohol and ether. Smells like vanilla.

Methyl-cthyl derivative

C_sH_s(OMe)(OEt),CHO. [65°]. Formed by boiling potassium-vanillin with EtI and alcohol (Tiemann, B. 8, 1129). Prisms, v. sl. sol. hot water. Smells like vanilla.

Methylene derivative C_xH_xO₃ i.e. CH_xO₂:C_aH_x.CHO. Piperonal. Mol. w. 150. [37]. (263°). S. 2 in the cold. Formed by oxidation of piperic acid in neutral solution by KMnO, (Fittig . Mielek, A. 152, 35). Formed also by oxidation of the (a)-dihydride of piperic acid by alkaline KMnO, (Regel, B. 20, 415). Transparent prisms (from water), m. sol. hot water, v. sol. alcohol and ether. Smells much like coumarin. Forms a crystalline compound with NaHSO₃. Not affected by aqueous alkalis. Reactions.—1. By oxidation, or by boiling with alcoholic potash, it is converted into piper-onylic acid CH₂O₂:C₆H₃.CO₂H.—2. Reduced by water and sodium-amalgam to piperonyl alcohol C₈H₅O₈, hydropiperoïn C₁₆H₁₄O₈ [202], and isohydropiperoïn [138°]. AcCl converts the hydrohydropperoins into C₁₄H₁₂Cl₁O₁ [198°] (Remson a. Fittig, Z. [2] 6, 97; A. 159, 129).—3. An alcoholic solution of KCy forms piperonyloin CH₂O₂C₆H₄,CH₄(OH).CO.C₆H₄;O₂CH₂ [120°], separating from alcohol in yellow crystals [F. M. Perkin, C. J. 59, 164).—4. Very dilute HClAq at 200° forms protocatechuic aldehyde.—5. PCl, forms liquid CH₂O₂:C₈H₄.CHCl₂ (c. 235°) and C.H.(Cl,O₂, whence cold water forms dichloropiperonal C₈H₄(Cl,O₄, [90°].—6. Gaseous HCl, passed into a mixture of phenyl mercaptan and piperonal, forms CH₂O₂C₈H₄CH(SPh)₂ [48°] (Baumann, B. 18, 886).—7. Alcoholic ammonia, in presence of some HCy, forms $C_{24}H_{18}N_2O_{6}$, crystallising in prisms [213°], insol. alcohol and ether. Piperonal, heated with alcoholic NH, at 70°, forms an isomeric body [172°], crystallising in yellow needles, sol. hot alcohol, insol. water and ether (Lorence, B. 14, 791).— 8. Aqueous HCy at 65° forms a compound whence an alcoholic solution of NH, yields CH_O.C.H.CH(NH_).CN, converted by boiling HClAq into C_bH₀O_s.-9. Aniline forms, on heating, C_iH₁NO_s, crystallising in colourless needles [65°] (L.).-10. p-Phenylene-di-methyl-diamine gives C_sH₁(O_sCH_s).CH:N.C_sH_sNMe₂[110°] (Nuth, B. 18, 75°). B. 18, 575).

Oxim of piperonal CH,O,:C,H,.CH;NOH. [110°]. Needles, v. sol. alcohol (Marcus, B. 24,

Phenyl-hydrazide of piperonal CH_O,C,H_CH.N_HPh. [100°] (M,); [103°] (Rudolph, A. 248, 103). Yellow needles. PROTOPINE C₂₂H₁₂NO₂. [202°]. An alkaloid occurring in very small quantity in opium,

and obtained from the mother-liquors after the separation of morphine by Gregory's process (Hesse, Z. [2] 7, 653; A. Suppl. 8, 318). rated from cryptopine by ppn. of the solution of

the mixed hydrochlorides with conc. HClAq, the protopine salt adhering to the sides of the vessel. Crystalline powder (from alcohol), insol. water, sl. sol. hot alcohol, m. sol. chloroform. The alcoholic solution is alkaline in reaction. Sl. sol. ether, separating in spherical groups of prisms. Sl. sol. KOHAq and NH, Aq. FeCl, gives no colour. HNO, forms a colourless solution, which turns yellow on warming. H₂SO₄ containing ferric sulphate gives a dark-violet solution, turned dirty brownish-green at 150°. The salts have a bitter taste, and do not gelatinise .-

B'_H_PtCl, 2aq: yellow crystalline pp.
PRUSSIAN BLUE v. FERRIC FERRICYANIDE, vol. ii. p. 834; and Potassium-ferrous ferri-

CYANIDE, vol. ii. p. 339.

PRUSSIC ACID v. CYANHYDRIC ACID, vol. ii. p. 300.

PSATYRIN v. HARTIN.

PSOROMIC ANHYDRIDE O.H.O.? [264°]. Occurs in Psoroma crassa, a lichen growing in Sicily (Spica, G. 12, 431). Needles, sol. alcohol and ether, insol, benzene. Yields C. H13 AgO10 as a flocculent pp

PSYCHOSINE. A substance got, according

to Thudichum (J.m. [2] 25, 19), from brain. PTEROCARPIN $C_{20}H_{10}O_{s}$. $[152^{\circ}]$. $[a]_1 = -211^{\circ}$ in 46 p.c. chloroform solution. Obtained by mixing powdered sandal wood (Pterocarpus santal line). talinus) with slaked lime, and extracting with ether. The residue is crystallised from alcohol, and the homopterocarpine dissolved in CS2, which leaves the pterocarpine (Cazencuve a. Hugounenq, A. Ch. [6] 17, 115). Square tables (from CHCl₂), insol. water, m. sol. hot alcohol and hot CS₂. Insol. acids and conc. KOHAq, even on boiling. Bromine forms C₂₀H₁₃BrO₈, crystallising in yellowish needles.

Homopterocarpin carpin $C_{24}H_{24}O_6$. [82°-86°]. Obtained as above (C. a. H.). $[\alpha]_1 = -199^{\circ}.$ Long needles (from boiling alcohol), insol. water,

sol. ether, v. sl. sol. cold alcohol.

Reactions.—1. Bromine gives C₂₄H₂₃BrO₄ and C₂₄H₁₈Br₆O₆ [270°].—2. On distillation it is largely split up into phenols resembling creosote, and a small quantity of pyrocatechin. - 3. Distillation over zinc-dust gives benzene, toluene, ethylene, and CO.—4. HCl gives MeCl and a resin.—5. HI gives MeI.—6. Potash-fusion gives phloroglucin. - 7. Fuming HNO, gives oxalic acid and tri-nitro-orcin [162°]. Not acted upon by sodium-amalgam, phenyl-hydrazine, and Ac.O.

PTOMAINES. The name 'ptomaines' was first applied to poisonous organic bases obtained from dead bodies (πτῶμα, a corpse), but is now usually given to poisonous organic bases formed in the putrefaction of any kind of animal matter. In extracting ptomaines no reagents that would decompose proteids may be used. The bases may be extracted by alcohol, and purified by ppn. with phosphomolybdic acid. In presence of a little HCl the ptomaines are fairly stable, and the solution can then be evaporated and the hydrochlorides extracted from the syrupy residue by absolute alcohol. By this method neuridine

CH(OH), CH, NMe,OH (vol. iii. p. 444), a base isomeric with ethylene-diamine, neuridine C.H., N2, gadinine C,H,, NO2, triethylamine, dimethylamine, and trimethylamine. Garcia (H. 17, 543) got hexamethylene-diamine C.H. Herring-pickle contains choline, NMe, and NH, Me. By the putrefaction of the herring NMe, NH2Me, cadaverine C.H16N2, putrescine C4H12N2, and gadinine C,H₁,NO₂ are formed (Bocklisch, B. 18, 1922). Gautier and Etard (C. R. 94, 1600) from putrid mackerel and putrid horse-flesh obtained a collidine dihydride C,H12N, parvoline CoH13N, and a base C17H38N. In the putrefaction of proteids poisonous bases are formed in the first five or six days, and are destroyed by further progress of putrefaction. The highly poisonous methyl-guanidine is formed by the action of putrefactive bacteria on beef-broth at 38° (Bocklisch, B. 20, 1441). From human corpses Brieger obtained tri-methyl-oxyethyl-ammonium hydroxide C₃H₁₅NO₂ or CH₂(OH).CH₂NMe₃.OH (choline or neurine, vol. iii. p. 498), neuridine (choine or netrine, vol. iii. p. 498), neuridine $C_3H_{11}N_{2}$, cadaverine $C_3H_{12}N_{2}$, putreseine $C_4H_{12}N_{2}$, saprine $C_3H_{12}N_{2}$, trimethylamine, methyl-guanidine, tetanine $C_1H_{22}N_{2}O_4$, mydiatoxin $C_4H_{13}NO_2$, and mydaleine (Brieger, loc. cit.; cf. Selmi, Rend. Accad. Sci. Bologna, 1872; Schwanert, B. 7, 1332; Guareschi a. Mosso, J. pr. [2] 27, 428; 28, 504; G. 13, 493; Rockurte Ar. El. (314, 1041). Petominas are Beckurts, Ar. Ph. [3] 14, 1041). Ptomaines are often produced in animal bodies which, after brief exposure, have been excluded from the air ; e.g. corpses, sausages, and tinned meat. A crystalline ptomaine can be obtained from the body after arsenical poisoning (Husemann, Ar. Ph. [3] 16, 169; 19, 415). The alcoholic solution of hydrochlorides of ptomaines may be ppd. by an alcoholic solution of HgCl2; after twenty-four hours' standing, the pp. is boiled with a large quantity of hot water, which leaves the compounds of peptones and albuminates undissolved.
The hot filtrate deposits the mercury double salt of choline (neurine) while the mother-liquor contains the remaining bases. Picric acid added to an aqueous solution of the hydrochlorides ppts. neuridine picrate, while the mother-liquor deposits, on evaporation, broad needles of choline picrate C₅H₁₃NOC₆H₂(NO₂)₃OH. Cadaverine and putrescine can be separated by means of their aurochlorides. Saprine is isolated by means of its platinochloride. To distinguish a ptomaine from a vegetable alkaloid, Brouardel a. Boutmy (C. R. 92, 1056; cf. Tanret, C. R. 92, 1163) add a few drops of the solution of the sulphate of the alkaloid to potassium ferricyanide mixed with FeCl₃: a dark-blue pp. is formed if a pto-maine be present, while the vegetable alkaloids (except morphine, veratrine, eserine, aconitine; and ergotinine) have no action. The test is, of course, given by many other reducing agents. This ptomaine reaction is given (slowly) by a poisonous liquid alkaloid extracted by Stas's method from the intestines of persons who died of cholera (Villiers, C. R. 100, 91). Pouchet (C. R. 97, 1560; cf. Gautier, B. C. 1882, 710; Béchamp, C. R. 94, 973) obtained from urine and faces some alkaloids closely resembling by absolute alcohol. By this method neuridine hydrochloride can readily be obtained. By the putrefaction of proteids Brieger (Two monographs: Ueber Ptomaine, Berlin, 1885; cf. Gautier, Bl. [2] 48, 10) obtained tri-methylographs: Gautier, Bl. [2] 48, 10) obtained from urine and fæces some alkaloids closely resembling the ptomaines got by putrefaction of proteids of accompanies of alcohol, the lead being finally removed by H2S, and the liquid dialysed. C.H.NO. is liquid and dialyses with difficulty; it exhibits the alkaloidal reactions, is resinified by HCl, and reduces platinic chloride. The base C.H., N.O. or C,H, N,O2 is crystalline, and passes through the membrane; it is insol. ether, nearly insol. alcohol, is feebly alkaline and yields crystalline salts. From the dialysate the platinochlorides of two crystalline unstable bases C, H12N2O, and C,H, N,O, can be got. Urine which had a tendency to deposit cystin and the fæces of the same patient contained cadaverine and putrescine (Baumann, H. 13, 562; cf. Dupré a. Bence-Jones, Pr. 15, 73; Stadthagen a. Brieger, Ar. pathol. Anat. 115, pt. 3). These diamines appear to be absent from normal urine, but present in cholera.

Cadaverine is Pentamethylene-diamine, vol. iii. p. 805.

Putrescine is Tetramethylene-diamine.

Mydaleïne is extremely poisonous, while

gadinine is not poisonous.

Mydine C,H, NO. Occurs in putrid corpses (Brieger, Ptomaine, iii. 25). Has an ammoniacal odour and reduces gold chloride. Not poisonous. -B'C,H,N,O,. [195°]. Broad prisms.

Base C,H,NO,. Occurs in decaying horse-

flesh, four months old (Brieger). Acid in reaction. Poisonous. Does not form a picrate.—B'HAuCl., [176°]. Needles or plates.

Typhotoxin C, H1, NO2. Formed by the action of the typhus bacillus on muscle (Brieger, Ptomaine, iii. 86). Poisonous base.—B'HAuCl. [176°]. Prisms.

Mydatoxin C_bH₁₃NO₂. Occurs in decaying horse-flesh and corpses (B.). Poisonous. Strongly

alkaline.—B'_H,PtCl, [193°]. V. e. sol. water.

Tetanine C₁H₃N₂O₄. Occurs in decaying corpses (Brieger, B. 19, 3120), and is formed by the action of the tetanus bacillus on beef. Very

poisonous base.—B'H,PtCl_s. Plates.

Base C,H₁₁N. (c. 100°). Accompanies tetanine, and also produces convulsions (B.). Volatile liquid. Its hydrochloride is crystalline [205°].—B'HAuCl₄. [130°].—B'₂H₂PtCl₆. Plates, decomposed at 240°.

Base C₃₂H₃₁N. Oily ptomaine, smelling like hawthorn (Delezinier, Bl. [3] 1, 178). In prosence of air it acts chemically and physiologically like veratrine. Insol. water, sol. alcohol and ether. Its salts are deliquescent.

Base C₃H₁₁NO₂. [156°]. Occurs in putrid flesh and putrid fibrin (E. a. H. Salkowski, B. 16, 1192). Crystalline powder, v. e. sol. water. Not poisonous. - B'HCl: crystals, v. e. sol. water.

-B'HAuCl, aq: yellow crystals.

Base C₁₁H₁₂NO₂. Erysipeline. Occurs in urine in erysipelas (Griffiths, C. R. 115, 667). Prisms, sol. water. Very poisonous.

Base C₁₂H₁₃NO. Occurs in urine in puerperal fever (G.). Crystalline and poisonous.

Base C₁₂H₁₃N. A product of the decomposition of albumen by Bacterium allii, which is found in decaying onions (A. B. Griffiths, C. R. 110, 416). Minute deliquescent needles (from water), smelling like hawthorn.-B'₂H₂PtCl₄: crystalline, sol. hot water.

Base C, J.H., N.O. Occurs in urine of victims to glanders (A. B. Griffiths, C. R. 114, 1382). White crystals. Poisonous. Forms crystalline salts.

Base C₂₀H₂₆N₂O₅. Occurs in urine in cases of pneumonia (G.). Minute needles, forming an

alkaline aqueous solution [a]₀ = 23.5°.

Base C_sH₁₁N. (202°). S.G. 2 9865. Extracted, together with a base CieHisN from putrid cuttlefish (De Coninck, C. R. 106, 858, 1604; 108, 58, 809; 110, 1339; 112, 584). Mobile, stronglysmelling liquid, v. sol. water, alcohol, and ether. Turns brown in air. Appears to be a propylpyridine, as it yields nicotinic acid on oxidation by dilute KMnO, at 90°.—B'HCl: deliquescent radiating flass.—B'_HPtCl_e. Converted by hot water into B'_PtCl_e, a nearly insoluble brown b'₂H₁H₃Cl₈. B'HBr. B'₂H₁H₃Cl₈. B'₂H₁H₃Cl₈. B'₄H₁N₂Cl₈. B'₄McI. Needles, v. e. sol. alcohol. Base C₁₀H₁₃N. (230°). Formed as above. Liquid, smelling like furze. Resinified by air.—

B'HBr. White deliquescent needles .- B'HCl. --B'₂H₂PtCl₄. — B'₂PtCl₅. [206"]. — B'HAuCl₄: yellow pp., decomposed by hot water.

. Base C₁₀H₁₃N. (200°). Extracted by Stas's method from fibrin that has putrefied for two months (Guareschi a. Mosso, J. pr. [2] 27, 428; J. Th. 1887, 487). Yields the alkaloidal reactions. Smells like pyridine. Acts physiologically like curare.—B'2H_PtCl₂: rose-red crystals.

Base C₁₄H₂₀N₂O₄. [250°]. Formed in the putrefaction of fibrin, from which it can be extracted, together with the liquid alkaloid C10H13N, by chloroform and ether (Guarcschi, G. 17, 509). Tables (from alcohol), sol. water and alcohol, v. sl. sol. chloroform. Its aqueous solution is neutral. Griffiths (Bl. [2] 7, 250; C. R. 113, 656) got, from urine of patients suffering from erysipelas, a crystalline ptomaine 'erysipeline' C11 K13 NO3, sol. water, and very poisonous. gives the alkaloidal reactions.

The term leucomaines (λεύκωμα, white of egg) is applied by Gautier (Sur les Alcaloïdes des Tissus Animaux, Paris, 1886) to alkaloids occurring in the tissues of living animals. From fresh beef and Liebig's extract of beef he obtained xanthocreatinine $C_2H_{10}N_1Q$, crysocreatinine $C_2H_1N_1Q$, amphicreatinine $C_2H_1N_1Q$, pseudoxanthine $C_1H_1N_1Q$, and two feeble bases $C_{11}H_{12}N_{12}Q_3$ and $C_{12}H_{12}N_{11}Q_4$, both crystallising in tables.

Xanthocreatinine C5H10N4O. Thin sulphuryellow tables, v. e. sol. water, sol. boiling alcohol. Gives an odour of roast meat when heated. Resembles creatinine.

Chrysocreatinine C.H.N.O. Orange crystals, with feebly alkaline reaction. Sl. sol. water, Resembles creatinine.

Amphicreatinine C₀H₁₀N,O₄. Yellow prisms, sl. sol. water. A weak base, resembling crea-

Pseudoxanthine C.H.N.O. Yellow orystalline powder, sl. sol. cold water, sol. HClAq and NaOĤAq. Reacts with HNO, and KOH like vanthine.

Carnine v. vol. i. p. 710.

PTYALIN v. vol. ii. p. 545.
PTYCHOTIS OIL. The essential oil got from the seeds of Ptychotis ajowan, an umbelliferous plant growing in Central India, contains thymoland a terpene C₁₀H₁₈ (172°) S.G. ¹² ·854 (Stenhouse, C. J. 9, 234; cf. Haines, C. J. 8, 289).
PULEGIUM OIL. The essential oil of Puls-

gium micranthum, growing on the Steppes of Southern Russia, contains oily C. H. O (227°) S.G. 11 .932 (Butlerow, J. 1854, 594). It yields acetic and valeric acid when fused with potash. The oil of Mentha pulegium is described under

PULVIC ACID $C_{18}H_{12}O_{5}$ i.e. $CO_{2}H.CPh; C < \stackrel{C(OH):CPh}{O} \stackrel{CO}{CO}$. [215°]. Prepared

by the action of cold NaOHAq on a solution of the anhydride in acctone, and also by boiling vulpic acid with milk of lime (Spiegel, B. 13, 1630, 2219; 14, 1686; 15, 1550; A. 219, 1). Orange crystals or yellow plates (containing EtOH), sol. alcohol and ether, sl. sol. water. Decomposed by baryta-water into phenyl-acetic and oxalic acids. Alkaline KMnO, oxidises it to phenyl-glyoxylic and oxalic acids. On reduction by zinc-dust and NH3Aq it gives a mixture of carboxy-cornicularic acid (C1, H1,O3), cornicularic carboxy-cornicularic acid (C₁,H₁₁O₃), cornicularic acid (C₁,H₁₀O₃), and the two dihydrides of cornicularic acid (C₁,H₁₀O₃).

Salts.—BaA" and; golden plates.—AgHA"; small prisms.—Ag,A" aq: long needles.

Methyl ether v. Vulpic acid.

Ethyl ether Eth'. [128°]. Prepared by

dissolving the anhydride in alcoholic potash.

Methyl derivative of the methyl ether $C_{1s}H_{1o}Me_2O_3$. [139°]. Colourless needles. An hydride $C_{1s}H_{1d}O_4$ i.e.

CO.O.C:CPh CO. [221°]. Formed, together with MeOH, by heating vulpic acid at 200°. Colourless needles, sl. sol. alcohol, insol. water. Converted by ammonia into C₁₈H₁₁(NH₂)O₄ [220°] crystallising in yellow prisms.

PUNICIN. The purple of the ancients. Extracted from Purpura capillus and other shell-

fish which yield a colourless secretion which becomes purple on exposure to sunlight (Schunck, C. J. 35, 589; 37, 613). Obtained in Central America from Purpura patula. Yarn dyed by the Indians is warmed with HCl and then with ether. The colouring matter is then extracted with aniline, which on cooling deposits punicin as a crystalline powder, insol. boiling alcohol and ether, sl. sol. benzene and HOAc. Its solution in aniline shows an absorption band between C and D, with a sharp edge towards C. The band resembles that of indigo, but it disappears sooner on standing. In phenol it forms a sky-blue solution. Its solution in conc. H.SO. shows an absorption band between D and E this disappears on standing, the liquid becoming bright green. Water precipitates the purple from this solution, so that a sulphonic acid is not formed. Punicin begins to sublime at 190°. It is hardly attacked by HNO₄ (S.G. 1·2) or by aqueous CrO₃. With bromine it reacts, forming a body which crystallises from alcohol in yellow needles. Punicin dissolves in aqueous SnCl, but is deposited again on exposing the solution to air.

PURPLE OF CASSIUS. A purple-coloured solid, obtained by adding SnCl,Aq to AuCl,Aq in presence of a reducing agent; v. Tin, oxides or, in this volume.

PURPURIC ACID C,H,N,O,. Not known in the free state.

Salts. - (NH4)HA" aq. Murexide. Formed by heating ammonium dialurate; by oxidising uranil with HgO; and by adding ammonia or ammonium carbonate to a mixture of

alloxan and alloxantin (Prout, A. Ch. 11, 48; Kodweiss, P. 19, 12; Liebig a. Wohler, A. 26. 319; Fritzsche, J. pr. 16, 380; 17, 47; Beilstein, A. 107, 176; Laurent, C. R. 35, 629; Gregory, A. 33, 334). Garnet-red four-sided prisms with golden-green lustre; when dried in vacuo it forms a brown powder. M. sol. hot water, forming a purple solution, insol. alcohol and ether. Decomposed by acids with formation of uranil and alloxan. The absorption spectrum has been studied by Hartley (C. J. 51, 199) .- KHA". Crystals resembling murexide, forming in cold KOHAq a blue solution decolourised by heat.— NaHA".—BaA" 3aq; dark.green powder.— AgHA" 1 aq: brownish-red powder.—Ag2A".

Isopurpuric acid v. TRI-NITRO-PHENOL, Re-

action 5.

Metapurpuric acid v. (a)-DI-NITRO-PHENOL,

PURPUREO CHROMIUM SALTS v. CHROM-AMMONIUM SALTS, vol. ii. 159-60.

PURPUREO-COBALT SALTS v. COBALT-AMINES, vol. ii. pp. 227-8. PURPUREO-RHODIUM SALTS

DIUM-AMMONIUM COMPOUNDS.

PURPURIN v. TRI-OXY-ANTHRAQUINONE.

PURPURIOR 2. IRI-OXY-ANTHIBAGOINOSE.

PURPUROGALLIN C. H. 10. Pyrogalloguinone. [256]. Formed by the slow oxidation of pyrogallol (Struve, A. 163, 162; Girard,
Z. 1870, 86; Wichelhaus, B. 5, 848; De Clermont a. Chautard, C. R. 94, 1362; 102, 1072,
Victoria C. 100, 1077; Lagy J. 27 Nietzki a. Steinmann, B. 20, 1277; Loew, J. pr. [2] 15, 322). Formed also by the action of aqueous KNO2 on gallic acid (Hooker, B. 20, 3259). Obtained also from pyrogallol and quinone (Wichelhaus, B. 5, 847; Nietzki, B. 18, 1278). Prepared by adding a solution of K_a FeCy_g (87 g.) in water (330 c.c.) to pyrogallol (20 g.) dissolved in cold water (330 c.c.), and filtering after half an hour; the yield is small (3 g.). Dark-brown needles (from alcohol). May be sublimed. V. sl. sol. water, sl. sol. alco-hol, m. sol. ether. Reduces AgNO, and Fehling's solutions. H.SO, forms a crimson solution changed to violet by HNO, Ammonia forms a blue solution, changing through green to dark rellow. Yields naphthalene on distillation with zinc-dust. According to De Clermont and Chautard purpurogallin yields Na,A' os crystal-lising in deliquescent needles, Ba,A' os crystalline plates, C₂₀H₁₂Br₄O₀ as red needles [204°] and C₂₀H_{1.}Ac₄O₀ [186°]. By heating with H₂SO₄ these chemists obtained SO2 and C20H12O10, which crystallised in brown needles forming a blue solution in KOHAq.

PURPUROXANTHIN v. m-DI-OXY-ANTHRA-

PURREIC ACID v. EUXANTHIC ACID. PUTREFACTION v. FERMENTATION.

PUTREFACTIVE ALKALOIDS v. PTOMAÏNES. PUTRESCINE v. TETRA-METHYLENE-DIAMINE.

PYKNOMETER. This name is sometimes given to various forms of the specific gravity bottle, for determining the relative densities of

liquids (cf. Densities, relative, vol. ii. p. 373).
PYRANIL-PYROIC ACID C₁₀H₁₀NO(CO₂H). [165°]. Formed by heating phenyl-amido-pyrotartaric acid CO.H.CH, CMe(NHPh).CO.H a little above its melting point for some time (Reissert a. Tiemann, B. 19, 622; 21, 1942, 3257; 22, 2281; 24, 314). Crystalline powder, sl. sol.

water, alcohol, and ether. Converted by heating strongly into the phenyl-imides of citraconic acid and of phenyl-amido-pyrotartaric acid. According to Anschütz (B. 21, 3252; 22, 731; 23, 895, 2979; A. 246, 115; 248, 269), pyranilpyroïc acid is the mono-anilide of mesaconic

PYRAZINE. This name is used to denote the ring NCH:CH>N.

Pyrazine hexahydride C4H10N2 NH CH₂CH₂ NH. Piperazine. Di-ethylenediamine. [104°-107°]. (137° uncor.). Formed from ammonia and ethylene bromide (Cloez, Instit. 1843, 213) or ethylene chloride (Natanson, A. 92, 48; 98, 291; Hofmann, Pr. 10, 224; 11, 278; B. 23, 3297). Formed also by boiling NO.C. H. N. CH. CH. N. N. With alcoholic potash (Bischler, B. 24, 717). According to Majert a. Schmidt (B. 24, 241), it is not identical with spermine. Glittering tables (from water). May be sublimed. Strongly alkaline and absorbs CO₂ from the air.

Reactions .- 1. Aqueous NaOCl, saturated with Cl, forms ClN CH₂·CH₂·NCl [71°], crystallising in prisms, v. sl. sol. water, v. sol. alcohol (Schmidt a. Wichmann, B. 24, 3243). This body explodes at 80°-85°. Bromine water forms the corresponding di-bromo-piperazine, which is very unstable. -2. Diazobenzene chloride and NaOHAq form Ph.N. N:C, H. N.N. Ph [129°] (S. a. W.). - 3. Beneoic aldehyde yields the compound (N:C,H,:N):CHPh [247] (Schmidt a. Wichmann, B. 24, 3212). - 4. Quinone forms an amorphous violet-brown body, almost insol. alcohol. -5. Hydroquinone in alcoholic solution forms $C_4H_{10}N_2C_4H_0O_2$, crystallising in needles [195°].—6. Phenol forms $C_4H_{10}N_2$ PhOH [101°], crystallising from spirit in prisms, v. sol. water.-7. Oxalic ether at 110° reacts forming the ether CO₂Et.CO.N.C.H.; N.CO.CO₂Et [124°] crystallising in broad needles (S. a. W.).—8. p-Chloro-nitro-benzene at 150° gives the compound NO₂, C., H., N.C., H., NO₂ [248°] (Schmidt a. Wichmann, B. 24, 3240).

Salts.—B"H,Cl, aq: needles, v. sol. water.— B"H,PtCl, -B"2HAuCl, -B"H,HgCl, : stellate Britin.—D Zimudi.—D Halleri, Sociale groups of needles (Sieber, B. 23, 326).—
B"C,H.(NO₂),OH: yellow needles.—Carbonate: [162°-165°].—Urate: B"C,H,N₄O₃. The phosphate and the bismutho-iodide are crystalline.

Di-acetyl derivative [138.5°]. (above 310°). Formed from piperazine and Ac₂O. Needles, v. e. sol. water and alcohol.

Nitrosamine NO.N:C,H,:N.NO. (Ladenburg, B. 24, 2640; Schmidt, B. 24, 3245; HOAc to NH, N.C.H, N.NH, which crystallies in needles [c. 100°] (228°), and yields B'HCl, B'C,H,N,O,, an amorphous di benzoyl derivative, and reacts with benzoic aldehyde, forming CHPh:N.N:C,H,:N.N:CHPh [205], which crystallises in pearly plates.

PYRAZOLE C,H,N, i.e. CH:CH>NH. [70°]. (187°). Formed by heating the tri-carboxylic acid produced by saponification of the product slowly adding H,SO, to aqueous KNO, under an

of direct addition of diazoacetic ether and of direct addition of diszoncesic etner and accetylene dicarboxylic ether (Buchner, B. 22, 2165). Formed also by heating hydrazine hydrate (10.8 g.) with epichlorhydrin (10 g.) and ZnCl₂ (11 g.) (Balbiano, B. 23, 1193). Needles, v. sol. cold water, forming a neutral solution, sol. alcohol and ether. Gives a white pp. with HgCl., and also with ammoniacal AgNO.

Salts .- B'HCl. Hygroscopic prisms. B',H,PtCl, 2aq. At 210° it is split up into HCl and $(C_3H_3N_2)_2PtCl_2$, a light-yellow powder. — AgC₃H₃N₂ sl. sol. water. — B'C₆H₂N₂O₇. [160°]. PYRAZOLE BLUE C20H18N,O2 i.s.

N.NPh.CO CO.NPh.N -CMe. Formed by oxidation С́Ме — С́=С _ of di-oxy-di-phenyl-di-methyl-dipyrazyl (Knorr, A. 238, 172; B. 25, 765). Sol. chloroform, conc. H₂SO, and HOAc. Its spectrum resembles that of bodies of the indigo group. Decomposes about 230°. Its sulphonic acid, got by the action of Br on di-oxy-di-phenyl-di-methyl-dipyrazyl disulphonic acid, is destroyed by excess of bromine (Möllenhoff, B. 25, 1949).

o-PYRAZYL-BENZOIC ACTD C10H8N2O2 i.e. CH:N CH:CH>N.C.H..CO.H. [139° cor.]. Formed by oxidising o tolyl pyrazole with KMnO, (Balbiano, G. 19, 123). Yellow needles (from dilute alcohol) .- BaA' ...

Ethyl ether EtA'. (309° i.V.). p-Pyrazyl-benzoic acid. [265°]. Got in like manner from p-tolyl-pyrazole.—NaA'. BaA'. Ethyl ether EtA'. [62°]. Tables.

202. [149°]. (above 360°). S. (alcohol) 1:87 at 16°; 3:08 at 78°; S. (toluene) 16:5 at 18° (Bechi, B. 12, 1978). Occurs in coal tar (Graebe, A. 158, 285). Monoclinic tables (Fittig a. Hintz, 1978). B. 10, 2143), v. e. sol. CS2 and ether. Yields pyrene-quinone and pyrenic acid on oxidation. ShCl, at 360° forms CCl4, C15Cl10 [above 800'], C1,Cl10 [above 300°], and other bodies (Merz a. Weith, B. 16, 2880). Bromine forms crystalline C_{1e}H_zBr₄ and C_{1e}H_zBr₅ (Graebe).

Picric acid compound C, H, O, H, N,O, [222]. Red needles (from alcohol), v. sl. sol.

cold alcohol, m. sol. ether, v. sol. benzene. Hexahydride C₁₀H₁₀. [127°]. Formed by heating pyrene with HIAq and P at 200°. Needles, v. e. sol. ether and boiling alcohol. alcoholic solution is not ppd. by picric acid.

Chloropyrenes. The following chloro-pyrenes are formed by passing Cl into a solution of pyrene in chloroform. They are separated by fractional crystallisation from alcohol, chloroform, and xylene (Goldsch.niedt a. Wegscheider, M. 4, 237).

C_{1c}H_cCl. [119°]. Golden needles, forming in H₂SO, a solution with violet fluorescence. Yields C_{1c}H_cClC_cH₁N₁O₁. [177°].
C_{1c}H_cCl₂. Two di-chloro-pyrenes [156°] and

[196°]. C16H,Cl. [257°]. White needles. ClaH.Cl. [above 830°]. Needles.
Nitropyrene ClaH.NO. [150°]. Formed by ethereal solution of pyrene (Goldschmiedt, M. 2, 580). Yellow needles (from alcohol), sl. sol. cold alcohol.

Dinitro-pyrene C_{1*}H₃(NO₂)₂. Formed from pyrene and MNO₃ (S.G. 1·45). Yellow needles (from HOAc). Reduced by tin and HCl to diamido-pyrene (Jahoda, M. 8, 449).

Tetra-nitro-pyrene C_{1*}H₄(NO₂)₄. [above 800°]. Yellow needles (from HOAc), nearly insol. alcohol.

insol. alcohol.

Amido-pyrene C₁₈H₂.NH₂. [116°]. Got by reducing nitropyrene. Needles, sl. scl. water.—
B'₂H₄SO₄ (dried at 100°).—B'HCl. Its solution dyes fir wood red.

PYRENE CARBOXYLIC ACID $C_{16}H_{9}.CO_{2}H$. [287°]. Formed by fusing its nitrile with potash (Goldechmiedt a. Wegscheider, M. 4, 256). Needles, sl. sol. water. Resolved by heat into pyrene and CO.—CaA'₂ aq.—BaA'₂ 2\(\frac{1}{2}\) aq.

Nitrile C₁₈H₂CN. [150°]. Formed, together with the privale of the discripacytic gold.

gether with the nitrile of the dicarboxylic acid, getner with the nitrie of the disarboxylic acid, by heating potassium pyrene disulphonate with KOy or K, FeCy_s. Needles (from alcohol). The solutions of this body show green fluorescence.— (O₁,H_{*}N₂,C_{*}H_{*}N₃O_{*}. [134°]. Red needles, decomposed by alcohol.

Fyrene dicarboxylic acid C_{1s}H_s(CO₂H)₂.

[above 300°].

Nitrile [above 300°]. C_{1e}H_s(CN)₂. Formed as above. Yellow powder. Its solutions show green fluorescence.

PYRENE-KETONE C13H8O i.s.

[1:1] $C_{10}H_s < CH > CO$. [142°]. Formed by

distilling pyrenic acid with slaked lime (Bamberger a. Philip, B. 19, 1996, 3040; 20, 371; A. 240, 178). Golden tables (from dilute alcohol), volatile with steam. Reduced by zinc and HCl to C₁₂H_s(CH.OH). Oxidised by KMnO₄ to naphthalene (1,1')-dicarboxylic acid.

PYRENE-QUINONE C, H,O, i.e.

(Bamberger a. Philip, B. 20, 369; A. 240, 166). [c. 282]. Formed by oxidation of pyrene by chromic acid mixture (Graebe, A. 158, 295; Goldschmiedt, M. 4, 309). Red needles (from HOAc), sol. aqueous NaHSO₃, v. sl. sol. alcohol and ether. Yields pyrene on distillation with zinc-dust. Bromine forms C₁₄H₂Br₁O₂ and the control of the control o C16H2Br3O2. Its alcoholic solution is turned claret-colour by a little NaOH. Reduced by zinc-dust and ammonia to hydropyrenequinone or pyrene-hydroquinone C18H10O2, which forms golden crystals exhibiting a dark-blue fluorescence in alcoholic solution, and yielding C18H8Ac2O2 [167°].

PYRENE SULPHONIC ACID C, H, SO, H. Got by fusing the disulphonic acid with potash (Goldschmiedt a. Wegscheider, M. 4, 242).— KA'aq: minute needles (from dilute alcohol).

PYRENE DISULPHONIC ACID C,H,(SO,H). Formed by heating pyrene with H,SO. Sticky mass, v. sol. water, sl. sol. alcohol, insol. ether.—K,A"2½aq.—BaA"8½aq.— CaA"2aq : yellow powder.

Formed by the oxidation of pyrene or pyrenequinone by chromic acid (Bamberger a. Philip, quinone by chromic acta (Damberger at 1 https://dx.1995.3036; 20, 369; A. 240, 168). Pale-yellow plates, blackened above 250°. V. sl. sol. alcohol. H₂SO, forms an orange solution. Oxidised by KMnO, to naphthalene tetra-carboxylic acid. Reacts with hydroxylamine. Phenyl-hydrazine forms C₁₅H₈O₄(N₂HPh) 2aq, crystallising in yellow prisms. - BaA"aq. Ag, A": amber-yellow pp.

 $C_{13}H_6O<_{CO}^{CO}>0.$ Anhydride Yellow needles, formed by boiling the acid with HOAc.

Imide C₁₃H₆O CO NH. Yellow plates,

got by dissolving the acid in NH₃Aq.

PYRENOLINE C₁₀H₁₁N. [153°]. Formed by heating amido-pyrene hydrochloride with nitrobenzene, glycerin, and H₂SO₄ (Jahoda, M. 8, 442). Golden scales (from alcohol), v. sol. water,

442). Golden scales (from alconol), v. sol. water, forming solutions which exhibit green fluorescence.—B'HCl. [270°].—B',H,P'tCl., [above 290°].—B'HSQ., aq. [246°].—B'C,H,N,O,. Decomposes at 260°.—B'MeI. [212°].

PYRIDANTHRILIC ACID C,H,N,O, i.e. [2:1]CO,H,C,H,N,H,CO,C,H,N(CO,H), [265°].

Formed by the action of alkaline KMnO, on solutions the scale of t cyclothraustic acid derived from a-diquinoline (Weidel a. Strache, M. 7, 289; 8, 197). Micaceous plates, sl. sol. hot water. Yields isocinchomeronic and anthranilic acids on oxidation.

PYRIDAZINE. The ring CH CH.CH CH. (Ach, A. 253, 46; cf. Knorr, A. 236, 295).

PYRIDINE C₃H₅N i.e. N CH:CH CH. Mol. w. 79. (116°) (Schiff, B. 19, 566); (114°) Mol. W. 79. (116°) (Schiff, B. 19, 566); (114°) (Ladenburg, A. 247, 4); (116·5°) (Perkin, C. J. 55, 701). S.G. 21·0033 (L.); \(\frac{1}{16}\) -9855; \(\frac{3}{2}\) -9778 (P.). M.M. 8·761. H.F. p. -19,370 (Thomsen); 7,117 (Ramsay, C. J. 35, 696). H.F. v. -20,530 (Thomsen, Th.). S.H. 418 (Colson, A. Ch. [6] 19, 408). S.V. 89·4 (Schiff); 91·6 (Ramsay). Occurs in bone oil, in coal-tar, and in target by distilling hituminous shele and reactions. got by distilling bituminous shale and peat (Anderson, Tr. E. 16, 4; 20 [2] 247; P. M. [4] 2, 257; A. 80, 55; 96, 200; 105, 335; Greville Williams, P. M. [4] 8, 24; Church a. Owen, C. N. 2, 146; P. M. [4] 20, 110; Schulze, B. 20, 409). Occurs also in tobacco smoke, and, in small quantity, in fusel oil (Haitinger, M. 3, 688).

Formation .- 1. By heating isoamyl nitrate with P.O. (Chapman a. Smith, A. Suppl. 6, 329). 2. By distilling its carboxylic acids with lime .-3. By distilling oxytrialdine and oxytetraldine with soda-lime (Schiff, A. Suppl. 6, 21).-4. With other bases by heating glycerin with ammonium other cases by neating giverin with ammonium phosphate (Stöhr, *J. pr.* [2] 45, 23).—5. By passing ethyl-allyl-amine over PbO at 450° (Koenigs, *B.* 12, 2344).—6. By heating piperidine with H.SO, at 300° (K.), with nitro-benzene (4) pts.) at 260° (Lellmann a. Geller, *B.* 21, 1921). or with AgOAc and 10 p.c. HOAc at 180° (Tatel, B. 25, 1621) .- 7. Together with mono- and disubstitution products by the action of Br on

acetyl-piperidine (Hofmann, B. 16, 587).—8. By heating sodium-pyrrole with NaOMe and CH₂I₂ in sealed tubes at 200° (Dennstedt a. Zimmermann, B. 18, 8316).—9. From anhydroegonine, by treatment with conc. HCl and distillation of the product with zinc-dust (Einhorn, B. 22, 1365).

Purification.—By ppg. the crude base (20 g.) dissolved in (100 g. of) a 10 p.c. solution of HCl by adding HgCl₂ (135 g.) dissolved in hot water (1,00 g.). The crystalline double salt is distilled with NaOHAq (Ladenburg, 4. 247, 4).

Properties.—Colourless liquid with powerful odour, miscible with water. Fumes with HCl. Strong poison. Should not be inhaled (Marcus a. Oechsner, Bl. [2] 38, 97; cf. Kendrick a. Dewar, Pr. 22, 432; 23, 290). Forms a hydrate B'Saq. (93°), S.G. 1-0219, V.D. 1-17, which is a colourless liquid (Goldschmidt a. Constam, B. 16, 2976). Not attacked by boiling HNO₃ or CrO₂. Pyridine ppts. the hydroxides of Fe, Al, and Cr from their salts. With CuSO₄ it gives a pale-blue pp. dissolving in excess, forming a deep-blue liquid. Pyridine passes unchanged into the urine (O. de Coninck, Compt. rend. Soc. Biol. 4, 755). Pyridine does not mix with liquid CO₂ (Ditte, C. R. 105, 612). It gives no reaction with hot alkaline NaOBr (Denigès, C. R. 107, 662)

Reactions.—1. Dry chlorine forms di-chloro-pyridine [72°]. Chlorine passed into a solution of pyridine in CHCl, forms B'Cl, a white powder (Bally, B. 21, 1772). Chlorine-water ppts. a white powder. KOCl completely decomposes pyridine, forming N, CO₂, CHCl₃, and chloro-acetic acid (Keiser, Am. 8, 308). -2. Bromine added to a solution of the hydrochloride ppts. C. H. NBr., which is split up by heat into pyridine and bromine. Bromine acting in the cold on pyridine and water gives rise to (C,H,NBr,),HBr [126°] (Grimaux, Bl. [2] 38, 127). Pyridine hydrochloride heated with Br at 200° forms mono- and di-bromo-pyridine.-3. at 200 forms more and alt-promoto-pyrionic—3. HIAq at 300° yields n-pentane and NH, (Hofmann, B. 16, 590).—4. Sodium at 80° yields (γ)-dipyridyl C₁₀H₁N₂, idipyridine C₁₀H₁₀N₂, isonicotine C₁₀H₁N₂, and two nitrogenous oils (240°–250°) and (300°–310°) (Weidel a. Russo, M. 3, 884). - 5. Its alkylo-iodides are converted by distillation with solid KOH into volatile bases .- 6. Excess of AcCl forms dehydracetic acid (Dennstedt a. Zimmermann, B. 19, 75).—7. acid (Dennstedt a. Zimmermann, B. 19, 75).—7. Unites with CH_Cl.OH (the product of the union of formic aldehyde and HCl), and the product in aqueous solution gives with HgCl, a pp. of (C,H,N)(CH,ClOH)HgCl, [162°], with platinic chloride a pp. of (C,H,N),(CH,ClOH),PtCl, [216°], and with picric acid the compound (C,H,N)CH,(OH),C,H,(NO₂),0 [c. 200°]. Treatment with AgNO₂ forms (C,H,N)CH,(OH)NO₂ errystallising from alcoholectic in prisms (Hom. erystallising from alcohol-ether in prisms (Hemmelmayr, M. 12, 533). -8. Alloxan and aqueous SO, form triclinic crystals of B'C, H, N,O, H, SO, (Pellizzari, A. 248, 150).—9. Glycollic chlorhydrin forms the base C₂H₂NO (Coppola, G. 15, 831). Glycerin chlorhydrin reacts with forma-tion of O.H.NCl.C.H. (OH). [107°] separating from alcohol in hexagonal crystals and yielding (C.H., NO, CI), PtCI, [180°] and C.H., NO, CIAuCi, [122°] [Krüger, J. př. [2] 44, 130).—10. Chlorosectic acid at 100° forms C.H., NCI. CH., CO.H.

and B'.CdCl, [107°].
Salts. — B'HCl. Deliquescent mass. B'₂H₂PtCl₆. [242°]. Orange triclinic prisms. The aqueous solution is converted by long boiling into crystalline B',H2Cl2PtCl, and B',PtCl, a yellow insoluble powder .-- B', PtCl, Yellow tables, almost insol. cold water (Jörgensen, J. pr. [2] amost insol. cold water (Jorgensen, J. pr. [2] 33, 504). An isomeride crystallises in needles.

—B',PtCl, 3aq.—B',Pt,Cl,.—B'₂(NH₂),PtCl,.—B'(NH₃)PtCl,.—B'₂(NH₃),PtCl,.—B'(NH₃),PtCl,.—B',(NH₃),PtCl,.—B',(NH₃),PtCl, aq.

colourless prisms.—B',HHg,Cl,. [178°]. Needles (from water).—B'₂3HgCl,.—B',HAuCl,. [285°].

Miscible with

water, forming an acid solution (Gardner, B. 23, 1588).—Formate B'3CH₂O₂. (149°). Liquid, v. sol. water.—Propionate B'3C,H₆O₂. (149°). Liquid. -- Cupric oxalate compound B'CuC.O.: minute prisms (Seubert a. Rauter,

B. 25, 2825).

White Methylo-chloride B'MeCl. needles (Ostermeyer, B. 18, 591). Converted by hot aqueous solution of pieric acid into B'MeOC, H2(NO2)2 2 aq, which crystallises in B'₁Me₂PtO₃, [188] (0.); [207°] (B.). — B'₂Me₂PtO₃, [188°] (0.); [207°] (B.). — B'MeAuCl., [253°].—B'MeClTCl. [82°] (0.); [90°] (B.). Yellow plates.—B'MeClTCl., [180°]. Unstable yellow crystals (Bally, B. 21, 1774).

Methylo-perbromide B'MeBr, [48°]. Methylo-iodide B'MeI. Converted Converted at 290° into methyl-pyridine hydriodides. On heating with alcoholic potash at 45° it yields a brown resin, forming a deep-red solution in alcohol, turned bright-red by HCl, orange-red by acetic acid, and ruby-red by ammonia (O. de Coninck, C. R. 102, 1479). Chlorine forms B'MeICl, [90°] (v. supra). Oxidised by alkaline K₃FeCy, to oxy-methyl-pyridine or v-methyl-pyridone CH CH:CH NMe (250°), a liquid miscible with water (Decker, J. pr. [2] 47, 28; cf. Pechmann, B. 24, 3144).

Ethylo-iodide B'EtI. Silvery tables Anderson, A. 94, 364). At 300° it yields pyridine, NH., (a) and (γ)- ethyl-pyridine, and di-ethyl-pyridine (Ladenburg, B. 16, 2059; 18, 2961). Yields B' Et. PtCl.. Oxidised by alkaline

K₃FeCy₆ to CH≪CH:CO NEt (250°).

Ethyleno-iodide B'C.H.I. Prisms (Coppola, G. 15, 332). Ag.O yields a base C.H.NO. By heating pyridine with ethylene bromide and some alcohol at 100° there is found B'2C2H4Br2, which yields B'2C2H4PtCla (Davidson, A. 121, 254).

Benzylo-chloride B'PhCH,Cl. Reduced by sodium-amalgam to the unstable C21H21N2 (Hofmann, B. 14, 1503).—(B'PhCH,Cl),PtCl,

Nitro-benzylo-chlorides B'C,H,(NO,).CH,Cl. o [c. 76°], m [70°-100], p [90°-100°]. These bodies are reduced by tin and HClAq to B'C,H,(NH,Cl).CH,Cl, which are

Phenacylo-bromide B'BzCII, Br. Prisms (Bamberger, B. 20, 3344).—B'₂(BzCH₂)₂Cr₂O₂.

References.—Bromo-, Chloro-, Oxy-Amido-,

Dipyridine C₀H₁₆N₂ v. DIPYRIDYL DIHYDRIDE.

Dipyridine C₀H₁₆N₂. (275°). S.G. ¹² 1·124.

Is probably a dipyridyl dihydride. Formed by and Oxy. PYRIDINE.

heating nicotine with KOH and K.FeCy, and also by heating the product of the action of S on nicotine at 150° with finely-divided copper (Cahours a. Etard, Bl. [2] 34, 452).
Inactive liquid.—B'HHgCl,—B',HLPtCl, 2aq.—
B',H,FcCy, 2aq: brownish-green tables.

(a) PYRIDINE CARBOXYLIC ACID

C.H.NO. i.e. CH:CH.C.CO.H. Picolinic acid. [136°]. Formed by oxidation of (a)-methylpyridine with KMnO, (Weidel, B. 12, 1994), and by oxidation of (a)-phenyl-pyridine (Skraup, M.

4, 477). Obtained also, together with its herahydride, from comenamic acid by successive treatment with PCl, and H,SO, the resulting di-chloro-picolinic acid being reduced by heating for three days at 155° with HI dissolved in HOAc (Ost, J. pr. [2] 27, 285).

Preparation.—The three acids got by oxida-

tion of crude methyl-pyridine from animal oil are converted into copper salts. Cupric pyridine (a)-carboxylate is extracted by hot water. residue is treated with H.S. and the difficultlysoluble (γ) -acid separated from the (β) -acid (Ost,

J. pr. [2] 27, 286).

Properties .- Needles, v. sol. water and alcohol, almost insol. ether, benzene, CHCl₃, and CS. May be sublimed. FeSO, gives a red colouration with picolinic acid and with all the carboxylic acids of pyridine that contain CO₂H in the (x)-position (Skraup, M. 7, 210). The absorption of the ultra-violet spectrum has been

studied by Hartley (C. J. 41, 45).

Reactions.—1. Yields pyridine on distillation with lime or with alcoholic potash at 240°. The Cu salt on distillation gives pyridine and (a)-dipyridyl [70°] (Blau, M. 10, 375; B. 21, 1077). 2. Sodium-amalgam forms δ-oxy-adipic acid (Weidel, M. 11, 522). 3. Fuming HI at 170° forms (a)-methyl-pyridine and piperidine (Seyfferth, J. pr. [2] 34, 241) .- 4. Zinc-dust and HOAc reduce it to (a)-methyl-pyridine.

Constitution.—This may be deduced from its

formation from (3)-naphthoquinoline via (3)phenyl-pyridine carboxylic acid (Skraup a. Co-

benzl, M. 4, 436).

Salts. - HA'HCl: unstable crystals. H.A',H.PtCl, 2aq: orange-red crystals.—NH,A': triclinic tables.—KA'.—BaA', ½aq.—CaA', aq.— MgΛ', 2aq.

Hexahydride C.H. N.CO.H. Piperidine (a)-carboxylic acid. The chief product of the action of HI at 160° on mono- or di-chloropicolinic acid (Ost, J. pr. [2] 27, 287). Got also by reducing picolinic acid (Ladenburg, B. 24, 640). Syrup, v. sol. water. Salts.—B'HCl. [264°]. Nodules.—B',H,PtCl. [184°] (L.).—B',H,PtCl. 2aq.—B'McCl. [191°]. Needles.

By Hiller (1) archaeolic acid

Pyridine (\$)-carboxylic acid CH:CH.C.CO.H. Nicotinic acid. [230°].

CH: N.CH Formation .- 1. By oxidising nicotine with HNO, (Weidel, A. 165, 330), Cro, (Huber, A. 141, 271; B. 3, 849), or KMnO, (Laiblin, A. 196, 129).—2. A product of oxidation of coal-tar bases (Weidel; Mohler, B. 21, 1003).—3. By heating quinolinic acid at 160° or with HCl at 180° (Ost, J. pr. [2] 27, 286; Lippmann a. Fleissner, M. 8, 315).—4. By oxidation of (β)-methyl-pyridine (Weidel, B. 12, 2004), (β) ethylicidal (Black). pyridine (Stochr, J. pr. [2] 43, 155) or (8)-phenyl-pyridine (Skraup, M. 4, 453).—5. By saponifica-tion of its nitrile, which is got by distilling sodium-pyridine sulphonate with KCy (Fischer, B. 15, 63). - 6. By heating three of the pyridine D. 10, 03).—U. By nearing three of the pyriame dicarboxylic acids (Hoogewerff a. Van Dorp, R. T. C. 1, 1, 107; A. 204, 117; 207, 226; Weidel a. Herzig, M. 1, 16).—7. By heating berberonic acid at 215° (Fürth, M. 2, 420).—8. By the action of Zn and HClAq on chloro-nice.

tinic acid (Pechmann a. Welsh, C. J. 47, 145).

Properties.—Needles, st. sol. cold water, sol. alcohol, nearly insol. ether. May be sublimed.

Reactions.—1. Yields pyridine on distillation with lime.—2. Sodium-amalgam yields a mixture of 8-oxy-a-methyl-glutaric acid and its lactone, which, on treatment with alcohol and HCl, yields a mixture of two ethers. One of these, C₁₀H₁₁ClO₄, is converted by sodium-amalgam into a methyl-glutaric acid, and the other, C₄H₁₄O₄, is also converted by successive treatment with PL₂ and with Zn and dilute H₂SO₄ into a-methyl-glutaric acid (Weidel, M. 11, 502) .-3. Bromine and water at 120° yield CO, pyridine, and bromoform.—4. The K salt heated with MeI at 150° forms C.H.,NMeI.CO,Me, which on saponification yields C.H., NMe(OH).CO.H [130°], converted at 100° into trigonellin C₃H₄NMe<0

[218°], which occurs in the seeds of Trigonella fænum græcum (Jahns, B. 18, 2521; Hantzsch, B. 19, 31). This anhydride forms the salts C,H,NO,HCl, B',H,PtCl, aq, B'HAuCl, [198°], and B',3HAuCl, [186°].

Constitution .- This may be deduced from its formation from (a)-naphthaquinoline vid (a)-

phenyl-pyridine carboxylic acid.

Salts.— HA'HCl. Colourless prisms.— H.A',H.PtCl_a 2aq.—B',H.AuCl₃.—B'HNO₃ aq.— NH,A': needles.—KA'.—MgA'₂: needles.— CaA', 5aq: monoclinic crystals; $a:b:c=1\cdot537:1:\cdot629$; $\beta=62^\circ50^\circ$. — Cu(OH)A' (De Coninck, BL, [2] 42, 100).—AgA': needles (from

Nitrile C,H,N.Cy. [40°]. Formed by distilling sodium pyridine sulphonate with KCy (Fischer, B. 15, 63). Needles or prisms, sol. water.— B'HCl.—B'_H_P(Cl_e: yellow soluble needles. Tables (by sublimation). Converted by means of hydroxylamine into the amidoxim C₃H₁N.C(NH₂):NOH [128°], which yields an acetyl derivative [143°] and a benzoyl derivative [190°], and is converted by phonyl cyanate into $C_*H_*N.C(NOH).NH.CO.NHPh$ [167°], by phonyl thiocarbimide into $C_*H_*N.C < \stackrel{N.S}{N} > C.NHPh$ [241°], and by succinic anhydride at 100° into $C_{*}H_{*}N \stackrel{N.O}{\leqslant} C.CH_{*}CH_{*}.CO_{*}H$ [178°]. acetyl and benzoyl derivatives are converted by heating into $C_3H_4N \stackrel{N.O}{\swarrow} CMe$ [109°] and $C_sH_sN \leqslant_N^{N.O} > CPh$ [139°] respectively (Michaelis, B. 24, 3439).

Hexahydride C, H, N(CO, H). Nipecolinic acid. [250°]. Got by reducing nicotinic acid in alcoholic solution by Na (Ladenburg, B. 25, 2768). Crystals, v. e. sol. water, insol. alcohol and ether.— HA'HCl. [240°].—H_AA'H_aPtCl. [218° cor.].— HA'HAuCl. [197° cor.].— HA'HCl5HgCl_s. [231°].—MeA'HCl [208°].— Me₂A'₄H_aPtCl_s.— Nitrosamine C₆H₁₆N₂O₆. [112°].

Pyridine (γ)-carboxylic acid

N CH.CH C.CO.H. Isonicotinic acid. [805°]

(S.); [806] (B. a. H.); [309-5°] (W. a. H.).

Formation.—1. By heating pyridine s-tricarboxylic acid (Skraup, B. 12, 2331) and three of the pyridine di-carboxylic acids (Hoogewerff a. Van Dorp, A. 204, 112; Weidel a. Herzig, M. 1, 38; Böttinger, B. 15, 68).—2. By the action of KMnO, on (γ)-methyl-pyridine (Behrmann a. Vor. IV. Hofmann, B. 17, 2696; Ladenburg, B. 21, 287). 8. By heating di-chloro-pyridine carboxylic acid [210°] with HI (B. a. H.).

Properties.—Needles, sl. sol. cold water, in-sol. alcohol. Yields pyridine on distilling with lime and 8-oxy-ethyl-succinic acid on reduction with sodium-amalgam (Weidel, M. 11, 517).

Salts.—NH,A': needles.—CaA'₂4aq: silky needles, m. sol. water.—HA'HCl: monoclinio

needles, m. sol. water.—Ha hor. inductions.—H.A',H.PtCl, 2aq: monoclinic crystals.

Hexahydride C₃H₁₀N(CO,H). Got by reducing the zeid in alcoholic solution by Na (Ladenburg, B. 25, 2773). Branching groups of needles, v. e. sol. water, insol. alcohol. Blackens at 300°, but is not melted at 320°.—HA'HCl. [228°]. Trimetric crystals; a:b:c:-922:1: 979.
—HA',H,PtCl_s. [239°]. — Aurochloride; [197°]. Nitrosamine C_sH₁₀N₁O_s. [101°].

Pyridine (ac)-dicerboxylic acid

CH CH.C(CO.H) N. Dipicolinic acid. [226°] (L. a. R.; S.); [237°] (E.); [236° cor.] (Collie, C. J. 59, 179). Formed by oxidation of (aa)-dimethyl-pyridine [145°] (derived from acetoacetic ether or from coal-tar) by KMnO, (Epstein, A. 231, 26; Ladenburg a. Roth, B. 18, 52; 19, 790; 20, 130; A. 247, 32; Lange a. Rosenberg, B. 20, 132; cf. Dewar, C. N. 23, 18). Got also by oxidation of (α)-methyl-(α)-ethyl-pyridine by dilute (2 p.c.) KMnO, (Schultz, B. 20, 2724).

Properties .- Hair-like needles (containing 1 aq) or anhydrous scales; sl. sol. cold alcohol, water, and ether. On heating at 245° in a curwater, and etner. On neuting at 225 in a current of H it yields pyridine and pyridine (a)-carboxylic acid. PCl, forms a chloride [61°], (284°). FeSO, gives a reddish-yellow colour. Salts. — CAA" 2aq: minute prisms. —

CuA" 2aq : dark-blue prisms.

Pyridine (aB)-dicarboxylic acid

C(CO,H).C(CO,H) N. Quinolinic acid. [281°]. S. .55 at 6.5°. Formed by the oxidising action of KMnO, on quinoline (Hoogewerff a. van Dorp, B. 12, 747; R. T. C. 1, 107; A. 204, 117), on cinchonine (H. a. D.), on o and p methylquinoline (Skraup, M. 2, 157), on o oxyquinoline, on quinoline o-sulphonic acid (O. Fischer a. Renouf, B. 17, 755), and on (α)-oxy-quinoline carboxylic acid (La Coste a. Valeur, B. 20, 103).

Properties. - Monoclinic needles, a:b:c = .542:1: .607; $\beta = 64° .54'$; sl. sol. water and alcohol, insol. ether. Begins to decompose at 140°, and forms nicotinic acid. Yields pyridine when distilled with limo. Reduced by sodium-amalgam to the δ-lactone of butane aβγ-tricarboxylic acid CH., CH., CH.CO., H (Perimutter, M. 13, 840).

Salts.—KHA" 2aq: triclinic plates (Lippmann a. Fleissner, M. 8, 311).—K_AA" 2aq.—BaA" aq.—Ag,A": crystalline.—AgHA" aq.

Anhydride C.H.N CO O. [185°]. Got from the acid and Ac₂O (Bernthsen a. Mettegang, B. 20, 1208). Prisms. Converted by benzene and AlCl₂ into C₂H₄BzN.CO₂H [147°], converted by heat into the ketone C₃H₄BzN (307° uncor.), which yields a crystalline phenyl-

hydrazide [143.5°].

Pyridine (a7) dicarboxylic acid

CO₂H.O CH:C(CO₂H) N. Luti Lutidinic acid.

[240°] (V.); [235°] (B.; L. a. R.). Formed by the oxidising action of KMnO, on (ay)-dimethyl-pyridine (Ramsay, P. M. [5] 4, 241; 6, 19; Weidel a. Herzig, M. 1, 20; Ladenburg a. Roth, B. 18, 915; A. 247, 37), on (a)-methyl-cy)-ethyl-pyridine (Schultz, B. 20, 2726), on distribution of the distribution of the control o ethyl-pyridine, on (aa)-di-methyl-dipyridyl (Heuser a. Stochr, J. pr. [2] 44, 409), and on the methyl-pyridine carboxylic acid obtained from uvitonic acid (Böttinger, B. 14, 68; 17, 93; Voigt,

Properties.—Needles (containing aq), m. sol. cold water, sol. alcohol, insol. ether. Gives a blood-red colour with FeSO. Yields pyridine on distillation with lime. Converted by heat into CO2 and isonicotinic acid. PCl, yields a

chloride [203°]

Salts.-KHA" jaq. Crystals.-(NH4)2A".-CuA" 4aq (B.).—Ag₂A" 2aq: white pp.

Pyridine (ab')-dicarboxylic acid

CH\(C(CO_2H).CH\) N. Isocinchomeronic acid.

Formation.-1. By oxidation of lutidine rormation.—1. By oxidation of intidine (150°-170°) with KmO, (Ramsay, P. M. [5] 4, 246; Weidel a. Herzig, M. 1, 1; Lange a. Rosenberg, B. 20, 135).—2. By oxidising (B)—methyl-(a)-ethyl-pyridine (Ladenburg, A. 247, 44).—8. By oxidation of quinine (Ramsay a. Dobble, C. J. 33, 102; B. 11, 324).—4. By heating the dishydride of profession purisions treath ing the dihydride of potassium pyridine tricarboxylate (Weiss, B. 19, 1311).-5. By the action of alkaline KMnO, on cyclothraustic acid and on pyridanthrilic acid (Weidel a. Strache, M. 7, 290). - 6. By oxidising (β)-ethyl-(α)-stilbazole (Plath, B. 22, 1062).

Properties .- Small prisms (containing aq), almost insol. cold water, alcohol, and benzene, sol. hot HClAq. On heating with HOAc at 220° it is split up into CO, and nicotinic acid [230° On heating with lime it gives pyridine. PCl. yields a chloride [61°] converted by NH, into an amide [297°]. FeSO, gives a reddish colour.

colour.

Salts.—(NH₁)HA" aq. [253°]. Triolinic prisms, sl. sol. cold water.—(NH₁)₂A".—
KHA" aq: needles.—K₁A" aq.—CaA" 2aq.—
Ca(HA"), 3aq.—MgA" 5aq.—CuA" aq.—Ag.A".

Methyl ether Me.A". [117:5°] (R.).

Pyridine (8B')-dicarboxylic acid

CH ⟨C(CO,H).CH⟩N. Dinicotinic acid. [822°]. Formed by heating pyridine (2,3,5)-tri-carboxylic acid and pyridine (2,3,5,6)-tetra-carboxylic acid (Riedel, B. 16, 1613; Hantzsch a. Weiss, B. 19, 286; Weber, A. 241, 12). Formed also by heating di-chloro-pyridine di-carboxylic acid with conc. HIAq at 180° (Guthzeit, A. 262, 130).

Properties.—Small prisms (from HOAc), split up by heat into CO₂ and nicotinic acid.

Salts.—PbA" 2aq.—Ag.A" aq.—Ag.A" 1½aq.

-HA'HCl 2aq: needles, decomposed by water.

-H.A',H.PtCl_s: orange-red needles.
Pyrldine (β_{γ}) -dicarboxylic acid

CO,H.C $\stackrel{C(CO_2H):CH}{CH}$ N. Cin Cinchomeronic

acid. [259°].

Formation.-1. By oxidation of cinchonine or cinchonidine by HNO, of S.G. 1.4 (Weidel, A. 173, 76). -2. By oxidation of quinine by HNO, the yield being 28 p.c. (Weidel a. Schmidt, B. 12, 1146).—3. By heating apophyllenic acid with conc. HClAq at 240° (Von Gerichten, B. 13, 1635). - 4. By heating pyridine tricarboxylic acid (formed from cinchonic acid) at 190° (Hoogewerff a. van Dorp, B. 13, 61; Skraup, M. 1, 184; Weidel a. Brix, M. 3, 604) .- 5. By the action of KMnO, on methyl-pyridine carboxylic acid and on isoquinoline (Hoogewerff a. van Dorp, R. T. C. 2, 23; 4, 285,—6. By heating pyridine pentacarboxylic acid (Weber, A. 241, 16).—7. By oxidation of methyl-nicotinic acid, derived from (B)-collidine (Oechsner de Coninck, Bl. [2] 43, 106). -8. By boiling berberonic acid with HOAc (2 pts.) and Ac.O (1 pt.) for six hours (Mayer, M. 13, 344; cf. Fürth, M. 2, 426).

Properties.—Prisms (from HClAq), v. sl. sol. water and ether, sl. sol. alcohol. Yields isonicotinic and some nicotinic acid on heating (Hoogewerff a. van Dorp, A. 207, 217). Gives pyridine on distillation with lime. Sodiumamalgam yields NH, and cinchonic acid C,H,O, i.e. $CO_2H.CH < CH_2.CO_2 > 0$ (Weidel a. Hoff, M.

CO.H

13, 578). Cinchonic acid [169°] forms monoclinic crystals, v. sol. hot water and alcohol, and yields BaC,H₀O₆ 3aq, Ba₃(C,H₁O₇)₂ 3aq, CaA'' 2aq, Ca₃(C,H₁O₇)₂ (dried at 190), and oily Et₄A'', whence PCl₃, followed by alcohol, yields CO₂Et.CH(CH₂Cl).CH(CO₂Et).CH₂CO₂Et, which is a heavy oil. Cinchonic acid is reduced by HI to butane tricarboxylic acid C, H10O6 [184°], whence Ca, A", 8aq, accompanied by an isomeric butane tricarboxylic acid [133°]. FeSO, gives no colour.

Salts .- Na, A" 2aq: tables.-NaHA".-BAITS.—Na₂A 2aq: BOIES.—NAITA', — RAA'' 1₃aq: needles, sl. sol. water.—CaA'' 3₃aq: prisms. — CaA'' 3aq. — CuA'' 3₃aq: small blue crystals.—Ag₂A'': white pp.—AgHA''.— HA'HCl: monoclinic prisms, decomposed by

water.—H.A'₂H.PtCl₃: golden prisms.

Anhydride (C,H₂N).C.O₃. [77°]. Formed by boiling the acid with Ac₂O (Goldschmiedt a. Strache, M. 10, 156). Plates. May be sublimed. Converted by NH, gas into C,H,N(CO,NH,).CONH, [229°], which is converted by heat into a yellow powder [130°], and which yields the amic acid C₄H₄N(CO₂H).CONH₂ [237°], orystallising in needles.

Mono-ethyl ether HEtA". [133°]. Formed from the anhydride and EtOH. Plates (from benzene).-AgEtA": long needles.

Mono-methyl ether HMeA". [154°]. Anhydride of the Methylo-hydroxide C₃H,NO₄ i.e. C₄H₂NMc(CO₂H) CO Apophyllenic acid [242°]. Formed by oxidation of cotarnine by HNO, (Wöhler, A. 50, 24; Anderson, Tr. E. 23, 347; C. J. 5, 257; Gerichten, B. 13, 1635). Formed also by heating cinchomeronic acid with MeI and MeOH at 100° (Roser, A. 234, 116). Needles (anhydrous) or octahedra (containing aq), sol. hot water, insol. alcohol and ether. HClAq at 250° decomposes it, forming cinchomeronic acid and McCl. — BaA'. AgA'.-Ag,A'(NO,).-H,A',H,PtCl, aq.

Bromo-spophyllenic acid C.H.BrNO, 2aq. [205]. Formed by oxidation of bromo-tarconine. Yields BaA', 3aq and H2A'2H.PtCl. (Gerichten, A. 210, 91).

Pyridine (aa'8)-tricarboxylic acid

CH < C(CO,H), C(CO,H) > N. Formed by oxidising di-methyl-nicotinic acid with KMnO, (Weiss, B. 19, 1309). Crystallises from alcohol in plates B. 19, 1909). Crystamses from arcono in places (containing 2aq), v. e. sol. water. Decomposes at 160° into CO₂ and isocinchomeronic acid. FcSO₄ colours its neutral solution red.—

KII₄A''', 5aq: needles.—Ca,A''', 4aq.—Pb₃A'''₂ 5aq. Pyridine (aa'\gamma)-tricarboxylic acid

 $CO_zH.C \stackrel{CH.C(CO_zH)}{\leqslant} N.$ Trimesitic acid. Carbolutidinic acid. [244°]. Formed by oxidation of uvitonic acid (Böttinger, B. 13, 2048; 14, 69), and by oxidation of the tri-methyl-pyridine obtained from acetoacetic ether and aldehyde-ammonia (Voigt, A. 228, 31). Tables or spheroidal groups of needles (containing 2aq), sol. hot water, sl. sol. alcohol and ether. Yields isonicotinic acid on sublimation. FeSO, gives a violet-red colour.

For each colour. So alts.— $K_1A'''_5aq$: needles.— $Ca_2A'''_24aq$.—Ba, A'''_26aq .—Ba $H_1A'''_24aq$.— $Mg_2A'''_212aq$.— $Cu_2A'''_212aq$.— $Ag_3A'''_14aq$.

Ethylether Et,A'''. [127-5°].

Amide. [above 280°].

Pyridine (aBB') tri-carboxylic acid

CH C(CO,H):C(CO,H) N. Carbodinicotinic acid. [323°]. Formed by oxidation of quinoline (Py. 2)-carboxylic acid (Riedel, B. 16, 1615), methyl-pyridine (BB)-dicarboxylic (Weber, A. 241, 11), and of the parvoline got by heating propionic aldehyde ammonia with propionic aldehyde at 200° (Dürkopf, B. 21, 832, 2707; 23, 689). Spherical aggregates (containing 1 aq), v. sol. hot water. At 155° it is split up into CO, and dinicotinic acid,—Ba,A''', 5aq, -- Ag, HA''' 1 aq : rosettes of plates. Pyridine (αβγ)-tri-carboxylic acid

 $CO_2H.C \leqslant \begin{array}{c} C(CO_2H):C(CO_2H) \\ CH \end{array} > N. \quad [250^\circ] \text{ (H. 8.}$ D.; S.); [257°] (D. a. R.). S. 1.2 at 15°.

Formation. -1. By the action of KMnO, on quinine, cinchonine, cinchonidine, quinoïdine, and einchonic acid (Dobbie a. Ramsay, C. J. 35, 189; Hoogewerff a. van Dorp, B. 12, 158; 13, 152; A. 201, 84; Skraup, A. 201, 312; Strache, M. 10, 642).—2. By oxidation of cinchonine by HNO, (Weidel, A. 173, 101; B. 12, 415).—3. By oxidation of methyl-pyridine (αβ)-dicarboxylic acid (Hoogewerff a. van Dorp, R. T. C. 2, 18), of di-methyl-pyridine carboxylic acid (Michael, B. 18, 2027), of (a)-oxy-cinchonic acid (Weidel a. Cobenzl, M. 1, 865).—4. By oxidation of papaverine (Goldschmiedt, M. 6, 397). Trimetric plates (containing 1 aq), v. sol. hot water, m. sol. alcohol, nearly insol. ether. Blackens at 200°. FeSO, gives a reddish colour. H2S forms by long heating at 180°, or by boiling with HOAc into CO₂ and cinchomeronic acid. Yields pyridine on distilling with lime. MeI and MeOH at 100° form CO, and apophyllenic acid. Sodium-amalgam gives NH, and cinchonic acid. PCl, forms a chloride (206° at 40 mm.). Salts. — K₁A'''3aq. — Ba₂A''', 16aq. —

Pyridine $(a\beta'\gamma)$ -tricarboxylic acid $CO_{\cdot}H.C \stackrel{CH.C(CO_{\cdot}H)}{<}N.$ Berberonic acid. [243°]. Formed by oxidising berberine with nitric acid (Weidel, B. 12, 410; Fürth, M. 2, 416). Triclinic prisms (containing 2nq), sol. hot water, v. sl. sol. hot alcohol, insol. ether. Yields pyridine on distillation with lime. FeSO, gives a red colour. At 215° it is split up into CO. and nicotinic acid; above 243° it yields isonicotinic acid.

Salts. — K₃A" 4\aq. — K₂HA" 8aq. — KH₂A" 1\quad qq. — Cd₃A" 2\aq. — Cd₃A" 4aq. — Ag,A": white pp., insol. water.

Pyridine (\$\beta B'. 9) tricarboxylic acid

CO₂H.C $\stackrel{C}{<}$ C(CO₂H).CH $\stackrel{N}{>}$ N. (8) - Carbocinchomeronic acid. [261°]. Formed by heating dipotassium pyridine pentacarboxylate at 220° (Weber, A. 241, 17). Plates (containing 3aq), v. sol. hot water. Yields cinchomeronic acid when heated. Gives no colour with FeSO. - Cu,11,4", 24aq. -- Ag,4"' 2aq: crystalline pp.

Pyridine $(a\beta\beta'\gamma)$ -tetra-carboxylic acid

 $C_0H_0NO_0$ i.e. $CO_2H_0C < C(CO_2H_0) < C(CO_2H_0) > N$. Formed by oxidising $(\alpha \gamma)$ -di-methyl-pyridine $(\beta \beta')$ -dicarboxylic acid (Weber, A. 241, 23). Prisms (containing 2aq or 3aq). At 120° it loses CO, forming (B)-carbocinchomeronic acid. FeSO, gives a dark-red colour. - Ba, Aiv 4aq. -

Ag, ΠΛ¹ν, nq: crystalline.

Pyridine (αα'ββ')-tetracarboxylic acid
CII C(CO, H).C(CO, H)
C(CO, H):C(CO, H)
N. Formed by oxidisdicarboxylic di-methyl-pyridine (Hantzsch, B. 19, 286; Weber, A. 241, 4). Needles (containing 2aq), v. sol. water. Decomposes at 150° into CO2 and dinicotinic acid .-CaH_Aiv 2aq: needles, v. sol. water.—Cu,Aiv 5aq. - Ag, Aiv 2aq : bulky pp.

Pyridine $(\alpha\alpha'\beta'\gamma)$ -tetra-carboxylic acid $CO_{\cdot}H.C \ll_{C(CO_{\cdot}H)\cdot C(CO_{\cdot}H)}^{CII} \gg N$. Formed by oxidation of tri-methyl-pyridine carboxylic acid and of di-methyl-pyridine di-carboxylic acid (Michael, A. 225, 142). Formed also by oxidation of flaveriol by alkaline KMnO, (Fischer a. Täuber, B. 17, 2927). Slender needles (containing 2aq), v. sol. water, v. sl. sol. alcohol and ether. Not decomposed at 150°. FeSO gives a brownish-red colour. - Ba, Aiv 2 aq. - Ba, Aiv aq. -Cu₂A" 2½aq. - Ag,Alv aq.

Pyridine penta-carboxylic acid NC (CO.H), Formed from potassium tri-methyl-pyridine dicarboxylate and KMnO, (Hantzsch, A. 215, 62; Weber, A. 241, 15). Crystalline mass of minute needles (containing 2aq), extremely sol. water, v. sl. sol. ether. Acid to litmus and to taste. Loses 2aq at 120° and decomposes, without having melted, at 220°. The neutral alkaline salts are very soluble, but the acid alkaline salts are sl. sol. water. The acid does not combine with HCl. Distilled with lime it gives pyridine. FeSO, gives a dark-red colour.

water, forming an acid solution (Gardner, B. 23, 1588).—Formate B'3CH₂O_x. (149°). Liquid, v. sol. water.—Propionate B'3C_xH₂O_x. (149°). Liquid. — Cupric oxalate compound B'₂CuC₂O₄: minute prisms (Seubert a. Rauter, B. 25, 2825).

Methylo-chloride B'MeCl. needles (Ostermeyer, B. 18, 591). Converted by a hot aqueous solution of picric acid into B'MeOC₆H₂(NO₂)₃ ¹/₂aq, which crystallises in greenish-yellow explosive needles [34°]. — B'2Me,PtCl₄. [188°] (O.); [207°] (B.). — B'MeAuCl₄. [253°].—B'MeCllCl. [82°] (O.); B'MeAuCl., [253°].—B'MeClICl. [82°] [0.], [90°] (B.). Yellow plates. B'MeClICl., [180°]. Unstable yellow crystals (Bally, B. 21, 1774).

Methylo-perbromide B'MeBr. [48°

Methylo-iodide B'MeI. Converted at 290° into methyl-pyridine hydriodides. On heating with alcoholic potash at 45° it yields a brown resin, forming a deep-red solution in alcohol, turned bright-red by HCl, orange-red by acetic acid, and ruby-red by ammonia (O. de Coninck, C. R. 102, 1479). Chlorine forms B'MeICl₂ [90°] (v. supra). Oxidised by alkaline K₃FeCy₈ to oxy-methyl-pyridine or v-methyl-pyridone CH CH.CO NMe (250°), a liquid miscible with water (Decker, J. pr. [2] 47, 28; cf. Pechmann, B. 24, 3144).

Ethylo-iodide B'EtI. Silvery tables Anderson, A. 94, 364). At 300° it yields pyridine, NH₃, (a) and (\gamma)- ethyl-pyridine, and diethyl-pyridine (Ladenburg, B. 16, 2059; 18, 2961). Yields B' Et. Pt. Co. Oxidised by alkaline

K,FeCy, to CH CH:CH NEt (250°).

Ethyleno-iodide B'C.H.I. Prisms (Coppola, G. 15, 332). Ag.O yields a base C.H.NO. By heating pyridine with ethylene bromide and some alcohol at 100° there is found B',C,H,Br., which yields B',C,H,PtCl, (Davidson, A. 121, 254).

Benzylo-chloride B'PhCH,Cl. Reduced by sodium-amalgam to the unstable C21H21N2 (Hofmann, B. 14, 1503) .- (B'PhCH2Cl)2PtCl4.

Nitro benzylo-chlorides
B'O.H.(NO₂).OH₂Cl. o [0.76°], m [70°-100°], p
[90°-100°]. These bodies are reduced by tin and HClAq to B'C,H,(NH,Cl).CH,Cl, which are split up by heat into pyridine hydrochloride and C₄H₄ < NH₂Cl (Lellmann a. Pekrun, A. 259, 54).

Phenacylo-bromide B'BzCH2Br. Prisms (Bamberger, B. 20, 3344).— $B'_2(BzCH_2)_2Cr_2O_7$.

References .- BROMO-, CHLORO-, OXY-AMIDO-, and Oxy- PYRIDINE.

Dipyridine $C_{10}H_{10}N_2$ v. Dipyridyle dihydride. Dipyridine $C_{10}H_{10}N_2$. (275°). S.G. 13 1·124. Is probably a dipyridyl dihydride. Formed by heating nicotine with KOH and K.FeCy, and also by heating the product of the action of S on nicotine at 150° with finely-divided copper (Cahours a. Etard, Bl. [2] 34, 452). Inactive liquid.—B'HHgCl,.—B',H.PtCl, 2aq.—

B',H,FeCy,2aq: brownish-green tables.
(a)-PYRIDINE CARBOXYLIC ACID

C_eH_bNO₂ i.e. CH:CH.C.CO₂H Picolinic acid. [186°]. Formed by oxidation of (a)-methyl-pyridine with KMnO, (Weidel, B. 12, 1994), and by oxidation of (a)-phenyl-pyridine (Skraup, M.

4, 477). Obtained also, together with its hexa-hydride, from comenamic acid by successive treatment with PCl₂ and H₂SO₄, the resulting di-chloro-picolinic acid being reduced by heating HOAc (Ost, J. pr. [2] 27, 285).

Preparation.—The three acids got by oxida-

tion of crude methyl-pyridine from animal oil are converted into copper salts. Cupric pyridine (a)-carboxylate is extracted by hot water. The residue is treated with H.S. and the difficultlysoluble (y)- acid separated from the (\$\textit{\textit{g}}\)- acid (Ost, J. pr. [2] 27, 286).

Properties.—Needles, v. sol. water and alco-

hol, almost insol. ether, benzene, CHCl₃, and CS₂. May be sublimed. FeSO₄ gives a red colouration with picolinic acid and with all the carboxylic acids of pyridine that contain CO_2H in the (2)-position (Skraup, M. 7, 210). The absorption of the ultra-violet spectrum has been

studied by Hartley (C. J. 41, 45).

Reactions.—1. Yields pyridine on distillation with lime or with alcoholic potash at 240°. The Cu salt on distillation gives pyridine and (α)dipyridyl [70°] (Blau, M. 10, 375; B. 21, 1077). 2. Sodium-amalgam forms δ-oxy-adipic acid (Weidel, M. 11, 522). -3. Fuming HI at 170° forms (a)-methyl-pyridine and piperidine (Seyfferth, J. pr. [2] 34, 241).—4. Zinc-dust and HOAc reduce it to (a)-methyl-pyridine.

Constitution.—This may be deduced from its

formation from (β)-naphthoquinoline via (β)phenyl-pyridine carboxylic acid (Skraup a. Co-

benzl, \hat{M} . 4, 436).

Salts. - HA'HCl: unstable crystals. -H₂A'₂H₂PtCl₆ 2aq: orange-red crystals.—NH₄A': triclinic tables.—KA'.—BaA'₂ ½aq.—CaA'₂ aq.—

MgA'2 2aq.

Hexahydride C₅H₁₀N.CO₂H. Piperidine (a)-carboxylic acid. The chief product of the action of HI at 160° on mono- or di-chloropicolinic acid (Ost, J. pr. [2] 27, 287). Got also by reducing picolinic acid (Ladenburg, B. 24, 640). Syrup, v. sol. water. Salts.—B'HCl. [264°]. Nodules.—B'₂H₄PtCl₆. [184°] (L.).—B'₂H₄PtCl₆ 2aq.—B'MeCl. [191°]. Needles.

Pyridine (B)-carboxylic acid CH.CH.C.CO.H. Nicotinic acid. [230°].

Formation .- 1. By oxidising nicotine with HNO, (Weidel, A. 165, 330), CrO, (Huber, A. 141, 271; B. 3, 849), or KMnO. (Laiblin, A. 196, 129).—2. A product of oxidation of coal-tar bases (Weidel; Mohler, B. 21, 1009).—3. By heating quinolinic acid at 160° or with HCl at 180° (Ost, J. pr. [2] 27, 286; Lippmann a. Fleissner, M. 8, 315).—4. By oxidation of (β) methyl-pyridine (Weidel, B. 12, 2004), (B)-ethylpyridine (Stoehr, J. pr. [2] 43, 155) or (β)-phenylpyridine (Skraup, M. 4, 453).—5. By saponification of its nitrile, which is got by distilling sodium-pyridine sulphonate with KCy (Fischer, B. 15, 63). -6. By heating three of the pyridine dicarboxylic acids (Hoogewerff a. Van Dorp, R. T. C. 1, 1, 107; A. 204, 117; 207, 226; Weidel a. Herzig, M. 1, 16).—7. By heating berberonic acid at 215° (Fürth, M. 2, 420).—8. By the action of Zn and HClAq on chloro-nico-tinic acid (Pechmann a. Welsh, C. J. 47, 145).

Properties. - Needles, sl. sol. cold water, sol. alcohol, nearly insol. ether. May be sublimed.

Reactions.—1. Yields pyridine on distillation with lime.—2. Sodium-amalgam yields a mixture of 8-oxy-a-methyl-glutaric acid and its lactone, which, on treatment with alcohol and HCl. yields a mixture of two ethers. One of these, C10H17ClO4, is converted by sodium-amalgam into a-methyl-glutaric acid, and the other, C_sH_{1,1}O₄, is also converted by successive treat-ment with PI₂ and with Zn and dilute H₂SO₄ into a-methyl-glutaric acid (Weidel, M. 11, 502).-8. Bromine and water at 120° yield CO₂, pyridine, and bromoform.—4. The K salt heated with MeI at 150° forms C.H.NMeI.CO.Me. which on saponification yields C.H.NMe(OH).CO.H [130°], converted at 100° into trigonellin C₅H₄NMe<

[218°], which occurs in the seeds of Trigonella fænum græcum (Jahns, B. 18, 2521; Hantzsch, B. 19, 31). This anhydride forms the salts C,H,NO,HCl, B',H,PtCl, aq, B'HAuCl, [198°], and B',3HAuCl, [186°].

Constitution.—This may be deduced from its formation from (a)-naphthaquinoline vid (a)-

phenyl-pyridine carboxylic acid.

Salts. - HA'HCl. Colourless Saits.—HA'HO!. Colourless prisms.— $H_2A'_2H_2PtCl_0$ 2aq.— $B'_2H_2AuCl_3$.— $B'HNO_3$ aq.— NH_A' : needles.—KA'.— MgA'_2 : needles.— CaA'_2 5aq: monoclinic crystals; a:b:c=1:537:1::629; $\beta=62^\circ$ 50'.—Cu(OH)A' (De Coninck, Bl. [2] 42, 100) .- AgA': needles (from hot water).

Nitrile C,H,N.Cy. [49°]. Formed by distilling sodium pyridine sulphonate with KCy (Fischer, B. 15, 63). Needles or prisms, sol. water. — B'HCl. — B'₂H₂PtCl₆: yellow soluble needles. Tables (by sublimation). Converted by means of hydroxylamine into the amidoxim C₃H₁N.C(NH₂):NOH [128°], which yields an acetyl derivative [143°] and a benzoyl derivative [190°], and is converted by phenyl cyanate into C_bH₄N.C(NOH).NH.CO.NHPh [167°], by phenyl thiocarbimide into $C_sH_sN.C \leqslant N \lesssim C.NHPh$ $C_{a}H_{a}N \leqslant_{N}^{N.O} \geqslant CPh$ [139°] respectively chaelis, B. 24, 3439).

Hexahydride C, H, N(CO, H). Nipecotinic acid. [250°]. Got by reducing nicotinic acid in alcoholic solution by Na (Ladenburg, B. 25, 2768). Crystals, v. e. sol. water, insol. alcohol 2706). Crystais, v. e. soi. Water, insoi. alcohol and ether.—HA'HCl. [240°].—H_A',H_2PtCl., [213° cor.].— HA'HCl5HgCl., [231°].—MeA'HCl [208°].— Me,A',H,PtCl., — Nitrosamine C.,H₁₈N₂O₃. [112°].

Pyridine (γ) -carboxylic acid

N CH.CH C.CO.H. Isonicotinic acid. [305°]

(S.); [306] (B. a. H.); [309-5°] (W. a. H.). Formation.—1. By heating pyridine s-tri-carboxylic acid (Skraup, B. 12, 2331) and three of the pyridine di-carboxylic acids (Hoogewerff a. Van Dorp, A. 204, 112; Weidel a. Herzig, M. 1, 28; Böttinger, B. 14, 68).—2. By the action of KMnO, on (γ)-methyl-pyridine (Behrmann a. Vol. IV. Hofmann, B. 17, 2696; Ladenburg, B. 21, 287). 8. By heating di-chloro-pyridine carboxylic acid

[210] with HI (B. a. H.).

Properties.—Needles, sl. sol. cold water, insol. alcohol. Yields pyridine on distilling with lime and 8-oxy-ethyl-succinic acid on reduction with sodium-amalgam (Weidel, M. 11, 517).

Salts.-NH,A': needles.-CaA', 4aq: silky needles, m. sol. water .- HA'HCl: monoclinic prisms.—H₂A'₂H₂PtCl₆ 2aq: monoclinic crystals.

Hexahydride C,H,ON(CO,H). Got by reducing the acid in alcoholic solution by Na (Ladenburg, B. 25, 2773). Branching groups of needles, v. e. sol. water, insol. alcohol. Blackens at 300°, but is not melted at 320°.—HA'HCl. [228°]. Trimetric crystals; a:b:c = 922:1: 979. [228]. Trimetric crystals; a.b.c - 922:1: 979.

-H.A'₂H₂PtCl_e. [239°]. — Aurochloride:
[197°]. Nitrosamine C₆H₁₉N₂O₃. [101°].

Pyridine (ac)-dicarboxylic acid

CH CH.C(CO.H) N. Dipicolinic acid. [226°]

CH.C(CO.H) N. Dipicolinic acid. [226°] (L. a. R.; S.); [237°] (E.); [236° cor.] (Collie, C. J. 59, 179). Formed by oxidation of (ac)-dimethyl-pyridine [145°] (derived from acetoacetic ether or from coal-tar) by KMnO, (Epstein, A. 231, 26; Ladenburg a. Roth, B. 18, 52; 19, 790; 20, 130; A. 247, 32; Lange a. Rosenberg, B. 20, 132; cf. Dewar, C. N. 23, 18). Got also by oxidation of (a) methyl-(a)-ethyl-pyridine by dilute (2 p.c.) KMnO, (Schultz, B. 20, 2724). Properties.—Hair-like needles (containing

1 aq) or anhydrous scales; sl. sol. cold alcohol. water, and ether. On heating at 245° in a current of H it yields pyridine and pyridine (a)-carboxylic acid. PCl_s forms a chloride [61°], (284°). FeSO, gives a reddish yellow colour.

Salts. - CaA" 2aq: minute prisms. -CuA" 2aq: dark-blue prisms.

Pyridire (aB) dicarboxylic acid

C(CO₂H).C(CO₂H) N. Quinolinic acid. [231°]. S. .55 at 6.5°. Formed by the oxidising action of KMnO, on quinoline (Hoogewerff a. van Dorp, B. 12, 747; R. T. C. 1, 107; A. 204, 117), on cinchonine (H. a. D.), on o- and p- methyl-quinoline (Skraup, M. 2, 157), on o-oxy-quinoline, on quinoline o-sulphonic acid (O. Fischer a. Renouf, B. 17, 755), and on (α)-oxy-quinoline carboxylic acid (La Coste a. Valeur, B. 20, 103).

Properties. — Monoclinic needles, a:b:c=542:1:607; $\beta=64°54'$; sl. sol. water and alcohol, insol. ether. Begins to decompose at 140°, and forms nicotinic acid. Yields pyridine when distilled with lime. Reduced by sodium-amalgam to the δ-lactone of butane aβγ-tricarboxylic acid CH. CH. CH. CO. H (Perlmutter, M. 13, 840).

Salts.—KHA" 2aq: triclinic plates (Lippmann a. Fleissner, M. 8, 311).—K₂A" 2aq.— BaA" aq.—Ag2A": crystalline.—AgHA" aq.

Anhydride C,H,N $<_{CO}^{CO}>0$. [135°]. Got from the acid and Ac₂O (Bernthsen a. Mettegang, B. 20, 1208). Prism... Converted by benzene and AlCl, into C₂H₂BzN.CO₂H [147°], converted by heat into the ketone C₂H₃BzN (307° uncor.), which yields a crystalline phenylhydrazide [143·5°].
Pyridine (a_γ)-dicarboxylic acid

CO'H'C CH CHO'H) N' Lutidinic acid.

A A

[240°] (V.); [285°] (B.; L. a. R.). Formed by the oxidising action of KMnO, on (eq)-dimethyl-pyridine (Ramsay, P. M. [5] 4, 241; 6, 19; Weidel a. Herzig, M. 1, 20; Ladenburg a. Roth, B. 18, 915; A. 247, 87), on (a)-methyl-(γ)-ethyl-pyridine (Schultz, B. 20, 2726), on di-ethyl-pyridine, on (αα)-di-methyl-dipyridyl (Heuser a. Stochr, J. pr. [2] 44, 409), and on the methyl-pyridine carboxylic acid obtained from nvitonic acid (Böttinger, B. 14, 68; 17, 93; Voigt, A. 228, 54).

Properties.—Needles (containing aq), m. sol. cold water, sol. alcohol, insol. ether. Gives a blood-red colour with FeSO. Yields pyridine. on distillation with lime. Converted by heat into CO2 and isonicotinic acid. PCl, yields a

chloride [203°]

Salts.-KHA" aq. Crystals.-(NH4)2A".-Salts.—KHA" kaq. Crystals.—(NH₄)A".—(NH₄)HA" aq: hygroscopic needles.—CaA" 3aq. CaA" aq.—CaA" &q.—CaA" &q.—BaA" aq.—BaA" aq.—BaA" aq.—BaA" aq.—BaA" aq.—BaA" aq.—BaA" aq.—CuA" aq. (Waage, M. 4, 727).—MgA" 5aq.—CuA" 3aq.—CuA" 4aq (B.).—Ag.A" 2aq: white pp. Pyridine (ab')-dicarboxylic acid. CH<CH:C(CO₂H)>N. Isocinchomeronic acid.

Formation.—1. By oxidation of lutidine (150°-170°) with KMnO₄ (Ramsay, P. M. [5] 4, 246; Weidel a. Herzig, M. 1, 1; Lange a. Rosenberg, B. 20, 135).—2. By oxidising (B')-methyl-(a)-ethyl-pyridine (Ladenburg, A. 247, 13) with the state of the control of the co 44).—3. By oxidation of quinine (Ramsay a. Dobbie, C. J. 33, 102; B. 11, 324).—4. By heating the dihydride of potassium pyridine tricarboxylate (Weiss, B. 19, 1311).—5. By the action of alkaline KMnO, on cyclothraustic acid and on pyridanthrilic acid (Weidel a. Strache, M. 7, 290). - 6. By oxidising (β)-ethyl-(α)-stilbazole (Plath, B. 22, 1062).

Properties .- Small prisms (containing aq), almost insol. cold water, alcohol, and benzene, sol. hot HClAq. On heating with HOAc at 220° it is split up into CO, and nicotinic acid [230°]. On heating with lime it gives pyridine. PCl. yields a chloride [61°] converted by NII, into an amide [297°]. FeSO₄ gives a reddish

colour.

Colour.

Methyl ether Me.A". [1175°] (R.).

Pyridine (ββ')-dicarboxylic acid

CH C(CO₂H).CH N. Dinicotinic acid. [322°]. Formed by heating pyridine (2,3,5)-tri-carboxylic acid and pyridine (2,3,5,6)-tetra-carboxylic acid (Riedel, B. 16, 1613; Hantzsch a. Weiss, B. 19, 286; Weber, A. 241, 12). Formed also by heating di-chloro-pyridine di-carboxylic acid with

conc. HIAq at 180° (Guthzeit, A. 262, 130). Properties.—Small prisms (from HOAc), split up by heat into CO₂ and nicotinic acid.

Salts.-PbA" 2aq.-Ag.A" aq.-Ag.A" 11aq. -HA'HCl 2aq: needles, decomposed by water.

-HA'₂H₂PtCl₃: orange-red needles. Pyridine (β_7) -dicarboxylic acid (β_7) -dicarboxylic acid Cinchomeronic acid. [259°].

Formation.—1. By oxidation of einchonine or cinchonidine by HNO, of S.G. 1.4 (Weidel, A. 173, 76).—2. By oxidation of quinine by HNO, A. 115, (6).—2. By Ordanton of dinnine by mice, the yield being 28 p.o. (Weidel a. Schmidt, B. 12, 1146).—3. By heating apophyllenic acid with conc. HClAq at 240° (Von Gerichten, B. 13, 1635).-4. By heating pyridine tricarboxylic acid (formed from cinchonic acid) at 190° (Hoogewerff a. van Dorp, B. 13, 61; Skraup, M. 1, 184; Weidel a. Brix, M. 3, 604) .- 5. By the action of KMnO, on methyl-pyridine carboxylic acid and on isoquinoline (Hoogewerff a. van Dorp, R. T. C. 2, 23; 4, 285).—6. By heating pyridine pentacarboxylic acid (Weber, A. 241, 16) .- 7. By oxidation of methyl-nicotinic acid, derived from (B)-collidine (Oechsner de Coninck, Bl. [2] 43, 106). -8. By boiling berberonic acid with HOAc (2 pts.) and Ac.O (1 pt.) for six hours (Mayer, M. 13, 344; cf. Fürth, M. 2, 426).

Properties.—Prisms (from HClAq), v. sl. sol. water and ether, sl. sol. alcohol. Yields isonicotinic and some nicotinic acid on heating (Hoogewerff a. van Dorp, A. 207, 217). Gives pyridine on distillation with lime. Sodiumamalgam yields NH, and cinchonic acid C,H_aO_e, i.e. CO₂H.CH CH, CO (Weidel a. Hoff, M.

CO.H

13, 578). Cinchonic acid [169°] forms mono-10, 0/0). Cincionic acid [109"] forms monoclinic crystals, v. sol. hot water and alcohol, and yields BaC,H₂O₆ Baq, Ba₃(C,H,O,)₂ Saq, CaA" 2aq, Ca₃(C,H,O,)₂ (dried at 190), and oily Et₄A", whence PCl₃, followed by alcohol, yields CO₂Et.CH(CH₂Cl).CH(CO₂Et).CH₂CO₂Et, which is a heavy oil. Cinchonic acid is reduced by HI to butane tricarboxylic acid C,H10O, [184°], whence Ca3A"2 8aq, accompanied by an isomeric butane tricarboxylic acid [133°]. FeSO, gives no colour.

Salts.—Na₄A" 2aq: tables.—NaHA".—BaA" 1½aq: needles, sl. sol. water.—CaA" 3½aq: prisms. — CaA" 3aq. — CuA" 3½aq: small blue crystals.—Ag₂A": white pp.—AgHA".—HA'HCl: monoclinic prisms, decomposed by

water. $-H_2\Lambda'_2H_2PtCl_3$: golden prisms. Anhydride ($C_2H_3N)_2C_2O_3$: [77°]. Formed by boiling the acid with Ac_2O (Goldschmiedt a. Strache, M.10, 156). Plates. May be sublimed. Converted by NH₃ gas into C₅H₃N(CO₂NH₄).CONH₂ [229°], which is converted by heat into a yellow powder [130°], and which yields the amic acid C₅H₂N(CO₂H).CONH₂ [237°], crystallising in

Mono-ethyl ether HEtA". [183°]. Formed from the anhydride and EtOH. Plates (from benzene).-AgEtA": long needles.

Mono methyl ether HMeA". [154°].

Anhydride of the Methylo hydroxide

C_bH,NO, i.e. C_bH,NMe(CO₂H) CO

Apophyllenic acid [242°]. Formed by oxidation of cotarnine by HNO, (Wöhler, A. 50, 24; Anderson, Tr. E. 23, 347; C. J. 5, 257; Gerichten, B. 13, 1635). Formed also by heating cinchomeronic acid with MeI and MeOH at 100° (Roser, A. 234, 116). Needles (anhydrous) or octahedra (containing aq), sol. hot water, insol. alcohol and ether. HClAq at 250° decomposes it, forming cinchomeronic acid and MeCl. - BaA'. $AgA'.-Ag_2A'(NO_3).-H_2A'_2H_2PtOl_3 aq.$

Bromo-apophyllenic acid C.H.BrNO, 2aq. [205°]. Formed by oxidation of bromo-tarconine. Yields BaA', 3aq and H₂A',H.PtCl_s (Gerichten, A. 210, 91). Pyridine (αα'β)-tricarboxylic acid

 $\mathbf{CH} < \begin{matrix} \mathbf{C}(\mathbf{CO}_2\mathbf{H}).\mathbf{C}(\mathbf{CO}_2\mathbf{H}) \\ \mathbf{CH} & \mathbf{C}(\mathbf{CO}_2\mathbf{H}) \end{matrix} > \mathbf{N}. \quad \text{Formed by oxidis-}$ ing di-methyl-nicotinic acid with KMnO, (Weiss, B. 19, 1309). Crystallises from alcohol in plates (containing 2aq), v. e. sol. water. Decomposes at 160° into CO₂ and isocinchomeronic acid. FeSO₄ colours its neutral solution red.—

RH_aA'', 5aq: needles.—Ca₄A'', 2aq.—Pb₃A''', 5aq. Pyridine (aa'7)-tricarboxylic acid

CO₂H.C CH.C(CO₂H) N. Trimesitic acid. Carbolutidinic acid. [244°]. Formed by oxidation of uvitonic acid (Böttinger, B. 13, 2048; 14, 69), and by oxidation of the tri-methylpyridine obtained from acetoacetic ether and aldehyde-ammonia (Voigt, A. 228, 31). Tables or spheroidal groups of needles (containing 2aq), sol. hot water, sl. sol. alcohol and ether. Yields isonicotinic acid on sublimation. FeSO, gives a violet-red colour.

Violet-red colour.

Ethyl ether Et₃A'''. [127.5°].

Amide. [above 280°]. Pyridine $(\alpha\beta\beta')$ -tri-carboxylic acid

CH $\langle C(CO_2H):C(CO_2H)\rangle$ N. Carbodinicotinic acid. [323°]. Formed by oxidation of quinoline $(Py.\ 2)$ -carboxylic acid (Riedel, B. 16, 1615). methyl-pyridine (ββ')-dicarboxylic (Weber, A. 241, 11), and of the parvoline got by heating propionic aldehyde-ammonia with propionic aldehyde at 200° (Dürkopf, B. 21, 832, 2707; 23, 689). Spherical aggregates (containing 1 aq), v. sol. hot water. At 155° it is split up into CO₂ and dinicotinic acid.— Ba₃A'''₂5aq.—Ag₂HA'''1\2 aq: rosettes of plates.

Pyridine $(\alpha\beta\gamma)$ -tri-carboxylic acid $CO_2H.C \stackrel{C(CO_2H)}{\subset} \stackrel{C($

D.; S.); [257°] (D. a. R.). S. 1.2 at 15°.

Formation.-1. By the action of KMnO, on quinine, cinchonine, cinchonidine, quinoïdine, and cinchonic acid (Dobbie a. Ramsay, C. J. 35, 189; Hoogewerff a. van Dorp, B. 12, 158; 13, 152; A. 204, 84; Skraup, A. 201, 312; Strache, M. 10, 642).—2. By oxidation of cinchonine by HNO, (Weidel, A. 173, 101; B. 12, 415).—3. By oxidation of methyl-pyridine (αβ)-dicarboxylic acid (Hoogewerff a. van Dorp, R. T. C. 2, 18), of di-methyl-pyridine carboxylic acid (Michael, B. 18, 2027), of (α)-oxy-cinchonic acid (Weidel a. Cobenzl, M. 1, 865).—4. By oxidation of papaverine (Goldschmiedt, M. 6, 397). Trimetric plates (containing 1 aq), v. sol. hot water, in. sol. alcohol, nearly insol. ether. Blackens at 200°. FeSO, gives a reddish colour. H2S forms a red amorphous body (D. a. R.). Decomposed by long heating at 180°, or by boiling with HOAe into CO₂ and cinchomeronic acid. Yields pyridine on distilling with lime. MeI and MeOH at 100° form CO₂ and apophyllenic acid. Sodium-amalgam gives NH2 and cinchonic acid. PCl, forms a chloride (206° at 40 mm.).
Salts. — K₁A'''3aq. — Ba₂A'''₂16aq. —

Ba₃A", 12aq. — Oa₃A", 14aq. — Ca₄A", 15aq.—

Pyridine (2"), bringshamile of 2

Pyridine $(a\beta'\gamma)$ -tricarboxylic acid $CO_2H.C < CI.CO_2H > N$. Berberonic acid. [243°]. Formed by oxidising berberine with nitric acid (Weidel, B. 12, 410; Fürth, M. 2, 416). Triclinic prisms (containing 2aq), sol. hot water, v. sl. sol. hot alcohol, insol. ether. Yields pyridine on distillation with lime. FeSO, gives a red colour. At 215° it is split up into CO₂ and nicotinic acid; above 243° it yields isonicotinic acid.

Salts. — $K_1A''' 4_3$ aq. — $K_2HA''' 3$ aq. — $K_2HA''' 3$ aq. — $K_2A''' 1_3$ aq. — $Ca_3A'''_2 8$ aq. — $Cd_3A'''_2 4$ aq. — Ag_3A''' : white pp., insol. water.

Pyridine $(\beta\beta'.9)$ -tricarboxylic acid $CO_2H.C \ll C(CO_2H).CH \gg N$. (β) - Carbocinchomeronic acid. [9619] Formed by besting 3^2 .

meronic acid. [261°]. Formed by heating dipotassium pyridine pentacurboxylate at 220° (Weber, A. 241, 17). Plates (containing 3aq), v. sol. hot water. Yields cinchomeronic acid whon heated. Gives no colour with FeSO, Cu₃H₂A'''₄ 24aq.—Ag₃A''' 2aq : crystalline pp. Pyridine $(a\beta\beta'\gamma)$ -tetra-carboxylic acid

 $C_9H_3NO_8$ i.e. $CO_2H.C \ll C(CO_2H) - CH > N$. Formed by oxidising $(\alpha \gamma)$ -di-methyl-pyridine $(\beta \beta')$ -dicarboxylic acid (Weber, A. 241, 23). Prisms (containing 2aq or 3aq). At 120° it loses CO2, forming (β)-carbocinchomeronic acid. FeSO, gives a dark-red colour.—Ba₂A^{1v} 4aq.—Ag,HA^{1v}₂ aq: crystalline.

Pyridine $(aa'\beta\beta')$ -tetracarboxylic acid $CH \stackrel{C(CO_2H)}{\sim} \stackrel{C(CO_2H)}{\sim} \stackrel{C(CO_2H)}{\sim} N$. Formed by oxidisdicarboxylic di-methyl-pyridine (Hantzsch, B. 19, 286; Weber, A. 241, 4). Needles (containing 2aq), v. sol. water. Decomposes at 150° into CO2 and dinicotinic acid.-Call, Aiv 2aq: needles, v. sol. water. - Cu, Aiv 5aq. -Ag Aiv 2aq: bulky pp.

Pyridine $(a\alpha'\beta'\gamma)$ -tetra-carboxylic acid $CO_2H.C \ll \frac{CH}{C(CO_2H)} : C(CO_2H) \gg N$. Formed Formed oxidation of tri-methyl-pyridine carboxylic acid and of di-methyl-pyridine di-carboxylic acid (Michael, A. 225, 142). Formed also by oxidation of flavenol by alkaline KMnO, (Fischer a. Täuber, B. 17, 2927). Slender needles (containing 2aq), v. sol. water, v. sl. sol. alcohol and ether. Not decomposed at 150°. FeSO, gives a brownish-red colour. -Ba, Aiv 2 aq. -Ba, Aiv aq.

-Cu₂A" 2½aq. - Ag₁Aiv aq. Pyridine penta-carboxylic acid NC₃(CO₂H)₃. Formed from potassium tri-methyl-pyridine dicarboxylate and KMnO, (Hantzsch, A. 215, 62; Weber, A. 241, 15). Crystalline mass of minute needles (containing 2aq), extremely sol. water, v. sl. sol. ether. Acid to litmus and to taste. Loses 2aq at 120° and decomposes, without having melted, at 220°. The neutral alkaline salts are very soluble, but the acid alkaline salts are sl. sol. water. The acid does not combine with HCl. Distilled with lime it gives pyridine. FeSO,

gives a dark-red colour,

Salts.-KHA 2 or Saq. When heated swells up like Pharaoh's serpent.—K,H,A*8;aq.

— K,A*. — Ba,A*, 11aq. — Ca,A*, 12aq. —

CaH,A*;aq.—Mg,A*, 12aq.—Ca₂(NH,)A*ŏaq.—

KH,AvKHC,O, 5aq.

References. - BROMO- and OXY-PYRIDINE CARB-OXYLIC ACID.

PYRIDINE TETRAHYDRIDE C.H.N i.e. CH2 CH : CH NH. Piperidein. Formed by heating amido-valeric aldehyde with solid KOH (Wolffenstein, B. 25, 2782).—B'HAuCl,. [141°]. —B₂'H₂PtCl₄.—B'HCl. [230°].—B'HBr. [178°].

Pyridine hexahydride v. PIPERIDINE. PYRIDINE (B)-SULPHONIC ACID

C.H.N.SO.H. Formed by heating pyridine (1 pt.) with H.SO. (3 pts.) at 320° (O. Fischer, B. 15, 62; 16, 1183). Small needles or plates, sol. water, sl. sol. alcohol, insol. ether. Br added to its boiling aqueous solution forms dibromopyridine. Potrsh-fusion gives oxy-pyridine [123°]. On distillation with KCy it yields the nitrile of nicotinic acid. The K salt, heated with MeI at 150° forms crystalline C₅H₄NMe< SO₂

(Hantzsch, B. 19, 36).—BaA', 4aq: needles. Pyridine sulphonic acid? C₅H₅NSO₃. [155°]. Formed from pyridine and ClSO₃H (Wagner, B. 19, 1157). Crystalline, decomposed

by water into pyridine and H₂SO₄.

Pyridine disulphonic acid C₅H₃N(SO₃H)₂. Formed by heating piperidine (1 pt.) with H.SO. (10 pts.) (Königs, B. 16, 735; 17, 592). Needles (from HOAc), v. sol. water, nearly insol. alcohol and ether. PCl. at 200° forms tri-chloropyridine [48°]. — Na₂A" 4aq. — K₂A" 3aq. — PbA" 4 ag.

PYRIDONE v. OXY-PYRIDINE.

(aa)-DIPYRIDYL C₁₀H₂N₂ i.e. C₃H₄N.C₃H₄N. [70°]. (272·5°). V.D. 5·6. Formed by distilling cupric picolinate (Blau, B. 21, 1077; M. 10, 875). Crystals (from water), m. sol. water, v. sol. alcohol. Not hygroscopic. Strong base. FeSO, colours its aqueous solution red. Oxidised by KMnO, to picolinic acid.—B"H_PtCl..— B"H_FeCy..—B"C.H_N.O.. [155.5°]. Needles Hexahydride. Formed by reducing the

base with zino and HClAq. Alkaline oil.

Dodecahydride C₁₀H₂₀N₂. Dipiperidyl.

(259° cor.). Formed by reducing the base, dissolved in isoamyl alcohol, by Na. Powerful base. Very deliquescent. Not poisonous. Forms with

Very deliquescent. Not poisonous. Forms with OS₂ a compound [93°], and yields a nitrosamine [159°].—B'H₂PtCl₂ 2½aq.
(ββ).Dipyridyl C₁₀H₂N₂. [68°]. (287°) (L.
a. O.); (292° at 736 mm.) (S. a. V.). Formed by distilling its dicarboxylic acid with KOH (Skraup a. Vortmann, M. 4, 591), and by the dry distillation of pyridine disulphonic acid (Leone a. Oliveri, G. 15, 276). Extremely deliquescent needles, miscible with water and alcohol, sl. sol. ether. Yields nicotinic acid on oxidation.—B"_H_PtCl_s.—B"2C,H_N_sO_r. [232°].

Hexahudride C...H_s,N_x. Nicotidine.

C,0H,1N2. (288°). Got by warming the base with tin and conc. HClAq. Poisonous oil, v.e. sol. water and alcohol, m. sol. ether.—B"₂H₂PtCl₆: orange-red pp.—Picrate: [202°].

 $(\gamma\gamma)$ -Dipyridyl C₁₀H₈N₂. [114°]. (305° cor.). V.D. 5'9 (calc. 5'5). Formed by boiling pyridine with sodium (Anderson, A. 154, 274; Weidel a. Russo, M. 3, 854). Formed also by heating its (aa)-dicarboxvlic acid with HOAc at 180° (Heuser a. Stochr, J. pr. [2] 44, 407). Tables, sl. sol. cold water, v. sol. alcohol. Crystallises from water in tables (containing 2aq). [73°]. Tastes bitter. Yields isonicotinic acid on oxidation. Br forms C10H6Br2N2 crystallising from alcohol in needles. MeI and EtI form crystalline B"2MeI and B"2EtI respectively.

Salts. — B"H₂Cl₂. Monoclinic crystals; a:b:c=1.064:1:.595. $\beta=112^{\circ}$ 33'.—B"H₂ZnCl₄. Monoclinic tables; -- B"H₂HgCl₄. β=91° 3'. — B"H,PtCl₆. – = .673:1: .341;

action of Na on pyridine (Anderson, C. J. 22, 406; Weidel, M. 3, 879). Liquid, sol. water and alcohol.—B"H₂PtCl₈. — B"2MeI. — B"Me₂PtCl₆

(Ramsay, C. J. 36, 264).

Hexahydride $C_{10}H_{14}N_{2}$. Isonicotine. [78°]. (above 260°). Formed by reducing $(\gamma\gamma)$ -dipyridyl with tin and HClAq (W. a. R.). Deliquescent needles, sol. water, alcohol, and benzene. Has hardly any smell. Strongly alkaline and caustic. Poisonous, acting somewhat like curari. Its salts are much less poisonous. Oxidised by KMnO. to isonicotinic acid. -B"2HNO3. Deliquescent needles. - B"H_PtCl3 aq. - B"_H_Hg_3Cl10. -B"2MeI: triclinic prisms (from MeOH).

Dodecahydride $C_{10}H_{20}N_2$. [122°]. Formed by reducing $(\gamma\gamma)$ -dipyridyl in alcohol by Na (Ahrens, B. 21, 2929). Needles, insol. water, v. sol. alcohol and ether.—B"H_PtCl_s.—B"HAuCl_s. Picrate: needles, blackening when heated.

Dipyridyl C₁₀H₈N₂ (281°). Formed by passing pyridine vapour through a red-hot tube (Roth, B. 19, 360). Oil.—B"2HCl: hygroscopic needles.—B"H.PtCl.—Piorate: [208°].

(αβ) Dipyridyl C₁₀H₁N₂. (296° cor.). Formed by heating its carboxylic acid with lime (Skraup a. Vortmann, M. 3, 599; Blau, B. 24, 326). Oil, sol. alcohol and ether. — B"H_2PtCl₁ aq. — B"C₂H₃N₃O₇. [149·5°]. Yellow needles. Dodecahydride C₁₀H₂₀N₂. [69°]. (269°

cor.). Formed by reducing the base with isoamyl alcohol and Na (Blau, M. 13, 332). Hygroscopic crystalline mass. Not identical with nicotine hexahydride. Strongly alkaline, absorbing CO₂ from the air. V. e. sol. water, but much water gives a turbidity. V. sol. alcohol, m. sol. ether. CS₂ forms a compound [205°].—B"H₂Cl₂. V.e. sol. water, sl. sol. alcohol and ether.—B"H₂PtCl₂ 2aq. [238°]. — B"2HAuCl₄. [212°]. — B"2C₄H₃N₄O₇. [215°].

Bensene sulphonyl derivative. [157°]. Nitrosamine C₁₀H₁₈N₂(NO)₂ [88°]. Dipyridyl dodecahydride? C₁₀H₂₀N₂? (251°). S.G. 4 ·956. Is perhaps (αβ)-dipyridyl hexa-hydride (Blau). Formed by the action of Na on nicotine in alcoholic solution (Liebrecht, B. 18, 2970; 19, 2590). Lævorotatory liquid, v. sol. water, alcohol, and ether. Alkaline in reaction. Smells like piperidine. Readily unites with CS. Forms an oily nitrosamine and an oily di-acetyl derivative (c. 405°).—B"2HCl. Sol. alcohol.—B"H,PtCl. [202°].—B"H,I.: brown needles.— B"2HAuCi, [182°].—B"H₂Hg,Ci, —B"Me,PtCl, —O₁₀H₁₀MeN₂Me,PtCl, Blau (M. 13, 341) by reducing nicotine obtained a mixture of bases (235°-265°) yielding a sparingly soluble platinochloride [218°], which gave a base (244°), possibly methyl-nicotine hexahydride C11H22N2

(a)-PYRIDYL-ACRYLIC ACID C.H.NO. i.e. C,H,N.CH:CH.CO₂H. [203°]. Formed by heating a-oxy-tri-w-chloro-propyl-pyridine with alcoholic potash (Einhorn, B. 20, 1593; 23, 220; A. 265, 215). Got also by heating a-oxy-pyridylpropionic acid. Small transparent needles, v. sl. sol. cold water, v. sol. alcohol.

Reactions. - 1. Br in HOAc forms C.H.N.CHBr.CHBr.CO.H [127°], which melts at 146.5° when containing HOAc of crystallisation.-2. Hydrogen bromide in HOAc forms (C,H,N.CHBr.CH,CO,H)HBr [164°], crystallising in needles.—3. MeI yields HA'MeI [220°] converted by AgBr into HA'MeBr [242°].

Salts.—HA'HCl. [220°].—H₂A'₂H₂PtCl₂. [210°]. Red prisms.—HA'HAUCl₄. [195°].— HA'HBr. [223°].—CaA',.—AgA': ncedles.

Methyl ether MeA'.—MeA'HCl. [186°].—

MeA'HBr. [242°]. MeA'HI. [220°].

Ethul ether EtA'. Needles.

(a)-PYRIDYL-BUTYLENE C₅H₄N.CH:CHEt. (148° at 75 mm.). By distilling oxybutyl-pyridine C₅H₄N.CH₂.CH(OH).C₂H₅ with KÖH in vacuo or by heating it with HClAq at 165° (Matzdorff, B. 23, 2711). Colourless oil, smelling like conyrin. - Platinochloride:

[140°], - B'HAuCl, [130°], Small needles.
(αβ).DIPYRIDYL (β).CARBOXYLIC . ACID
C₁₁H₄N₂O₂ i.e. C₅H₁N.C₅H₂N.CO₅H. [183°]. Formed by heating the dicarboxylic acid at 200° (Skraup, B. 15, 896; M. 3, 597). Needles (containing 1 aq), sl. sol. cold water and alcohol. Gives a yellow colour with FeCl, -- CaA', 2aq .-AgA' jaq: prismatic needles.

 $(\alpha\beta)$ -Dipyridyl $(\beta\gamma)$ -dicarboxylic acid $\mathbf{CH} \leqslant_{\mathbf{N}}^{\mathbf{CH}:\mathbf{C}(\mathbf{CO}_{2}\mathbf{H})} \geqslant_{\mathbf{C}.\mathbf{C}} \leqslant_{\mathbf{N}}^{\mathbf{C}(\mathbf{CO}_{2}\mathbf{H}):\mathbf{CH}} \geqslant_{\mathbf{CH}} \mathbf{CH}.$

Formed by oxidation of phenanthroline by KMnO, (Skraup a. Vortmann, B. 15, 896; M. 3, 587). Triclinic prisms (containing 2aq), sl. sol. cold water, v. sol. alcohol. FeSO, colours its aqueous solution red. Salts.—KHA", aq. has aqueous souther test. Sarts.—AIA __aq.,—CaA'' Baq.—CuA'' Saq.—BaA'' 12aq. Crystals.—AgHA'' 4aq.—H₂A'' 2HCl.—H₂A''H₂PtCl₆ 3aq.—(H₂A'')₂H₂PtCl₆ 6aq : golden prisms.

(ββ)-Dipyridyl (αα)-dicarboxylic acid C₁₂H₈N₂O₄. [213°]. Formed by oxidation of pseudo-phenanthroline by KMnO (Skraup a. Vortmann, M. 4,583). Thick prisms (containrotanani, at. 2, 005). The prisms (containing \(\frac{1}{2}\) aq), sl. sol. cold water, alcohol, and ether. FeSO, gives an orange-yellow colour.—K_\(\Lambda \) "5aq.— KHA" 2aq.— CaA" 5aq.— CuA" 3\(\frac{1}{2}\) aq.—Ag_\(\Lambda \) "AgNO_\(\lambda \).—H_\(\Lambda \)" HCl aq. Monoclinic prisms; \(a; b:c = 1.27.1:2.29; \(\beta = 1.10^{\circ} \) 16'.—

H.A. H.PtCl₂ Saq: orange crystalline pp.
(γγ).Dipyridyl (αα).dicarboxylic acid.[247·5°].
Formed by oxidising (αα).di-methyl-dipyridyl by KMnO, (Heuser a. Stoehr, J. pr. [2] 44, 405).
Needles y all sol, water and alcohol. Fe8O. Needles, v. sl. sol. water and alcohol. FeSO gives a reddish-yellow colour. AcOH at 1800

gives (γγ)-dipyridyl.

Dipyridyl tetracarboxylic acid? [96°]. Got
by oxidising diquinolyl (Claus, B. 14, 1942). Needles (from hot water).—Pb.Aiv.—Ag.Aiv.

PYRIDYLENE-PHENYLENE-KETONE

PHENYLENE PYRIDYL KETONE.

Pyridylene-phenylene-ketone sulphonic acid $\begin{bmatrix} 3_2^1 \end{bmatrix} C_t H_s(SO_tH) < \begin{matrix} CO.U:N-CH \\ C-C:CH.CH \end{matrix}$ Formed by oxidising (8)-naphthoquinoline sulphonate with alkaline KMnO, (Immerheiser, B. 22, 408). Yellow plates (from water), v. sl. sol. alcohol and ether. Yields an oxim crystallising in yellow flakes and a phenyl-hydrazide crystal-lising in minute orange needles.—KA' aq.— BaA', 2nq.—PbA', 3aq.—AgA' aq.

PYRIDYL-ETHYLENE C,H,N.CH:CH, (160°). Formed by the action of NaOHAq on the hydrochloride of β-bromo-β-pyridyl-propionic acid (Einhorn, B. 23, 221; A. 265, 229). Liquid.—B'HAuCl4. [144°]. Yellow needles.

(a)-PYRIDYL ETHYL KETONE C.H.NO i.s. C₅H₄N.CO.C₂H₅. (205°). Formed by distilling calcium picolinate with calcium propionate (Engler a. Bauer, B. 24, 2530). Oil, sol. alcohol. Sodium-amalgam forms a pinacone [136° Phenyl-hydrazine sulphonic acid vields a crystalline compound [268°].—B'HgCl2: crystalline.— B'EtI. [160°].

Oxim C.H.N.C(NOH).C.H. Needles. Yields an acetyl derivative [46°] and

a benzoyl derivative [69°].

(β)-Pyridyl ethyl ketone C,H,N.CO.C,H, Formed by distilling calcium nicotinate with calcium propionate (Engler, B. 24, 2539). Yields a phenyl hydrazide [145°] and a phenyl-hydrazide sulphonate [235°] which forms B'2H2PtCl2. $B'C_0H_3N_4O_n$, and $B'HgCl_2$ [130°]. $Oxim C_5H_4N.C(NOH).C_2H_3$.

(a) PYRIDYL METHYL KETONE C₅H₄N.CO.CH₃. (192°). Formed by distilling calcium picolinate with calcium acetate (Engler a. Rosun.off, B. 24, 2527). V. sol. alcohol and ether. Readily volatile with steam. Yields an oxim [120°], a phenyl-hydrazide [155°], and a phenyl-hydrazide sulphonate which is not melted at 300°.—B'C.H.N.O.. [131°].—B'HgCl., [150°].—B'MeI. [161°].—B'EtI. [205°]. (β)-Pyridyl methyl ketone C.H., N.CO.CH.,

(220°). Formed by distilling calcium nicotinate with calcium acetate (Engler a. Kiby, B. 22, 597). Oil, v. sol. acids. Yields an oxim [112°], which yields B'HCl [204°]. The phenyl-hydrazide [137°] crystallises from alcohol in yellow needles.—B'HgCl,. [158°]. White needles.

DI-(a)-PYRIDYL-PROPANE C13H11N2 i.e. CH (CH, C, H, N), (323°). S.G. 1.0281 Formed by heating picoline with methylal and ZnCl₂ for 10 hours at 290° (Ladenburg, B. 21, ZnCl₂ for 10 hours at 290° (Ladenburg, D. 21, 3100). Yellow oil, v. sol. alcohol and ether.—Salts: B"H₂PtCl_e. [215°]. - B"2HAuCl₄ 1½aq. -B"H₂Hq,Cl₉. [161°]. Large plates.

Dodecahydride C₁₃H₂₆N₂. Dipipecolylmethane. [54°]. (195° at 26 mm.). Formed by reducing the base with Na and alcohol.

Crystalline mass, sl. sol. water .- B"2HCl: very hygroscopic needles. - B"2MeCl. [171°]. C₁₃H₂₁Me₂N₂2MeI. Crystals, v. e. sol. water.

(a) PYRIDYL PROPYL KETONE

O.H.N.CO.Pr. (216°-220°). Formed by distilling calcium picolinate with calcium butyrate (Engler a. Majmon, B. 24, 2536). Oil. Yields an oxim [48°] which forms a benzoyl derivative [57°]. Forms a phenyl-hydrazide [82°] and a phenyl-hydrazide sulphonic acid [251°]. ketone is reduced, in dilute alcoholic solution, by sodium-amalgam to a pinacone $C_{18}H_{21}N_2O_2$ [146°]. The chloro-iodide melts at 85°.

Salts.— $B'_2H_2PtCl_8$.— $B'HgCl_2$. [c. 78°].

B'MeI. [79°].

(8) Pyridyl propyl ketone C₃H₄N.CO.Pr.
(246°-252°). Formed by distilling calcium nicotinate with calcium butyrate (Engler, B. 24, 2541). Yellow needles, sol. alcohol. Yields a phenyl-hydrazide [182°], a phenyl-hydrazide sulphonate [283°], a crystalline oxim, and an ethylo-iodide [192°]. - B'HgCl₂. B'C,H,N,O,

(B.3)-(a)-PYRIDYL-QUINOLINE $C_{14}H_{10}N_2$ i.e. CH.CH.C.CH:ÇH

CH. N .C.CH.C.C, H.N [104°]. Formed by heating the Ag salt of its carboxylic acid (O. Fischer a. H. van Loo, B. 19, 2475). Prisms.— ${
m B'_2H_2PtCl_6}.$ Carboxylic acid ${
m C_{15}H_{10}N_2O_2}$ i.e.

 $C_{\nu}H_{\nu}N.C \leqslant_{N-CH}^{CH:CH} \geqslant C.CO_{\nu}H.$ [273°]. Formed by oxidising (\$)-diquinolyl with CrO. Needles, v. sl. sol. water .- AgA': pale yellow pp.

PYRO. Use of this prefix applied to in-organic compounds; for pyro- compounds v. the compounds to the names of which pyro- is prefixed. Thus pyro-phosphoric acid will be found under Phosphoric Acid, and pyro-phos-

phates under Phosphates.

PYROCATECHIN C.H.O. i.e. C.H.(OH),[1:2]. Catechol. o-Di-oxy-benzene. Oxyphente acid. [104°] (F. a. M.); [111°] (Mortinon). (240°–245°). H.C.p. 685,200. H.C.v. 684,900. H.F. 85,800 (Stohmann, J. pr. [2] 45, 334). Occurs in urine, especially after administration of benzene or phenol (Baumann, H. 1, 244; 3, 157; Nencki a. Giacosa, H. 4, 335; Schmiedeberg, H. 6, 189). Occurs in the green leaves of the Virginia creeper (Ampelopsis hederacea) (Gorup-Besanez, B. 4, 905) and in the sap of the plants from which kino is prepared (Fluckiger, B. 5, 1). Occurs sometimes in raw beet sugar (Lippmann, B. 20, 3298). Occurs in wood-tar (Béhal a. Desvignes, Bl. [3] 9, 141).

Formation .- 1. By dry distillation of catechin. moritannic acid, and all varieties of tannin that turn green with FeCl₃ (Zwenger, A. 37, 327; Wagner, J. pr. 52, 450; 55, 65; Eissfeldt a. Uloth, 4. 92, 101; 111, 215).-2. By the dry distillation of wood (Buchner, A. 96, 188). -3. By heating cellulose, starch, or cane sugar with water at 200°-280° (Hoppe-Seyler, B. 4, 15).-4. By potash-fusion from o-iodo-phenol (Körner, Bull. Acad. Belg. [2] 24, 166; Lautemann, A. 120, 315).—5. By the action of HI on guaiacol (Gorup-Besanez, J. 1867, 688; Baeyer, B. 8, 155).—6. By the dry distillation of protocatechuic acid and of quinic acid (Strecker, A. 118, 285; Hlasiwetz a. Barth, J. 1864, 405; Tiemann a. Haarmann, B. 7, 617).—7. By potash-fusion from o-phenol sulphonic acid (Kekulé, Z. 1867, 643), benzoic acid, gum guaiacum (Hlasiwetz a. Barth, A. 130, 352; 134, 282), and, together with resorcin, from o- and m- bromo-phenol (Fittig, B. 8, 364).-8. By soda-fusion from phenol (Barth a. Schreder, B. 12, 419) .- 9. From phenol and H₂O₂ (Martinon, Bl. [2] 43, 157).— 10. By passing a rapidly alternating electric courrent through a solution of phenol.—11. A

product of the action of water at 200° on bens. ene hexachloride (Meunier, C. R. 100, 1591).

Preparation.—1. From HIAq and guaiacol at 200° or by heating guaiacol with conc. HClAq for 4 hours at 175° (Perkin, jun., C. J. 57, 587). 2. By fusing o-phenol sulphonic acid with potash at 350° (Degener, J. pr. [2] 20, 308).

Properties .- Large plates (from benzene) or needles (from water), v. sol. water, alcohol, and ether, m. sol. benzene and chloroform. insol. ligroin. Gives an acid reaction in presence of borax (Lambert, C. R. 108, 1017). FeSO, gives no colour. FeCl, colours the aqueous solution green, turned violet-red by alkalis (Ebstein a. Müller. Fr. 15. 465). The alkaline solution Müller, Fr. 15, 465). The alkaline solution absorbs oxygen, becoming brown. It reduces AgNO3, AuCl3, and platinic chloride. Ppts. a conc. solution of egg-albumen. Does not ppt. gelatin. Lead acetate gives a white pp. Quinone in ethereal solutions forms C.H.O.C.H.O.20 crystallising in deep-green needles with violet lustre [153°] (Clermont a. Chantard, C. R. 102, 1072). Ppts. a solution of quinine sulphate, forming C., H2, N.O. H2SO, C.HeO, aq, which separates from alcohol in yellow crystals [167°], v. sl. sol. cold water.

Reactions .- 1. Nitric acid acts violently, forming oxalic acid .- 2. Phthalic anhydride and ZnCl₂ at 150° form 'pyrocatechin phthalein'

C(C₆H₃(OH)₂)₂, a yellow mass forming

a blue solution in alkalis and yielding a tetrabenzoyl derivative [202°] (Baeyer a. Kochendörfer, B. 22, 2196). 3. Phenyl cyanate at 100° forms CaH4(O.CO.NHPh)2 [165°] crystallising in needles, v. sol. alcohol (Snape, C. J. 47, 772). 4. The disodium compound C₆H₄(ONa)₂ treated with CO₂ in the cold forms C₆H₄(O.CO₂Na)₂, which at 100° changes to the compound C, H, (O.CO, Na) (OH).CO, Na and at 210° to C_aH₂(OH)₂(CO₂Na)₂ (Schmitt a. Hähle, J. pr. [2] 44, 2).—5. Ammonium carbonate and water at 140° react forming protocatechuic acid and C_oH₄(OH)(CO₂H)₂[1:2:3].—6. K₂S₂O₇ acting on K salt forms crystalline C_oH₄(O.SO₂K)₂ and C₆H₄(OH)(O.SO₃K) (Baumann, B. 11, 1913).—7. Cl.CONH₂ forms C₆H₄(O.CONH₂)₂ [178°] crystallising from alcohol in needles. -8. Chlorine passed into its solution in acetic acid forms

CCl CCl₂CO crystallising (with 2aq)

from ether-ligroin, and from ligroin (with aq). melting at 94° (Zincke a. Klein, B. 21, 2719).-9. KOH and ClCO,Et form C₄H,CO₃ [118 [118°] (Bender, B. 13, 697), (225°-230°) (M. Wallach, A. 226, 84).

Estimation. - By extracting its acidified aqueous solution with ether, evaporating the ether, dissolving the residue in water, and precipitating with lead acetate. The pp. is dried at 100° and weighed (Degener, J. pr. [2] 20, 303).

Salt s.—C_oH₄O₂Pb. White pp.—C_oH₂O₃Sb or

 $C_eH_4 < O$ SbOH. Formed by adding SbCl₃ to a

solution of pyrocatechin saturated with NaCl (Causse, Bl. [3] 7, 245). Prisms, insol. water, alcohol, and ether, sol. alkalis and mineral acids. Ac2O at 125° forms C.H. (OAc), and Sb(OH) (OAc),. Di-acetyl derivative C.H. (OAc),

Di-acety lNeedles (Nachbauer, A. 107, 248).

Di-bensoyl derivative [84°]. Plates (Doebner, A. 210, 261; Hinsberg, 4. 254, 254).

Mono-methyl ether C₆H₁(OH)(OMe). Guaiacol. Mol. w. 124. [28·5°]. (205°) (Tiemann a. Koppe, B. 14, 2016; Béhal a. Choay, Bl. [3] 9, 142). S.G. 16 1·125 (V.); 21·153; 15 1·143 (B. a. C.). A product of distillation of gum guaiacum (Sobrero, A. 48, 19; Deville a. Pelletier, A. 52, 403; Völckel, A. 89, 349). Occurs among the products of the distillation of wood (Hlasiwetz, A. 106, 362; Gorup-Besanez, A. 143, 151). Prepared by heating calcium vanillate with slaked lime (Tiemann, B. 8, 1123) and by heating pyrocatechin with MeI and KMeSO, (Gorup-Besanez, A. 147, 248, or with NaOMe, McOH, and MeI). Liquid, with peculiar odour, sol. alcohol and ether, sl. sol. water, sol. dry glycerin and ligroïn. FeCl, gives a green colour in its alcoholic solution. Dissolves in alkalis. Yields C.H. OMe on heating with zinc-dust (Marasse, A. 152, 64). PCl, forms C,H,Cl.OMe (Fischli, B. 11, 1463). I and KOHAq give a coffee-brown pp. [125°-130°] (Messinger a. Vortmann, B. 22, 2320). The K salt is converted by acetochlorhydrose into $C_8H_4(OMe)(O.C_8H_{11}O_5)$ [157°] (Michael, Am. 6, 339). Phthalic anhydride and SnCl, at 115° form 'guaiacol-phthalein,' which yields a crystalline benzoyl derivative (Baeyer, B. 22, 2199). H₂SO₄ forms two sulphonic acids (Tikmann a. Koppe, B. 14, 2019).— C₀H₄(OK)(OMe) 2aq.—KHA'₂ aq: prisms (from alcohol), decomposed by water.—Pb(OH)A': flocculent pp. — C₂H₄(O.SO₃K)(OMe): white needles.—C₄H₄(OAc)(OMc). (235°-240°). V.D. 82·7 (obs.). Colourless liquid.

Di-methyl ether C_vH₄(OMe)₂. Veratrole. (205°). V.D. 68·6 (obs.; H=1). S.G. 15 1·086. Formed by heating veratric acid with baryta (Merk, A. 108, 60; Koelle, A. 159, 243; Tiemann, B. 14, 2016). It is obtained also from C, H, (OK) (OMe) and MeI (Marasse). Solidified

at 15°.

Methyl ethyl ether $C_0H_1(OMe)(OEt)$. (213°). V.D. (H=1) 75 6 (obs.). Liquid.

Methyl propyl ether C.H.(OMe)(OPr). (240°-245°). Liquid (Cahours, Bl. [2] ??, 270). Di-ethyl ether C.H.(OEt)... [44°]. Formed from pyrocatechin, Etl., and alcoholic potash

(Herzog a. Zeisel, M. 10, 152).

Di-benzyl derivative C6H4(OC,H4)2. [61°]. Yellowish needles (from alcohol). Forms a nitro-derivative crystallising in needles [98°].

The mono-benzyl derivative is liquid, but its nitro-derivative forms yellow needles (from alcohol) [129°] (Schiff a. Pellizzari, A. 221, 378; G. 13, 507).

Sulphonic acid $C_8H_3(OH)_2(SO_3H)[4:3:1]$. Formed by fusing phenol (a) disulphonic acid with KOH at 300° (Barth a. Schmidt, B. 12, 1260). Deliquescent needles, v. sol. water and alcohol, insol. ether. - KA'. - NaA'aq. - BaA'2.

References .- AMIDO-, BROMO-, CHLORO-, and NITRO- PYROGATECHIN, and TRI-BROMO-GUAIACOL.
PYROCINCHONIC ACID v. DI-METHYL-

MALEÏO ACID.

PYROCOLL C₁₀H₀N₂O₂ (Magnanini, B. 22, 2502). [269°]. A product of the distillation of gelatin when free from fat but containing albumen, casein, or gluten (Weidel a. Ciamician, M. 1, 279; 2, 29). Formed also, together with

C.H.(OBz)2. | HOAc, by heating the scetyl derivative of pyr-Tole (a)-carboxylic acid (Ciamician a. Silber, B. 17, 103; G. 14, 162, 563). Colourless plates, insol. water and cold alcohol, sl. sol. ether. Sublimes before fusion.

Reactions.-1. Boiling KOHAq converts it into pyrrole carboxylic acid .- 2. Alcoholic NH, forms the amide of pyrrole carboxylic acid. -3. PCl₃ forms C₁₀Cl₆N₂O₂ [above 320°] insol. ether and C₁₀Cl₁₀N₂O [197°] sol. ether (Ciamician a. Danesi, G. 13, 28). The perchloro-pyrocoll C10Cl6N2O2 is converted by boiling KOHAq into tri-chloro-pyrrole carboxylic acid, and by PCl. the C₁₀Cl₁N₂O₂ [1479]. 4. Bromine forms C₁₀H₃Br₁N₂O₂ [192°], C₁₀H₄Br₂N₂O₂ [290°], and C₁₀H₄Br₄N₂O₂, which is converted by KOHAq into di-bromo-pyrrole carboxylic acid (Ciamician, G. 11, 330; 12, 29; B. 16, 2388).

Reference.-CHLORO-, BROMO-, and NITRO-Pyrocoll.

PYROCRESOL. C₁₃H₁₁O? An inappropriate name given by Schwarz (B. 15, 2201; 16, 2141; M. 3, 726; cf. Armstrong, C. J. Proc. 3, 114) to some neutral substances found in coal-tar.

(a)-Pyrocresol [195°]. Thin silvery plates, yielding crystalline $C_{2n}H_{2\nu}Br_3O_2$? and oxidised by CrO_1 in HOAc to $C_{1\nu}H_{1\nu}O_2$ [168°] which yields $C_{1\nu}H_{1\nu}(NO_2)O_2$ [235°], $C_{1\nu}H_{1\nu}(NO_2)O_2$ and $C_{1\nu}H_{1\nu}(NO_2)O_2$ [235°], $C_{1\nu}H_{1\nu}(NO_2)O_2$ and $C_{1\nu}H_{1\nu}(NO_2)O_2$ [230°]? (Bott a. Miller, C.J. 55, 52). Chlorine acting on a solution of (a)-pyrocresol in chloroform gives C15H11Cl3O [225°]? HI reduces (a)-pyrocresol to a hydrocarbon C15 II 22? (Bott, C. J. Proc. 3, 114).

(a)-Pyrocresol [c. 124°]. Yields, on oxidation, '(B)-Pyrocresol oxide ' $C_{13}H_{12}O_{2}$ [95°]. (b)-Pyrocresol [165°]. Yields '(γ)-Pyrocresol oxide ' $C_{13}H_{12}O_{2}$ [95°]. oxide ' $C_{13}H_{12}O_{2}$ or oxidation. Bromine forms $C_{28}H_{12}Br_{2}O_{2}$? crystallising in trimetric plates.

PYROGALLIC ACID v. PYROGALLOL PYROGALLOL C.H., O. i.e. C. H., (OH), [1:2:3]. c-Tri-oxy-bensene. Pyrogallic acid. Mol. w. 126. [131°] (Etti, B. 11, 1882; cf. Stenhouse, A. 179, 236); [134°] (Stohmann). (210°). S. 40 at 12°. 40 at 12°. H.C.p. 633,300 (Berthelot a. Louguinine, A. Ch. [6] 13, 339; C. R. 104, 1577). H.F. (from diamond) 137,700 (B. a. L.); 132,000 (Stohmann, J. pr. [2] 45, 336). Occurs in woodtar as dimethyl ether.

Formation .- 1. By heating gallic acid (alone or mixed) with pumice stone (2 pts.) (Braconnot, A. 1, 26; Pelouze, A. 10, 159; Licbig, A. 101, 47).-2. By heating di-iodo-o-oxy-benzoic acid with KOHAq (Lautemann, A. 120, 299) .- 3. By heating (a)- or (β) - chloro-phenol sulphonic acid with KOH at 190° (Petersen a. Baehr, A. 157, 136).-4. By heating gallic acid (10 g.) with glycerin (30 c.c.) at 200° as long as CO₂ comes off (Thorpe, Ph. [3] 11, 990).-5. By heating gallic acid (1 pt.) with aniline (2 pts.) at 120° (Cazeneuve, Bl. [3] 7, 549). The product is aniline pyrogallate $C_6H_8O_32NPhH_2$ [56°], which gives off aniline when exposed to air, or when shaken with benzene.

Properties. - Prisms, v. sol. water, m. sol. alcohol and ether. Tastes bitter. Poisonous (Personne, Z. [2] 5, 728). Its alkaline solution rapidly absorbs oxygen, turning brown, and giving off a little CO in bulk about 30th of the oxygen absorbed (Calvert a. Cloez, A. 130, 248). Beduces KMnO, (Monier, C. R. 46, 577) and salts of mercury, Ag, Au, and Pt. FeSO, gives

a white milkiness, but if a ferric salt is present, or the pyrogallol solution has become slightly exidised by keeping, FeSO, gives an indigo-blue colour, changing to brownish red on standing and on adding HCl (Jacquemin, C. R. 77, 593; Cazeneuve, Bl. [2] 44, 114; C. R. 101, 56). FeCl., in absence of air, gives a transient blue colour, restored by cautious addition of alkali. A solution of pyrogallol renders borax slightly acid (Lambert, C. R. 108, 1017). Nitrous acid colours the aqueous solution brown (Schönbein, Fr. 1, 319). K₂CrO₄ and H₂SO₄ give a dark colour. Reduces CuSO₄ and, on addition of alkalis, gives a black colour changed by NH, to red. Cu(OAc)₂ gives at once a black colour. Pyrogallol fused with ammonium oxalate yields ammonium rufigallate, which dissolves in water with red colour and gives with K3FeCy, and K_Cr_O, a dark-brown pp. insol. alcohol (Kliebahn, Fr. 26, 641). A solution of iodine in presence of Na SO, gives a purple colour (Nasse, B. 17, 1186). A solution of HgCl, and pyrogallol in alcohol gives a black pp. with alkaloids but not with glucosides (Schlagdenhaufen, Ph. [3] 4, 772). An alkaline solution of pyrogallol absorbs about 50 vols. of NO in 12 hours, but no N₂O (Russell a. Lapraik, C. J. 32, 35). Pyrogallol does not react with hydroxylamine (Baeyer, B. 19, 163). A solution of potassium pyrogaliate which is absorbing oxygen in contact with alumina gives out a feeble light, especially in presence of Na.S (Lenard a. Wolf, P. [2] 34, 918).

Reactions .- 1. Fuming HNO, forms oxalic acid .- 2. Bromine forms tri-bromo-pyrogallol .-8. Chlorine in presence of HOAc forms mairogallol (vol. iii. p. 165) and crystalline leucogallol C18H8Cl12O12 2aq, which yields tri-chloro-pyrogallol when boiled with water and zinc-dust (Stenhouse a. Groves, C. J. 28, 706; Webster, (Stenhouse a. Groves, C. J. 28, 706; Webster, C. J. 45, 208; Hantzsch a. Schniter, B. 20, 2033).—4. Ozone passed through a solution of pyrogallol (1 mol.) and KOH (3 mols.) in water forms a syrupy acid C₄H₄O₇, which yields BaC₄H₄O, (Boeke, B. 6, 486).—5. Purpurogallin or pyrogalloquinone is formed by oxidation by alcoholic AgNO₃, by KMnO₄ and H₂SO₄, or by excess of FeCl₄ (Girard, C. R. 69, 865). It is also got from pyrogallel and quinone (Wichelbaus. got from pyrogallol and quinone (Wichelhaus, B. 5, 847; Nietzki, B. 20, 1278). It forms garnet-fed needles (by sublimation), sl. sol. water, m. sol. alcohol and ether, forming yellow solutions. Alkalis impart a transient blue colour. Purpurogallin dyes cotton mordanted with alumina violet-blue. When an aqueous solution of pyrogallol is mixed with gum arabic and exposed to the air, purpurogallin C20H18O. separates, the yield in the course of two months being 67 p.c. of the pyrogallol used (Struve, A. 163, 160; De Clermont a. Chautard, C. R. 94. 103, 104; De Ciermont a. Chautard, C. A. 94, 1189, 1254). A solution of pyrogallol and Na,HPO, also yields pyrogalloquinone on exposure to air (Loew, J. pr. [2] 15,322). Purpurogallin forms C₂₀H_{1,2}Ac₂O, and C₂₀H_{1,2}Br₂O₂.—6. An ammoniacal solution exposed to the air forms brown pyrogallein C₁₈H₂₀N₂O₁₆ (Rösing, J. 1868, 250). 7 Ammoniacal content of 1302 forms 259).-7. Ammonium carbonate at 130° forms pyrogallol carboxylic acid C,H,O, (v. Tri-oxy-benzoic acid) and pyrogallol dicarboxylic acid C,H,O, [270°] (Senhofer a. Brünner, M. 1, 468). 8. Distillation over zinc-dust yields benz-

ene.—9. CICO₂Et acting on the K salt forms C₂H₂O₄ [105°] converted by aniline into diphenyl-urea and the mono-ethyl ether of pyrogallol (Bender, B. 13, 698).—10. A few drops of POCl, added to a mixture of pyrogallol (2 pts.) and acetone (1 pt.) react violently, forming gallacetonin C₉H₁₀O₃, which crystallises from 15 p.c. alcohol in whetstone-shaped crystals, insol. water, decomposing about 250°, and yielding C₀H₀AcO₂ (Wittenberg, J. pr. [2] 26, 76). Its solutions are turned purple by FeCl, and reduce AgNO3.-11. A few drops of H2SO, added to a mixture of pyrogallol (12 g.) and acetoacetic ether (8 g.) form di-oxy-methyl-coumarin $C_{10}H_3O_4$, which crystallises from water in needles [235°] and yields O₁₈H_AC₁O₄ [176°] (Wittenberg, J. pr. [2] 26, 68; Pechmann, B. 16, 2127; 17, 2188).—12. Phthalic aphydride forms, on heat-163; —12. Interest of the state needles (Snape, C. J. 47, 774). -14. Cyanogen passed into an aqueous solution forms C.H.O.Cy, or a polymeride thereof, as an unstable crystalnne pp. (Loew, J. pr. [2] 15, 326).—15. Chloroacetic acid (2\frac{1}{2} pts.) followed by NaOHAq forms $C_8H_1(O.CH_2CO_2H)_3$ crystallising in needles [198°], S. 1·3 at 14·5° and yielding K_2A''' and KH_2A''' aq (Giacosa, J. pr. [2] 19, 398).—16. Benzotrichloride at 160° yields 'pyrogallobenzein' $C_{38}H_{21}O_{11}$, crystallising in minute red plates with green lustre forming a blue solution. line pp. (Loew, J. pr. [2] 15, 326).—15. Chloroplates with green lustre forming a blue solution in alkalis and a bluish-violet solution in alcohol. Zinc and HOAc reduce it to the anhydride of hexa-oxy-diphenyl-methane. Pyrogallol-benzein yields $C_{38}H_{20}Ac_4O_{11}$ [208°], $C_{38}H_{20}Bz_4O_{11}$ [251°], $C_{38}H_{20}O_{11}(C_5H_5O)_4$ [228°] (Döbner a. Förster, A. 257, 60).-17. Benzoic acid and ZnCl, at 145° form tri-oxy-benzophenone (Alizarin yellow A) C₆H₂(OH)₃.CO.C₆H₅[141°], which crystallises with aq. The same body is got by heating pyrogallol with benzotrichloride (G. P. 50,451 [1889] and 54,661 [1890]; Graebe a. Eichengrün, A. 269, 297).—18. On heating pyrogallol with salicylic acid and zinc chloride tetra-oxy-benzophenone 28. Solution of the chiral straints and the chiral straints are chiral straints. 20. Benzene sulphonic chloride added to a solution of pyrogallol kept slightly alkaline forms $C_eH_a(O.SO_aPh)_a$ [142°], sol. alcohol, sl. sol. ether (Georgesen, B. 24, 418).—21. Formic aldehyde and dilute HClAq form CH₂(C₆H₂(OH)₂)₂₀ a microcrystalline powder, insol. water, sol. alcohol (Caro, B. 25, 947).-22. Aldehyde and dilute H2SO, mixed with Na2SO, added slowly at 60° gives colourless crystals of C,H,O, 2aq, which when dried at 30° over H,SO, leaves violet C₃H₂O₃ aq (Causse, Bl. [3] 3, 865; cf. Michael a. Ryder, Am. 9, 133).—23. Benzoio aldelyde and a large quantity of HClAq form amorphous C₂₄H₂₂O, (Baeyer, B. 5, 280). Benzoic aldehyde, alcohol, and a little conc. HClAq form and enque, according and a fitther of the distribution app. of $C_{2n}H_{2n}O_9$, which yields $C_{2n}H_{n}Ao_0O_9$ (Michael a. Ryder, Am. 9, 130). On heating with benzoic acid alone pyrogallol forms resinous $C_{2n}H_{2n}O_7$ and red $C_{2n}H_{10}O_7$, which may be reduced to colourless $C_{2n}H_{2n}O_7$ (Baeyer, B. 5, 25). 24. KOH (83 pts.) and $K_{2n}S_{2n}O_7$ (70 pts.) heated

with water (33 pts.) and pyrogallol (25 pts.) at 70° form C₆H₃(OH)₂(O.SO₃K), crystallising in needles, v. e. sol. water (Baumann, B. 11, 1913).—25. CICONH₂ forms $C_4H_4(O.CO.NH_2)$. [1786], crystallising from alcohol in plates.

Salts. - CaH3(OH)2(ONH1). Crystals, got by passing NH, into an ethereal solution of pyrogallol (De Luynes, A. Suppl. 6, 252).— C.H.(OH)(O.Pb) aq. Crystalline pp. got by adding lead nitrate to ammonium pyrogallol.

Converted by conc. NH₃Aq into C₆H₈O₃3PbO.— (C.H.O.)Pb.OAc. Ppd. by adding lead acetate to a solution of pyrogallol (Deering, C. J. 26, 702). -C_gH₃(SbO)O₃. Plates, got by ppg. pyrogallol solution with tartar-emetic (Rösing). SbCl₃ (100 g.) dissolved in a saturated solution (250 c.c.) of NaCl, filtered, and slowly added to pyrogallol (50 g.) dissolved in saturated NaClAq (250 g.), forms a white pp. which changes to crystals of C₈H₃(OH) SbOH 2aq, insol.water and alcohol, sol. mineral acids (Causse a. Bayard, Bl. [3] 7, 794). At 100° the above liquids on mixing yield C₆H₃O₃Sb, which is also crystalline, whence Ac2O at 100° forms C6H3O3Ac3. AcCl in Ac₂O converts both antimonites into C₈H₃(OAc)₃.—C₆H₆O₃2NPhH₂. [56°] (Mylius, B.

19, 1003). Acetyl derivative C.H. (OAc), Got from pyrogallol and AcCl (Nachbauer, A. 107, 244).

Benzoyl derivative C.H. (OBz). [90°]. Got, together with a mono- or di- benzoyl derivative [131.5°], from pyrogallol and BzCl (Skraup, M. 10, 391).

Di-mcthyl ether C.H. (OH) (OMe) .. [52° (253°). Occurs in beech-wood creosote (Hofmann, B. 11, 333; 12, 1373). Formed from pyrogallol (1 mol.), KOH, and MeI (2 mols.) at 160°. Prisms (from water). Its alkaline solution does not turn brown in air. Oxidised by means of K₂Cr₂O, and HOAc to corulignone C₁₂H₄O₄(OMe)₄. Yields C₄H₃(OAc)(OMe)₂ as a sticky mass, and C₄H₃(OBz)(OMe)₂ [118°].

Tri-methyl ether C₄H₃(OMe)₄. [47°].

(235°). Formed by the action of Mel and KOH on pyrogallol dissolved in MeOH (Will, B. 21, 607). Needles, insol. water and alkalis, v. sol. alcohol and other. Yields C, Br, (OMe), [81°]. Conc. HNO₃ forms $C_8H_2(NO_2)(OMe)_3$ [100°] and the di-methyl derivative of dioxyquinone.

Mono-ethyl ether C,H3(OH)2(OEt). [95°] Formed, together with the di- and tri-ethyl ethers, by heating pyrogallol with KOH and KEtSO, at 100° (Benedikt, B. 9, 125; M. 2, 212; Hofmann, B. 11, 797). Needles, m. sol. water,

normann, B. 11, 797). Needles, m. sol. water, v. e. sol. alcohol and ether. FeSO, gives a bluish-violet colour. Volatile with steam.

Diethyl ether C,H_(OH)(OEt), [79°]. (262°). Crystals (from dilute alcohol). Oxidised by K,Or,O, and HOAo to ethyl-cerulignone. Nitrous acid passed into an ethereal solution. forms C20H21O6HNO3, which forms a brown solution in water.

Tri-ethyl ether C_cH_s(OEt), [89°]. Got from pyrogallol, alcoholic potash, and EtI (Herzig a. Zeisel, M. 10, 151). Needles, insol.

Ethylens ether C.H.(OH):O2:C2H4. (267°). Formed from pyrogallol, alcoholic potash, and ethylene bromide (Magatti, B. 12, 1860). Yields O.H.(OBz):O.C.H. [109°].

References .- AMIDO-, BROMO-, CHLORO-, and NITEO- PYROGALLOL.

CARBOXYLIC PYROGALLOL ACID GALLIC ACID.

Pyrogallol dicarboxylic acid

C₈H(OH)₃(CO₂H)₂[1:2:3:4:5]. Gallocarboxylic acid. [270°]. S. 05 at 0°. H.C. 633,700. H.F. Gallocarboxulic 231,300 (Stohmann, J. pr. [2] 40, 128). Formed by heating pyrogallol or gallic acid with ammonium carbonate at 130° (Schhofer a. Brunner, M. 1, 468). Needles (containing 3aq), sl. sol. cold water. • Gives a violet colour with FeCl,... K,A" 2aq: needles. -- BaA"aq. -- CaA" 6aq. -- Ag_2A''

PYROGALLOL SULPHONIC ACID C.H.SO. i.e. C₆H₂(OH)₃,SO₃H ½aq. Formed by dissolving pyrogallol in H₂SO₄ (Personne, Bl. [2] 12, 169; 20, 531; Schiff, A. 178, 179). Hygroscopic crystals.—KA' 2aq: prisms, v. sol. water. Converted by heating with POCl₃ into C₁₂H₁₀S₂O₁₁, a flocculent mass, v. sol. alcohol, which is converted by warming with HOAc and Ac.O into crystalline C₁₂H,Ac₃S,O₁₁ and C₁₂H,Ac₃S,O₁₁.
PYROGALLOQU.NONE v. PYROGALLOL. Re-

action 5, and PURPUROGALLIN.

PYROGENTISIC ACID is HYDROQUINONE. PYROGLUTAMIC ACID is OXY-TETRA-METHENYL DIHYDRIDE CARBOXYLIC ACID.

PYROGLYCERIN v. DIGLYCERIN.

PYROGUAIACIN C18H18O3 i.e. C18H18O(OH)2 [180.5°]. (258°) at 80 90 mm. V.D. 9.53 (calc. 9.76). A product of the distillation of gum guaiacum (Pelletier a. Deville, C. R. 17, 1143; Ebermaier, J. pr. 62, 291; Nachbauer, A. 106, 382; Hlasiwetz, A. 106, 381; 119, 277; Wieser, M. 1, 594). Plates, v. sl. sol. hot water, sl. sol. alcohol and other. Forms a blue solution in H2SO4. On distillation with zinc-dust it yields guaiene C₁₂H₁₂ [100°], which is converted by oxidation into a lemon-yellow quinone C₁₂H₁₀O₂ [121°]. Potash-fusion forms C₁₂H₁₂O₂ [202°], which is reduced by zinc-dust to guaiene. Pyroguaiacin yields C₁₈H₁₈Ac₂O₃ [122°], C₁₈H₁₈Bz₂O₃ [179°], C₁₈H₁₈Br₃O₃ [172°], and the salt C₁₈H₁₆K₂O₃.

PYROLIC ACID v. SEBACIC ACID.

PYRO-MECAZONIC ACID C,H,NO,. Formed by heating oxycomenic acid, with NH,Aq and also, in small quantity, along with the isomeric amido-pyro-meconic acid, by the reduction of nitro-pyromeconic acid. Prepared from oxypyro-mecazonic acid by reducing with HI (Ost, J. pr. [2] 19, 203; 23, 441; 27, 258).

Properties .- Streaked trimetric tablets. Combines with mineral acids, but not with acetic acid. Gives rise to a di-acetyl derivative [155°] and a bromo-derivative C.H.BrNO. Is stable in acid solutions, but soon turns brown in alkaline solution. Gives a blue colour with FeCl. BaCl₂ and NH₂ give a pp. which turns bright blue in air.

Reactions .- 1. Suspended in ether and mixed with HNO, forms 'pyromecazone' C.H.NO. Pyromecazone is a brick-red powder, insol. ether, v. sol. water, gives no colour with FeCl., and turns the skin violet. With BaCl, and NH, it gives, on exposure to air, a crimson pp. Crystal-lises from alcohol as C₁H₂NO₂,EtOH. Aqueous SO₂ converts pyromecazone back into pyrome-cazonic acid. These properties resemble those

of a quinone.—2. Suspended in HOAc and

treated with HNO, it forms yellowish prisms of nitro-pyromecazone C,H_(NO_)NO, aq. This body is decomposed by water at 30° into nitro-pyro-mecazonic acid C,H_(NO_)NO, CO, coming off through oxidation of some of the substance. SO, rapidly changes nitro-pyromecazone into nitro-pyromecazonic acid, so that the former resembles quinone in its ready reducibility. Nitro-pyromecazonic acid gives a blood-red colour with FeCl3, nitro-pyromecazone gives no colour with FeCl3, It yields the salt C,H_NaN_O,.

Salt .- HA'HClaq: needles.

Oxypyromecazonic acid C₃H₂NO₄. Formed by passing SO₂ into an ethercal solution of nitrosopyromeconic acid, and boiling the product (v. Nitroso-Pyromeconic acid) with CHCl₂ (Ost, J. pr. [2] 19, 177). Needles (containing aq or 2aq). Coloured dirty-violet by FeCl₂.—NaHA'₂.—KHA'₂.—TlHA'₂.—CaA'₂.—HA'HCl.

PYROMECONIC ACID C₅H²₄O₃. [117°]. (225° uncor.).

Preparation.—By distillation of meconic acid in a current of CO₂, some comenic acid being also formed (Ost, J. pr. [2] 19, 182; 23, 441; cf. Robiquet, A. 5, 90; A. Ch. [2] 5, 282; 51, 236; Stenhouse, P. M. [3] 24, 128; A. 49, 18; F. D. Brown, P. M. [4] 4, 161; 8, 201; A. 84, 32; 92, 321; Ihlée, A. 188, 31). The yield is 14 p.c.

Properties.—Glittering prisms from water or alcohol. V. sol. chloroform, much less sol. ether. Gives a blood-red colour with FcCl., Feeble acid. Does not react with hydroxylamine (Oderheimer, B. 17, 2081). Bromine forms C₃H₃BrO₃, crystallising in prisms and yielding PbA'₂ aq. Excess of Br yields C₃H₃BrO₃ aq [100°]. ICl forms C₃H₃IO₃ yielding BaA'₂ aq and PbA'₄.

Salts.—Forms two sories of unstable salts, alkaline to litmus: KA'.—HNaA',.—BaA', 3aq.—BaH,a',.—CaH,a',.—CaH,a',.—MgA',.—SrA',aq.—PoA',.—CaH,a',.—CaH,Q,.;HCl. Formed by passing HCl into ethereal solution of the acid. Decomposed into its constituents by water or alcohol. Sulphates C,H,Q,H,SQ, and (C,H,Q,),H,SQ. Got by adding H,SQ, to an ethereal solution (Ost, J. pr. [2] 19, 189).

Acetyl derivative C,H3AcO3. [91°]. Obtained by warming with AcCl.

Nitroso-pyro-meconic acid $C_5H_1(NO)O_3$. An unstable compound of this body with an equivalent of pyro-meconic acid is formed by passing N_2O_3 into an ethereal solution of that acid (Ost, J. pr. [2] 19, 195). An aqueous solution of SO_2 converts this compound by addition of H_2 into $C_3H_1(NO)O_3, C_3H_4O_3$, a compound which is split up by boiling chloroform, leaving so-called oxy-mecaronic acid, $C_3H_3NO_4$. This acid gives a violet colour with FeCl₃, and a blue pp. with BaCl₂ and NH_3 . By Sn and HCl it is reduced to pyro-mecaronic acid $C_3H_3NO_2$.

References.—Amido- and Nitro-Pyromeconic

PYROMELLIC ACID C, H, O, [238°]. Obtained in the electrolysis of aqueous KOH with earbon electrodes, and got also by oxidation of mellogen by KOCI (Bartoli a. Papasogli, G. 12, 113; 13, 51). Crystalline (containing 2aq), sol. water and alcohol. Yields the crystalline salt C, H, Na, O, and an ethyl ether crystallising in golourless needles [below 100°], insol. water.

PYROMELLITIC ACID C₁₀H₁₀C₆ 4.6. C₈H₂(CO₂H)₄[1:2:4:5]. Mol. w. 254. [264°]. S. 14·2 at 16°. H.C.p. 777,400 (Stolmann, J. pr. [2] 40, 140; 43, 540). H.C.v. 778,900. H.F. 689,600. Formed by gently distilling mellitic acid (Erdmann, A. 80, 281) and by oxidising s-durene (Jacobsen, B. 17, 2517). Crystallises from water in triclinic tables (containing 2aq), v. sol. hot water. Forms various compounds on heating with (a)-naphihol (Grabowski, B. 4, 726; 6, 1065).—Ca.A'* 6aq.—Pb,A'*aq.—Ag,A'*: pp.

Methyl ether Me, A'r. [138°]. Plates, sl. sol. hot alcohol (Baeyer, A. 166, 339).

Ethyl ether Et.A. [53°]. Formed from the Ag salt and EtI (Baeyer, A. Suppl. 7, 36). Needles (from alcohol).

Chloride C.H. (COCI). Got by heating the acid with PCI. Crystalline mass, v. sol. ether.

Anhydride C₆H₂(C₂O₃). [268°]. Got by distilling the acid. Needles (by sublimation), v. sol. hot water, being re-converted into the acid.

Tetrahydride C₈H₈(CO₂H)₄. Formed by the action of sodium-amalgam on the ammonium salt of pyromellitic acid (Baeyer). Amorphous hygroscopic mass, v. sol. water. When heated with Π₂SO₄ it yields pyromellitic, trimellitic, and isophthalic acids.

Iso-tetrahydride C₈H_a(CO₂H)₄. [above 200°]. Accompanies the preceding acid. Needles (containing 2aq). Behaves like the preceding hydride when heated with H₂SO₄. Yields a methyl ether [156°] which may be distilled.

References.—Amido- and Nitro- Pyromel-

PYROMUCIC ACID C.H.O. i.e.

CH.CH. C.CO₂H. Furfurans (a)-carboxylic acid. Mol. w. 112. [132°]. S. 3·6 at 15°; 25 at 100°. R_{∞} 40·18 (in a 2·19 p.c. aqueous solution).

Formation.—1. By the distillation of mucic acid (Houton-Labillardière, A. Ch. [2] 9, 365; Pelouze, A. 9, 273; Boussingault, A. 15, 184; Liès-Bodart, A. 100, 327).—2. By distilling dehydromucic acid (Heinzelmann, A. 193, 184).—3. By oxidation of furfuraldehyde by Ag₂O (Schwanert, A. 114, 63; 116, 257).—4. Together with furfuryl-carbinol by boiling furfuraldehyde with alcoholic potash (Ulrich, Z. 1861, 186; Schmelz a. Beilstein, A. Suppl. 3, 275; Limpricht, A. 165, 279).—5. By distilling isosaccharic acid in a current of CO₂ (Tiemann a. Haarmann, B. 19, 1271).—6. Occurs, together with pyromycuric acid C,H,NO, [165°] which yields BaA'₂1½aq, in the urine of dogs dosed with furfuraldehyde (Jaffé a. Cohn, B. 20, 2311).

Preparation.—By oxidising furfuraldehyde with alkaline KMnO₄ below 20° (Volhard, A. 261, 379).

Properties.—Long white needles (by sublimation), v. sol. alcohol and ether. FeCl₃ gives no colour.

Reactions.—1. Bromine in excess forms mucobromic acid. Dry Br gives C₂H,Br,O₃ [160°], oxidised by dilute CrO₂ to di-bromopyromucic acid (Tönnies, B. 11, 1086).—2. Distillation with soda-lime yields furfurane.—3. On heating with lime and ammonia-zine-chloride it yields pyrrole.

Salts.—KA': needles.— NaA'.—BaA',: orys-

tals, sol. water and alcohol.—CaA'2: crystalline

powder.—CuA'₂ 3aq.—PbA'₂ 2aq.—AgA': scales. Ethylether EtA'. [34°]. (209°). Laminæ, v. sol. alcohol and ether, insol. water (Malaguti, A. 25, 276). Combines with dry chlorine, forming C.H.Cl.O. S.G. 195 1-496. Dry Br forms C.H.Br.O. [48°] (Tönnies) and also the ethers of $(\beta\delta)$ -di-bromo-pyromucic acid [167°], of $(\beta\gamma)$ di-bromo-pyromucic acid [192°] and of (δ)-bromopyromucic acid [192°] and of (δ)-bromopyromucic acid [183°] (Hill a. Sanger, A. 232, 65).

Chloride C₅H₃O₂Cl. (170°).

[1430]. Amide C,H,O.CONH, Formed from the ether or chloride and NH, Aq (Wallach, B. 14, 751; 214, 227; Ciamician a. Dennstedt, B. 14, 1058; G. 11, 291). Large plates, sol. alcohol, sl. sol. ether. Converted by PCl, or P.O. into the nitrile.

Ethylamide C.H.O.CONHEt. [258° cor.). Formed from pyromucic other and ethylamine solution at 100°. Converted by PCl, into crystalline C₁H₂O.CCl_{...}NHEt. PCl_. in smaller quantity (¹/₃ pt.) forms the amidine C₁H₂O.C(NEt).NHEt, a liquid (240°) which gives B'_{...}H_{...}PtCl_{...}

Anilide C,H,O.CO.NHPh. [123.5°]. Long needles (Schiff, B. 19, 849).

Nitrile C,H,O.CN. Furfuryl cyanide. (148°). Liquid with sweet taste, sl. sol. water, smelling like benzoic aldehyde. On reduction it gives C.H.O.CH..NH.

(B)-Pyromucic acid, got by oxidation of fucusol, is a mixture of pyromucic acid with methyl-pyromucic acid [108°] (Bicler a. Tollens,

A. 258, 126).

Isopyromucic acid. [82°]. Formed, together with pyromucic acid, in the distillation of mucic acid. It decomposes BaCO₃ very slowly, and can be separated by shaking the product with BaCO, and extracting with ether (Limpricht, A. 165, 256). Plates (by sublimation), v. e. sol. water, alcohol, and ether. FeCl₃ gives a green colour. Br yields mucobromic acid.

PYROMUCIC ALDEHYDE v. FURFURALDE-

PYROMYKURIC ACID C,H,NO, [165°]. Occurs in the urine of rabbits dosed with furfuraldehyde (Jaffé a. Cohn, B. 20, 2311). Prisms (from water). Split up by boiling baryta-water into glycocoll and pyromucic acid. -BaA', 1 aq: plates.—A urea compound (C,H,NO,)CO(NH,), [120°] occurs in the urine of dogs fed with meat. It crystallises from benzene in needles, v. sol. water and alcohol, sl. sol. ether, and is decomposed by heating with BaCO3 into urea and pyromykuric acid.

PYRONE. A name given to the ring co < CN:CH > 0.

PYROPHORUS. Any finely-divided substance which takes fire very easily when exposed to air is called a pyrophorus.

PYRORACEMIC ACID is PYRUVIC ACID. PYROTARTARIC ACID C.H.O. i.e. CO,H.CHMe.CH, CO,H.

Methyl-succinic acid. Mol. w. 182. [115°]. S. 66 at 20°. S.H. 3098 (from 0° to 50°) (Hess, A. Ch. [2] 85, 410). H.C.v. and p. 515,200

(Stohmann, J. pr. [2] 40, 209); 511,672 (Lou-guinine, C. R. 107, 597). H.F. 230,800 (S.).

Formation .- 1. By dry distillation of tartar (Valentin Rose, Gehlen's Journ. 3, 598) and of tartaric and racemic acids (Gruver, N. J. T. 24, 2, 55; Pelouze, A. Ch. [2] 56, 297; Weniselos, A. 15, 148; Fourcroy a. Vauquelin, A. Ch. 35, 161; 64, 42; Arppe, A. 66, 73).-2. By the reduction of ita-, citra-, and mesa- conic acids and of dibromopyrotartaric acid with sodiumamalgam (Kekulé, A. Suppl. 1, 342; 2, 95).-3. By saponifying its nitrile with HClAq (Maxwell Simpson, A. 121, 161). -4. By heating powdered tartaric acid with HClAq at 180° (Geuther a. Riemann, Z. [2] 5, 318).—5. By potash-fusion from gamboge (Hlasiwetz a. Barth, A. 138, 73).-6. By heating pyruvic acid alone at 170° or with HClAq at 100°, or by boiling it with baryta. 7. By boiling β-acetyl-α- or β- methyl-succinic ether with potash (Conrad, A. 188, 217; Kressner, A. 192, 135) .- 8. By heating allyl iodide (1 mol.) with KCy (2 mols.) and a little alcohol, and boiling the resulting nitrile with KOHAq (Claus, B. 5, 612; 8, 100; A. 491, 38). - 9. By heating propane tricarboxylic acid (Bischoff a. Guthzeit, B. 20, 614).-10. By oxidation of \$\beta\$. acetyl-n- and iso- butyric acid (Bischoff, A. 206,

Properties. - Trielinic prisms grouped like frog's feet (from ether), v. sol. water, alcohol, and ether. Begins to boil at 200°, yielding an anhydride together with some butyric acid (Claus, A. 191, 48). Its solution is not ppd. by lime-water or lead acetate, but gives a pp. with lead subacetate.

Reactions.-1. Bromine acts very slowly in the cold, but when the acid (10 pts.) is heated with Br (21 pts.) and water (10 pts.) at 120° for 6 hours bromocitraconic anhydride is formed (Lagermark, Z. 6, 299). When the acid (1 mol.) is heated with Br (4 mols.) at 132° acetylene tetrabromide is formed (Bourgoin, A. Ch. [5] 12, 419) .- 2. The K salt yields, on electrolysis, O, CO, and CO, at the positive pole (Reboul a. Bourgoin, C. R. 84, 1231).—3. Distillation with P₂S₄ yields methyl-thiophene.—4. On heating the acid (5 pts.) with resorcin (9 pts.) and ILSO, (18 pts.) at 150° there is formed pyrotartrylfluoresceïn C₁₇H₁₆O₈, a brownish-red powder, sl. sol. water, v. sol. dilute acids and alkalis. Its dilute alkaline solutions fluoresce yellowishgreen. It yields C17H12Br4O4 (Hjelt, B. 17, ĭ280).

Ethul ether EtA". (218° oor). 8.G.

Ethyl ether Et.A". (218° cor.). S.G. 15 10189; 25 10113. M.M. 9.347 at 17.4° (Perkin, C. J. 45, 516; cf. Malaguti, A. 25, 274).

Oktoride C.H.O.Ol. (190°-193°) (Hjelt, B. 16, 2624). Reduced in ethereal solution by sodium-amalgam and HOAc to liquid C, H,O,

(204°), S. 20, which is the anhydride of an acid $O_{\mu}H_{\nu}O_{\nu}$.

Anhydride $C_{\nu}H_{\nu}O_{\nu}$. (245° cor.) (Lebedeff, 4. 182, 327). Got by heating the acid at 200° alone or with $P_{\nu}O_{\nu}$. Heavy oil, slowly converted

by water into the acid.

CH_s.CH(CO.NH_s).CH_s.CONH_s. Amide [175°]. S. 7 at 10°. Large plates (Henry, C. R. 100, 943).

Imide CH, CH CO.NH. [66°]. Formed by heating acid ammonium pyrotartrate (Arppe, A. 87, 228). Six-sided trimetric plates, sol. water, alcohol, and ether.

Di-methylamide CaHa(CO.NHMe)2.

[115°] (Henry, Bl. [2] 43, 619).

Mono-anilide CO, H.CH., CHMe. CONHPh. [147°]. Formed from aniline and pyrotartaric anhydride in chloroform (Arppe, A. 90, 141; Anschütz, A. 246, 122). Got also by reducing the anilide of mesaconic acid with sodiumamalgam. Is identical with Reissert's 'pyranilpyroic lactone dihydride.' Bulky needles, m. sol. water.-PbA'2: white pp. -AgA'

Phenyl-imide CH₂.CH < CO .NPh. CH₂.CO (Arppe, A. 90, 139); [104°] (Biffi, A. 91, 105). Formed by heating the acid with aniline at 100° for ten minutes. Minute needles.

p-Nitro-anilide C₂H_e(CO₂H)(CO.NH.C₆H_eNO₂). [above 150°]. Formed by boiling the p-nitro-phenyl-imide with Na₂CO₂Aq. Minute tables, v. sl. sol. hot water. - AgA': white pp.

water.—AgA': white pp.
p-Nitro-phenyl-imide
C₂H₃:C₂O₂:NC₂H₃NO₂ [155°]. Formed by nicohol), almost insol. water.

p-Bromo-anilide C₂H₆(CO₂H).CO.NHC₆H₄Br. U₂H₄(CO₂H).CO.NHC₆H,Br. [158°]. Formed from the anhydride and p-bromo-aniline (Anschütz a. Hensel, A. 248, 269). Di-bromo-anilide

C₃H₆(CO₂H).CO.NHC₆H₃Br₂[1:2:4]. [139°]. Nitrile CH₃.CH(CN).CH₂CN. [c. [c. 12°]. (254°). Formed, amongst other products, by the action of KCN on allyl chloride (Pinner, B. 12, 2058). Prisms. Prepared from propylene bromide and alcoholic KCy at 100° (Maxwell Simpson, A. 121, 160). Liquid, sol. water, alcohol, and ether.

Ethyl ether of the seminitrile CO₂Et.CH₂.CHMe.CN. (198). S.G. 215 1.0275. V.D. 4.6. Formed from a-bromo-propionic ether and alcoholic KCy (Zelinsky, B. 21, 3162). Oil.

-NaA': very hygroscopic.

References.-Bromo-, Chloro-, Iodo-, Oxy-AMIDO-, and OXY- PYROTARTARIC ACID.

n-Pyrotartaric acid v. GLUTARIO ACID. Isopyrotartaric acid v. DI-METHYL-MALONIC

ACED. PYROTEREBIC ACID v. HEXENOIC ACID.

PYROTRITARIC ACID C,H,O, i.e. OCMe:CH Uvic acid. Di-methyl-furfurane carboxylic acid. Mol. w. 140. [135°]. S. 25 at 100°. A product of the distillation of tartaric acid (Wislicenus a. Stadnicki, A. 146,

806). Prepared by heating pyruvic acid with NaOAc and Ac₂O at 140°, the yield being 20 p.c. (Böttinger, B. 13, 1969; A. 172, 241; 208, 122; 247, 255), by heating pyruvic acid (30 g.) with dry sodium succinate (55 g.) at 110° (Fittig a. Parker, A. 267, 212), and by heating pyruvic acid (17.5 g.) with dry potassium propionate (20 g.) at 140° (Bischoff, B. 24, 2021). Formed also by heating methronic acid as long as CO, is given off (Fittig, A. 250, 190; cf. Harrow, C. J. 33, 425). Needles (from hot water), nearly insol. cold water, v. sol. alcohol and ether. affected by potash-fusion. PCl, gives a chloride, reconverted by water into the acid. Does not react with hydroxylamine or phenyl-hydrazine. Water at 160° forms acctonyl-acctone. By bromine it is converted into a tetra-bromoderivative and its tetra-bromide, which are both reduced back to pyrotritaric acid by sodiumamalgam. An excess of bromine at 100° forms penta-bromo-pyrotritario acid. By dry distillation it gives di-methyl-furfurane, a substance which is also obtained by distilling acetonylacetone with ZnCl₂ (Paal, B. 20, 1074; Dietrich a. Paal, B. 20, 1077).

Salts.—NaA' 2aq.—CaA', 2aq: prisms.— CaA', 4aq. — CaA', 6aq. — BaA', 4aq: plates.— BaA', 2aq. — BaA', 5aq. — ZnA, 8aq. – AgA'. Methyl ether MeA'. (192°). Got by dis-

tilling the Ag salt of carbopyrotritaric monomethyl ether (Knorr a. Cavallo, B. 22, 156).

Ethyl ether EtA'. (208° Pyrotritaric carboxylic acid v. METHRONIC ACID.

Carbopyrotritaric acid v. DI-METHYL-FUB-FURANC CARROXYLIC ACID.

PYROXANTHIN C15H12O2. [162°]. Extracted by NaOHAq from the product of the dry distillation of wood (Scanlan, J. pr. 7, 94; Gregory, A. 21, 143; Hill, Am. 3, 332; B. 11, 456). Orange needles (from alcohol), sol. benzene and HOAc. Forms a purple solution in H2SO4. Reduced by zinc-dust and HOAc to a colourless body. Bromine forms C15H10Br6O3 crystallising in small colourless triclinic needles, converted by alcohol and powdered Sb into C1.H10Br2O3, crystallising in yellow monoclinic needles, v. sol. hot alcohol.

PYROXYLIN v. CELLULOSE.

PYRRODIAZOLE C₂H₃N₂ i.e. N≪CH,NH [121°]. Formed by heating its carboxylic acid at 120° (Andreocci, B. 25, 229). Needles, v. e. sol. water and alcohol.

Pyrrodiazole carboxylic acid

CO₂H.C < N.NH. Formed by oxidising methylpyrrodiazole with alkaline KMnO4. White crystalline powder, v. sl. sol. water, alcohol, and ether.

PYRROLE C. H. N i.e. CH: CH NH. Pyrrhol. Pyrroline. Mol. w. 67. (130° i.V.). S.G. 1975 ·9752. S.V. 92·1 (Ramsay). H.F.p. 4,056 (Ramsay). Occurs among the products of distillation of coal (Runge, P. 31, 67) and of bones (Anderson, Tr. E. 20 [2] 247; 21 [4] 571; A. 80, 63; 105, 349).

Formation .- 1. By distilling ammonium mucate alone or with glycerin at 190° (Schwanert, A. 116, 279; Goldschmidt, Z. [2] 3, 280).—2. By heating its carboxylic scid.—8. By distilling succinimide with zinc-dust (Chichester Bell, B. 18, 877).-4. By distilling ammonium saccharate (Bell a. Lapper, B. 10, 1962).—5. By heating di-chloro-maleic imide with PCl, at 200°, and reducing the resulting perchloride C,Cl,N with zinc-dust and HOAc (Ciamician a. Silber, B. 17, 554; 19, 3027). The dichloro-maleïc imide may be got from succinimide and PCl. -6. By reducing tetra-iodo-pyrrole with zinc-dust and ROHAq (C. s. S.).—7. By heating albumen with Ba(OH)₂ at 150° (Schützenberger, Bl. [2] 25, 289).—8. By distilling pyromucic acid with ammonia-zinc chloride and CaO (Canzoneria. Oliveri, G. 16, 487).—9. By passing di-ethylamine through a red-hot tube (Bell, B. 10, 1868). 10. By passing ethyl-allyl-amine over PbO at 450° (Koenigs, B. 12, 2344).—11. By distilling glutamic acid (Haitinger, M. 3, 228).

Preparation.-Bone oil is shaken with acids and distilled. The fraction 98°-150° is heated with KOHAq and distilled, and the portion 125°-140° heated with solid KOH with inverted condenser. The solid C, H, NK thus obtained is washed with ether and decomposed by water, and the pyrrole distilled with steam (Ciamician, B. 13, 70; 19, 173; G. 16, 336).

Properties .- Oil with fragrant odour, resembling chloroform. Tastes hot and pungent. V. sol. alcohol and ether, insol. dilute alkalis. Turns brown in air. Turns pine-wood soaked in HClAq red. Dissolves in cold dilute acids, but on warming the solution pyrrole-red is formed as a bulky amorphous pp. FeCl, added to its solution in HClAq gives a green colour changing to black. Alcoholic HgCl₂ gives a white pp. Isatin and HOAc or dilute H₂SO₄ give a deep-blue pp. which forms a deep-blue solution in HOAc and H.SO, (V. Meyer, B. 16, 2974; Ciamician, B. 17, 142).

Reactions.—1. HNO, forms oxalic acid.—
2. Potassium acts very strongly, forming a colourless liquid, which solidifies on cooling to C.H.NK. Boiling with solid KOH gives the same body (Anderson, A. 105, 352). Sodium acts but slightly, forming C.H.NNa only at a very high temperature. NaOHAq has no action on pyrrole.—3. HCl passed into an ethereal solution ppts. crystalline (C,H,N),HCl, whence ammonia liberates an unstable base (Dennstedt a. Zimmermann, B. 21, 1478).-4. Hydroxylamine forms NH₃ and crystalline C₄H₈N₄O₂ [175°]. Converted by adding Na to its boiling alcoholic solution into tetramethylene-diamine (Ciamician, G. 14, 156; B. 22, 1968). The compound C,H,N2O2, when heated with phenyl-hydrazine, yields $C_{16}H_{18}N_{1}$, which crystallises from alcohol in plates [125°].—5. By a dilute solution of sodium hypochlorite (15 pts. of active chlorine in 1,000 pts. of water to 10 pts. of pyrrol) it is converted into di-chloro-maleic acid and chlorinated pyrroles. On the other hand, a concentrated solution of sodium hypochlorite (45 pts. of active chlorine in 500 pts. of water to 10 pts. of pyrrole) yields dichloro-acetic acid. An alkaline solution of bromine yields dibromomaleimide. Iodine in presence of alkalis yields tetra-iodo-pyrrol (Ciamician a. Silber, B. 17, 1743; 18, 1763).—6. Potassium pyrrole heated with ethyl iodide yields r-ethyl-pyrrole, di-ethyl-pyrrole C.H.Et:NEt, and probably also C.H.Et:NH. Potassium pyrrole and benzyl-chloride yield

v-benzyl-pyrrole (247°) (Ciamician, B. 22, 659; G. 17, 135).—7. Pyrrole (50 g.), boiled with par-G. 17, 135).—7. Pyrrole (50 g.), boiled with paraldehyde (50 g.) and ZnCl₂ (12 g.), forms oily ethyl-pyrrole C₂H₂N (164°) (Dennstedt a. Zimmermann, B. 19, 2189).—8. Pyrrole (1 pt.), acctone (10 pts.) and a drop of HCl give C₁₄H₁₈N₂ [291°), whence alcoholic AgNO₃ forms (C₁₄H₁₈N₂).AgNO₃, crystallising in needles (Baeyer, B. 19, 2184). The compound C₁H₁₂N₂ yields, on distillation, C₁₆H₁₂N (275°-285°), which is probably mesityl-pyrrole, and whence Ao₂O and NoOAc form resettly pyrrole. The compound NaOAc form v-acetyl-pyrrole. The compound C14H18N2, examined by Raoult's method, appears to have the formula C₂.H₁₀N₁. On heating pyrrole with acetone and ZnCl₂ isopropyl-pyrrole (174°) is formed. Among the products of the (174°) is formed. Among the products of the action of acctone on pyrrole there is also a yellow oil C₁₃H₁,N (?) (300°-305°), which soon blackens in air. This oil forms an acetyl derivative [above 360°], and is reduced by tin and alcoholic HCl to C₁₃H₁₁N (274°), which yields B'HCl [228°] and B'HSnCl, [170°] (Dennstedt a. Zimmermann, B. 20, 850, 2449; 23, 1870).— 9. Di-ethyl ketone, MeOH, and HCl give C₁₈H₂₆N₂ [210°], which yields B'_AgNO₃, crystallising in needles (Dennstedt a. Zimmermann, B. 20, 2455).-10. Chloroform converts potassium pyrrole into (β)-chloro-pyridine. Bromoform acts in like manner, giving bromo-pyridine. CH₂Cl₂ has no action, but CCl₄ forms chloropyridine, while benzylidene chloride yields (β)-phenyl-pyridine (Ciamician, B. 14, 1160; 15, 1172; 20, 191; G. 16, 140). - 11. Readily combines with diazo- compounds, forming azo- and disazo-Fischer a. Hepp, B. 19, 2251).—12. Pyrrole (5 g.) added to a lukewarm solution of alloxan (11 g.) in water (300 c.c.) forms colourless crystals of C₈H,N₂O₄ or NH₂.CO.NH.CO.CO.CO.O.Q.H₂NH, sl. sol. hot alcohol, nearly insol. water and ether, and yielding Ag₂A". Pyrrole-alloxan is converted by caustic potash solution into C,H_aN₂O₂ or NH₂CO.CO.CO.C₄H₃NH, which crystallises in white plates, v. sol. warm alcohol, and yields AgA' and crystalline MeA' (Ciamician, B. 17, 106, 1711; 19, 1708; G. 16, 198, 857).—

13. Pyrrole and MeOH distilled over zinc-dust yield (α)- and (β)- methyl-pyrrole, di-methyl-pyrrole, and di-methyl-dipyrrole (Dennstedt, B. 24, 2559).-14. Acetyl chloride, acting on potassium-pyrrole, forms v-acetyl-pyrrole and pyrryl methyl ketone (pseudo-acetyl-pyrrole), which may be separated by steam-distillation. Ac.O at 800° forms pyrrylene di-methyl diketone (Ciamician a. Silber, G. 15, 193). -15. Propionic anhydride and sodium propionate form, on boiling, v-propionylpyrrole, pyrryl ethyl ketone, and pyrrylene di-othyl diketone (Dennstedt a. Zimmermann, B. 20, 1760).—16. Bz₂O and NaOBz at 220° form pyrryl phenyl ketone (pseudo-benzoyl-pyrrole).

17. COCl, in benzene, added to C,H,NK in 17. COCl₂ in benzene, added to C₄H₄Na in ether, forms CO(NC, H₂), separating from ligroin in monoclinic crystals [63°] (238°) (Ciamician a. Magnaghi, B. 18, 415).—18. Phthalic anhydride and HOAc at 185° form C₁₂H₄NO, [241°], converted by Br into C₁₂H₃Pc,NO, [199°], and by boiling KOHAq into C₁₂H₃NO, [174°-184°], which yields McA' [105°] (Ciamician, B. 17, 2957;

The compound | Anderlini, B. 21, 2869). C12H, NO is reduced by water and Na to $C_4H_4N:C< \frac{O}{C_4H_4}>CH.OH$ [118°] (Ciamician, B.

19, 2206; 21, 1554).

Salts.-C.H.NK. Solid, absorbing CO, at 200°, forming pyrrole (β)-carboxylic acid.— B'2HgCl₂: crystalline powder, insol. water, sl. B'EHEOL; crystainne powder, mach mach sa sel. cold alcohol.—B',8CdCl,—B'ICl: black pp (Dittmar, B. 18, 1612).—Picrate: [c. 71°]; unstable (Hooker, B. 21, 3299).

Acctyl derivative C.H.NAc. (182° i.V.). Formed by the action of AcCl on potassiumpyrrole suspended in ether, and also as a byproduct in the preparation of pyrryl methyl ketone by heating pyrrole with Ac.N and NaOAc (Ciamician, B. 16, 2348; 18, 881). Oil, volatile with steam, saponified by hot KOHAq. Reddens acidified pine-wood. Gives a pp. with aqueous $\mathbf{HgCl}_{2}.$

C.H.N.COEt. Propionyl derivative (193°) (Dennstedt a. Zimmermann, B. 20, 1760).

Dihydride C.H.N. Pyrroline. (90° i.V.). Formed by reducing pyrrole with zinc-dust and HOAc (Ciamician a. Dennstedt, B. 16, 1536; 22, 2512; G. 15, 481). Hygroscopic liquid, v. sol. water. Yields a nitrosamine C,H,N(NO) sol. water. Yields a nitrosamine C,H,N(NO) [38°]. Absorbs CO₂ from the air.—B'HCl. [174°]. Flat prisms, v. sol. hot alcohol.—B',H,PtCl_a: triclinic crystals.—B'HAuCl, [152°].—B'C₆H₃N₃O₇. [156°]. Yellow crystals (from water). Benzoyl derivative C,H₈NBz. (160° at 2 mm.). Syrup, formed from the hydrochloride and BzCl at 110°. V. sol. alcohol.

Tetrahydride C,H₃N. Pyrrolidine. (38.5°). S.G. 225° -8520. Formed by reducing the dihydride by HIAq at P at 250° (Ciamician a. Macnaghi, G. 15. 483; B. 18, 2079). Formed

a. Magnaghi, G. 15, 483; B. 18, 2079). Formed also, together with tetra-methylene-diamine, by the action of Na on ethylene cyanide or succinimide in alcohol, and by distilling tetramethylenediamine hydrochloride (Ladenburg, B. 19, 782; 20,442,2215; Petersen, B. 21, 290). Formed from chlorobutylamine hydrochloride and KOHAq (Gabriel, B. 24, 3234). Liquid, with pungent ammoniacal odour. Yields a liquid nitrosamine (214°), v. sol. water.—B',H_l'rtCl_g. [200°]. Prisms.— B'HAuCl, [200°].—B'C₆H,N₄O, [112°].—B'₄H₂Bi,I₉.—B'H₂CdI, [219°]. Needles. **Pyrrole red** Cl₁₂H₄N₄O, Formed by boiling

pyrrole or its carboxylic acid with dilute H2SO4 or HCl (Anderson, A. 105, 357; Schwanert, A. 116, 280). Reddish-brown flakes, insol. water, ether, acids, and alkalis, sl. sol. alcohol. Yields

pyrrole on distillation.

Homopyrrole v. METHYL-PYRROLE.

References .- BROMO-, CHLORO-, IODO, NITRO-, and Oxy-AMIDO- PYRROLE.

PYRROLE - AZO- v. Azo- compounds and DISAZO- COMPOUNDS.

PYRROL-CARBO-KETONIC ACID v. PYRRYL-

GLYOXYLIC ACID. PYRROLE (a)-CARBOXYLIC ACID C.H.NO.

i.e. C.H. (CO.H.) NH. Carbopyrrolic acid. [1919].

Formation.—1. By the action of boiling baryta on its amide, which is got by distilling ammonium mucate (Malaguti, A. 15, 179; Schwanert, A.116, 270; Ciamician, B.17, 1, 1, 1).— 2. By boiling pyrocoll with KOHAq (Weidel a. Ciamician, M. 1, 285).—3. By fusing potassium (a)-methyl-pyrrole with potash (Ciamician, B.

14, 1054; G. 11, 228).-4. By heating pyrrole with ammonium carbonate and water at 140° (Ciamician a. Silber, B. 17, 1150; G. 14, 162).-5. By heating pyrrole with alcoholic potash and CCl. (Ciamician a. Silber, B. 17, 1437).—6. By the action of CO₂ on potassium pyrrole at a high temperature (C. a S.).

Properties.-Prisms (from water), sol. water and alcohol. Decomposed by heat into CO, and pyrrole. HClAq forms, on warming, CO2, pyrrole

red, and NH₂Aq.
Salts.—NH₁A': m. sol. water.—CaA'₂: scales.—BaA'₂ (dried at 100°): 'plates, sol. water and alcohol.—PbA'₂: nacreous scales, v. sol. water.—AgA': small needles, sl. sol. water.

Methyl ether Med. [173°]. Prisms. Ethyl ether Eth. [39] (231°). Amide C.H. (CONH.)N. [173°]. Lamins. v. sol. alcohol and ether, m. sol. water.

Acetyl derivative C,H,N.CO.OAc. [75°]. Formed from the Ag salt and AcCl. Scales, readily decomposed by water into acetic acid and pyrrole carboxylic acid. At 75° it decom-

poses into HOAc and pyrocoll.

Pyrrole (β)-carboxylic acid C,H,(CO,H):NH. • [162°]. Formed by fusing potassium (β)-methylpyrrole with potash (Ciamician, B. 14, 1054). Needles, partially decomposed by boiling water into CO, and pyrrole. The lead salt is sl. sol. water.—BaA'2: needles. A pyrrole carboxylic acid [166°], got by potash-fusion from isopropylpyrrole, and yielding a methyl ether [129°] (Dennstedt a. Zimmermann, B. 20, 855), is probably identical with the (B)- acid.

Pyrrole v-carboxylic acid

Ethyl ether C,H,N.CO.Et. Tetrol-thane. (180°). Formed from potassiumurethane. (180°). pyrrole and ClCO_Et in ether (Ciamician a. Dennstedt, G. 12, 84). Oil.

Amide C.H.N.CONH2. [167°].

from the ether and NH₃.

Nitrile C₄H₄N.CN. Tetrol cyanuramide. [210]. Got by passing CyCl into potassium-pyrrole in ether (Ciamician a. Dennstedt, G. 13, 102). Needles, insol. water, sol. hot alcohol. Boiling alcoholic potash forms pyrrole, CO, and

Pyrrole dicarboxylic acid C.H.NO. i.e. C4H2(CO2H)2NH. Formed by oxidising pyrrylene dimethyl diketone, and fusing the product with potash (Ciamician a. Silber, G. 16, 377; B. 19, 1958; 20, 2601). Needles (from dilute alcohol), sol. ether and hot water. Blackens at 260°, giving pyrrole and CO₂. FeCl₃ gives a brown pp. The Ba salt crystallises in needles. The Ag salt is a curdy pp.

Mono-methyl ether MeHA". [243°].

Di-methyl ether Me₂A". [132°]. Di-ethyl ether Et₂A". [82°].

References .- Bromo-, Chloro, and Nitro-PYRROLE CARBOXYLIC ACIDS.

PYRROLINE. A name used both for Pyrrole and Pyrrole DIHYDRIDE.

PYRROLYLENE v. BUTINENE.

PYRROLYLENE TETRABROMIDE v. Tetra-BROMO-BUTANE

PYRRONE v. DI-PYRRYL-KETONE.

PYRROYL-FORMIC ACID v. PYRBYL-GLY-

PYRROYL - PYRROL C4H4N.CO.C1H3NH [63°]. Formed, together with di-pyrryl-ketone

CO(C.H.NH), by intramolecular transformation of carbonyl-pyrrole by heating it to 250° for a few hours (Ciamician a. Magnaghi B. 18, 1829). White silky plates. Not volatile with steam. By heating with aqueous KOH it is split up into pyrrole and pyrrole-(a)-carboxylic acid.
PYRROYL-PYRUVIC ACID. Ethyl ether

C.H.,NH.CO.CH.,CO.CO.Et. [128°]. Formed by the action of NaOEt and oxalic ether on pyrryl methyl ketone (Angeli, B. 23, 1794, 2155). Yellowish plates, v. sol. alcohol, sl. sol. water. Decomposed by alkalis, even in the cold, into oxalic acid and pyrryl methyl ketone. Hydroxylamine forms $C_{10}H_{10}N_2O_3$ [124°], which on saponification yields the acid CH CH.N.N:C.CO.CH. [179°], crystallising in white needles. Aniline (2 pts.) caystantising in whice needles. Annihe (2 pts.) in HOAc forms $C_4H_3NH.CO.CH_2.C(NPh).CO.Et$ [115°]. Phenyl-hydrazine forms $C_1_6H_{15}N_3O_2$ [168°] which is the ether of an acid [215°].

Anhydride CH CH.C.CO.CH₂ [250°]: Formed by adding HCl to the mother-liquor from which the ether has separated (Angeli, B. 23, •1795). Yellow needles (from benzene), v. sol. alcohol. o-Phenylene-diamine forms C.H.N.O. a reddish-yellow crystalline powder forming a bluish-green solution in H₂SO₄ and yielding a benzoyl derivative [c. 166°]. Aniline forms C4H4N CO.CNPh [218°], whence cold KOHAq forms an acid C₁₄H₁₂N₂O₃ [179°].

PYRRYLENE DIETHYL DIKETONE C.H.NH(COEt)2. [117°]. Formed by heating pyrrole with propionic anhydride at 260° (Dennstedt a. Zimmermann, B. 20, 1761). Plates.

PYRRYLENE DI-METHYL DIKETONE

C,H,NO, i.e. NH CAc:CH. [162°]. by heating pyrrole, pyrryl methyl ketone, or acetyl-pyrrole with Ac2O at 250° (Ciamician, B. 17, 432, 2953; 18, 881, 1466; 19, 1957; 20, 2595). Needles, sol. hot water and hot KOHAq. May be sublimed. Yields a nitro-derivative [149°] and a di-bromo-derivative [172°].- AgA'.

PYRRYLENE DISTYRYL DIKETONE (C₆H₃.CH:CH.CO)₂C₄H₂NH. [240°]. Formed by heating pyrrylene dimethyl diketone with benzoic aldehyde and KOHAq (Ciamician a. Denn-Stedt, B. 17, 2953). Crystals (from HOAc), sl. sol. alcohol. Forms a violet solution in H₂SO₄.

PYRRYL ETHYL KETONE C, H, NO i.e. C2H3.CO.C4H3NH. [52°]. (224°). Formed by boiling pyrrole with propionic anhydride and sodium propionate (Dennstedt a. Zimmermann, B. 20, 1761). Colourless needles.—AgA': pp.

PYRRYL-GLYOXYLIC ACID C.H., NO, aq i.e. C,H,NH.CO.CO,H aq or C,H,NH.C(OH),CO,H. Formed by oxidation of pyrryl methyl ketone by KMnO, (Ciamician a. Dennstedt, B. 16, 2350; 17, 2949). Crystallises from benzene in yellow needles (of C,H,NO4) melting at 76°, v. sol. hot water. After drying over sulphuric acid the acid (C,H,NO) decomposes at 114°. The aqueous solution gives a red colour with FeCl. On heating with HClAq it gives a crimson colour turned yellowish-green by alkalis .-- AgA': colourless needles, sol. hot water.

Methyl ether MeA'. [72°]. (285°). Monoclinic crystals, sl. sol. water.

Carboxy-pyrryl-glyoxylic acid CO₂H.C, H₂NH.CO.CO₂H. Formed by oxidation of pyrrylene dimethyl diketone (Ciamician a. Silber, B. 19, 1412, 1961). Crystalline, v. sol. Methyl ether Me₂A". [145°].

DI-PYRRYL KETONE CO(C₁H₃NH)₂. [160°].

Formed, together with (C,H,N)₂CO, by the action of COCl₂ on C,H,NK. Formed also, together with pyrroyl-pyrrole, by heating (C,H,N)₂CO at 250° for a few hours (Ciamician a. Magnaghi, B. 18, 414, 1829). Trimetric crystals; a:b:c=2.531:1:2.901. V.sol.alcohol, ether, and benzene, nearly insol. water. Ag,A": yellow pp.

PYRRYL METHYL KETONE C,H,NO i.e.

CH₃.CO.C₄H₃NH or NH < CAc:CH CH:CH acetyl-pyrrole. [90°]. (220° uncor.). V.D. 3.8 (calc. 3.8). Formed by boiling pyrrole with Ac.O and NaOAc (R. Schiff, B. 10, 1501; Ciamician a. Dennstedt, B. 16, 2348; 17, 432, 2944; 18, 1456; 20, 2605; G. 15, 175). Formed also by heating pyrrole with Ac₂O and ZnCl₂ (Dennstedt a. Zimmermann, B. 19, 2204), and by heating CH₃.CO.C₄H₃N.CO₂K with K₂CO₃ at 290° (Ciamician a. Silber, B. 19, 1963). Long monoclinic needles, sol. hot water, v. sol. aqueous alkalis, sparingly volatile with steam. Not converted into pyrrole and KOAc by potash.

Reactions.—1. Yields pyrryl-glyoxylic acid when oxidised by KMnO,—2. Benzoic aldehyde and dilute KOH form pyrryl styryl ketone. - 3. Water and sodium-amalgam reduce it to crystalline pyrryl methyl pinacone $C_{12}H_{16}N_2O_2[120^\circ]$ and pyrryl-methyl-carbinol CH_3 , CH(OH), C_4H_3NH Pyrryl-methyl-pinacone an oil (290°-300°). C,H,N.CMe(OH).CMe(OH).C,H,N crystallises in prisms (containing 2aq) melting at 98° when hydrated .- 4. Oxalic ether and NaOEt form pyrroyl-pyruvic ether (Angel, B. 23, 1357, 1794). 5. Cold furning H.SO, yields an unstable sulphonic acid, which forms a crystalline K salt.

Salt.—C₁H₃AcNAg. Crystalline pp.

OximCH₃.C(NOH).C₁H₃NH. [146°]. Needles. Phenyl-hydrazide

CII, C(N.HPh). Q.H, NH. [147°]. White powder. References.—Amido., Bromo., Bromo.nitro., and NITRO- PYRRYL METHYL KETONE.

PYRRYL METHYL KETONE CARBOXYLIC ACID C,H,NO, i.e. CH, CO.C,H,N.CO,H. [186°]. Formed by saponification of its methyl ether, obtained by heating methyl pyrrole (a)-carboxylate with Ac.O at 260° (Ciamician a. Silber, G. 14, 169; B. 17, 1155). Leaflets, sol. water, alcohol, and ether. FeCl, gives a brown pp .-CaA'₂7aq: triclinic prisms.—*PbA'₂: needles.—AgA': powder, sl. sol. water.

AgA': powder, st. sol. water.

Methyl ether MeA'. [113°]. Gives with
ammoniacal AgNO, a pp. C.H.,AgNO.

PYRRYL PHENYL KETONE C.,H.,NO i.s.

C.H.,CO.C.H.,NH. [78°]. Formed by heating pyrrole with benzoic anhydride and dry NaOBz at 200°-240° (Ciamician a. Dennstedt, B. 17,

at 200°–220° (Ciamician a. Dennstedt, B. 17, 432, 2955). Needles, v. sol. alcohol, sl. sol. hot water.—C₁₁H₂AgNO.

FYRRYL STYRYL KETONE C₁₂H₁₁NO i.e.
C₃H₂,CH:CH.CO.C,H₂NH. [142°]. Formed by obling pyrryl methyl ketone with C₂H₃CHO and KOHAq (Ciamician a. Dennstedt, B. 17, 2947). Yellow needles, sl. sol. alcohol, insol. water .-C₁₈H₁₀ONAg: yellow needles, insol. NH₂Aq.

PYRUVIC ACID C.H.O. i.s. CH., CO.CO.H. Pyroracemic acid. Di-oxy-propionic acid. Mol. w. 88. [9°]. (c. 165°). S.G. 18 1-2752; 28 1-2700. M.M. 3-557 (Perkin, C. J. 61, 836).

Formation.—1. By distilling racemic or tartaric acid (Berzelius, A. 13, 61; Völckel, A. 89, 65; Wislicenus, A. 126, 225).—2. By gradually heating tartaric acid with HClAq in sealed tubes to 180° (Geuther a. Riemann, Z. [2] 5, 318).—3. By heating tartaric acid with conc. H₂SO₄ at 40°–50° (Bouchardat, C. R. 89, 99).—4. By heating silver di-a-chloro-propionate with water (Beckurts a. Otto, B. 10, 265; 18, 227).—5. By distilling glyceric acid (Moldenhauer, A. 131, 338; Böttinger, A. 196, 92).—6. By boiling acetyl cyanide with dilute HCl (Claisen a. Shadwell, B. 11, 1563).—7. By oxidation of a cold aqueous solution of calcium lactate by KMnO₄ (Beilstein a. Wiegand, B. 17, 840).

Preparation.—1. Tartaric acid (3 lbs.) is distilled from a glass retort (30 lbs. capacity). The distillation takes three hours. A fresh quantity of tartaric acid is then added and the operation repeated. The distillate is fractionally distilled (Clewing, J. pr. [2] 17, 243).—2. Dried, and finely powdered, tartaric acid is mixed with an equal weight of sand and distilled (Seissl, A. 249, 297).

8. Tartaric acid is distilled with KHSO₄, the yield being 50 to 60 p.c. (Erlenmeyer, B. 14,

321).

Properties.—Liquid, smelling like acetic acid, v. e. sol. water, alcohol, and ether. Colourless crystals below 9° (Simon, Bl. [3] 9, 111). Partially decomposed on distillation. Reduces ammoniacal AgNO₂, forming a mirror, and yielding CO₂ and acetic acid. Coloured cherry-red by alkaline sodium-nitroprusside, the colour being discharged by HOAc (Von Bitto, A. 267, 377). Readily ppd. by phenyl-hydrazine. Forms an

Reactions.—1. Dilute H.SO, at 150° splits it up into aldehyde and CO₂ (B. a. W.).—2. By long heating at 170° it is converted into CO₂ and acetic, pyrotartaric, uvic, and citraconic acids (Böttinger, B. 9, 670, 837, 1823).—3. HClAq at 100° forms CO, and pyrotartaric acids (De Clermont, B. 6, 72).—4. Boiling with Ag₂O yields CO₂ and acetic acid.—5. Reduced to lactic acid by sodium-amalgam, and by Zn and H.SO,.— 6. HI reduces it to propionic acid.—7. Zinc when added to its alcoholic solution forms CO2H.CMc(OH).CMc(OH).CO2H (Böttinger, B. 9, 1064) .- 8. PCl, forms di-a-chloro-propionic acid (Klimenko, B. 3, 465; Beckurts a. Otto, B. 11, 386) .- 9. Dry bromine at 0° forms crystalline di-bromo-lactic acid (?). Br and water give di-bromo-pyruvic acid (Wislicenus, A. 148, 208; Wichelhaus, A. 152, 265).—10. Oxidised by chromic acid mixture to CO₂ and acetic acid.—11. HNO forms oxalic acid and CO₂.—12. Boiling baryta-water forms uvitic, uvic, pyrotartaric, oxalic, and acetic acids and CO, (Fincht, A. 122, 182; Böttinger, B. 8, 957; A. 172, 241, 253; 188, 313; 208, 129). Baryta-water added to a cold solution of pyruvic acid ppts. barium hydruvate BaC.H.O., or the basic salt Ba.H.(C.H.O.). Hydruvic acid is a syrup.— 18. On heating with excess of quickline it yields a little aldehyde (Hanriot, C. R. 101, 1156; Bl. [2] 45, 81).—14. HCN followed by HCl forms lactic soid. KCN followed by HCl yields

ACID. On warming pyruvic acid with HON under pressure the product is CMe(NH,)(CO,H), crystallising in unstable prisms (Körner a. Menozzi, G. 17, 104).—15. Alcoholic ammonia forms methyl - pyridine dicarboxylic acid.-16. Aniline added to an ethereal solution forms C₉H₉NO₂, i.e. CH₃.C(NPh).CO₂H [122°] (Böttinger, B. 10, 818). Aniline alone forms, on heating, C.,H.,N.20, crystallising from dilute alcohol in needles [195°], while p-toluidine gives C., H.,N.20 [238°] (Lazarus, B. 17, 998). Antline and furfuraldehyde form C.,H.,C.H. C.C.,H.)C, crystallising in greenish-yellow needles [210°-215°] (Doebner, A. 242, 285). Tetra-amido-anisole forms the quinoxaline C₈H(OMe)(N₂C₃H₄O)₂ as orange-vellow flakes, v. sol. alkalis (Nietzki a. Kurtenacker, B. 25, 284).—17. H,S passed into water containing the Agsalt forms thiolactic acid (Böttinger, B. 9, 404; Loven, J. pr. [2] 29, 376).—18. PH₂ and HCl passed into an ethereal solution form 'phosphortrianhydropyruvic' acid C.H.PO., crystallising in needles, insol. alcohol and ether, and forming with phenyl-hydrazine the compounds forming with pnenyl-nydrazine the compounds $C_bH_1PO_3PhN_1H_1$ [132°] and $C_bH_bN_1O_4$ (7) [162°]. The acid $C_bH_bPO_g$ is converted by aniline into $C_aH_aN_1PO_4$ [158°], whence phenyl-hydrazine forms $C_aH_aN_2O_4$ [169°]. Tolylene-diamine converts $C_bH_aPO_g$ into $C_bH_aPO_g$ (7), [178°] (Messinger a. Engels, B. 21, 334, 2919).—19. Pyruvio acid (50 g.) heated with dry sodium succinate (92 g.) and Ac.O (58g.) at 110° forms di-methyl-maleïc anhydride (pyrocinchonic anhydride) (Fittig a. Parker, A. 267, 204). Pyruvic acid (30g.) heated with dry sodium succinate (55 g.) at 110° forms uvic (pyrotritaric) acid.—20. Pyruvic acid (30g.) heated with sodium pyrotartrate (60 g.) and AcO (36g.) at 140° forms methyl-ethyl-maleic anhydride (F. a. P.) .- 21. Benzonitrile and cold anhydride [F. a. F.].—21. Benzontrite and courty-SO₄ form an acid C_{1,1}H_{1,6}N₂O₄ crystallising in tables [172°], insol. water, v. sol. acetone (Böttinger, B. 14, 1599).—22. Phenyl-acetonitrile and H₂SO₄ form, in like manner, C₁₀H₂₀N₂O₄ [145°] (B.).—23. By heating with aldehydes R.CHO and baryta-water it is considered in the solution of the form verted into s-alkyl-isophthalic acids of the form C₂H₂R(CO₂H)₂(Doebner, B. 23, 2378).—24. Benzoic aldehyde and aniline in ether form, in the cold, C22H18N2O or CHPh:CH.C(NPh).CONHPh [225°], insol. water, acids, and alkalis, sl. sol alcohol and ether. Cuminic aldehyde and aniline give C_uH_{z1}N₂O [216°] (Doebner a. Giesoke, A. 242, 290; 249, 102). Benzoic aldehyde and p-toluidine form, in like manner, C2.H2N2O [205°].-25. Isobutyric aldehyde and aniline in alcoholic solution react forming CHPr.CH.C(NPh).CONHPh (?) [222°] crystallising from HOAc in needles, while isovaleric aldehyde and aniline in ether give C20H21N2O [160] (Doebner, A. 242, 275). Isovaleric aldehyde in warm alcoholic solution forms the acid C.H.NO. —26. Thioglycollic acid gives rise to CO.H.CMe(OH).S.CH.CO.H [110°] with evolution of heat; while HCl passed through a mixture of pyruvic and thioglycollic acids produces CO₂H.CMe(S.CH₂CO₂H)₂ [162°] crystallising from ether (Bongartz, B. 19, 1933; 21, 484).—27. Phenyl mercaptan forms the compound CH₂C(SPh)(OH).CO₂H, while p-bromo-phenyl mercaptan forms CH₂C(SO₂H₄Br)(OH).CO₂H

CH, C(OH)(CN).CO,H v. GYANO-OXY-PROPIONIC

[114.5°] (Baumann, B. 18, 263).-28. Ethylene mercaptan forms a substance [96°] which crystallises from benzene as a fine powder, and may be

condensed to CH₂.S CMe.CO₂H [102°], which

on oxidation gives ethylene ethylidene disulphone [198°] (Fasbender, B. 21, 1473).—29. Benzene and H.SO, form CH, CPh, CO, H, while phenol and H.SO, yield C₁₈H₁₁O₄ (Böttinger, B. 14, 1595; 16, 2071).—30. Distillation of the K salt with KOAc forms acetone and pyrotartaric acid (Wichelhaus, Z.[2] 5, 254).—31. Pyruvic acid (1 pt.) heated with urca (2 pts.) at 100° forms pyvuril or 'pyruvic diureide 'C₃H₈N₄O₃, which crystallises in tables, S. 10 at 100°, insol. alcohol and ether in tables, S. 10 at 100°, insol. atcord and eater (Grimaux, C. R. 79, 526, 1304, 1478; 80, 53; A. Ch. [5] 11, 373). Pyvuril is decomposed by long heating at 160°, forming amorphous 'tetrapyruvic tetraureido' C₁₈H₁₈N₈O₈, insol. water. Boiling dilute HClAq converts pyvuril into urea and 'dipyruvic triureido' C₂H₁₂N₈O₃, which crystallises from hot water in needles, S. 4 at \$\frac{1}{2}\text{Coll}_{2}\text{Lownward}\$ by beiling allelis into urea 100°, decomposed by boiling alkalis into urea, pyruvic acid, and pyvuril. Boiling conc. HClAq converts pyvuril into urea and 'pyruvic ureido

 $C_{_4}\mathrm{H}_{_4}\mathrm{N}_{_2}O_{_2}$ or $CO{<}^\mathrm{N}_\mathrm{NH,CO}^\mathrm{M=CMe}$,

powder, m. sol. hot water, insol. alcohol. Nitric acid converts pyvuril into nitro-pyruvic ureide C,H3(NO2)N2O2 [above 200°], which is decomposed by boiling bromine-water into parabanic acid and CBr. NO2. Pyruvic acid heated with an equal weight of urea at 100° forms amorphous insoluble 'tripyruvic tetraureide' C13H16N8O, and dipyruvic triureide .- 32. Sodium hippurate and Acoo at 100° form the dibasic acid C12H2NO4 [157°] (A. Hoffmann, B. 19, 2555).-33. solution of indoxyl forms on adding conc. HCl

the indogenide $C_9H_4 < \stackrel{CO}{\sim} > C:CMe.CO_2H$ [197°],

crystallising in red needles forming a blue solution in H.SO, (Baeyer, B. 16, 2199).-34. Glycerin and KHSO, form 'glycuvic acid,' or 'pyruvin,' which is also got by heating glycerin with glyceric acid at 120°, and by distilling glycerin with citric acid. Glycuvic acid is probably

 CH_3 .CO.CO.O.CH₂.CH< $\stackrel{C}{O}$. It is crystalline [82°] (241°), and yields pyruvic acid when boiled with baryta (Böttinger, B. 10, 286; 14, 316; A. 263, 246; Jowanovitch, M. 6, 467; Erhardt, M. 6, 511; Schlagdenhauffen, C. R. 74, 672; De

Clermont, C. R. 105, 520).

Salts.-The salts crystallise well, provided heat is avoided in their preparation; otherwise they become amorphous. The acid also is changed by evaporation of its aqueous solution into a non-volatile syrupy mass.—NaA': large prisms.—BaA', aq: scales.—BaA', 2aq: amorphous.-PbA'2 aq: crystalline pp.-ZnA'2 3aq: white microcrystalline powder, sl. sol. water (Beckurts a. Otto, B. 18, 227).—CuA'₂ aq.—AgA': scales, sl. sol. water.

Combinations with bisulphites (Clewing, J. pr. [2] 17, 241).—HA'NaHSO, aq: orystals. NaA'NaHSO, aq. — NaA'NaHSO, 1 2 aq. HA'KHSO₂; aq. — MAN MARSO₃ 1₃84. — HA'KHSO₃ cotahedra. — KA'KHSO₃ aq. — CaA'₂0a(HSO₃)₂ 3aq. — (CaA'₂)₄(Ca(HSO₃)₂)₂ 24aq. — (CaA'₂)₄(Ca(HSO₃)₂)₂ 3aq. — SrA'₂Sr(HSO₃)₂ 5aq. — BaA'₂Ba(HSO₃)₂.

Vol. IV.

Methyl ether MeA'. (c. 136°). S.G. 9 1.154. Got from AgA' and MeI.

Ethyl ether EtA'. Oil. Converted by aniline into two crystalline bodies [144°] and [c. 250°]. The compound O(CMe(OH).CO,Et)2, formed by the action of nitrous acid on amidopropionic ether, is an oil (80°-86° at 120 mm.) (Curtius, J. pr. [2] 38, 472).

Isoamyl ether C,H,A'. Got by distilling the acid with isoamyl alcohol (Simon, Bl. [3] 9,

Amide CH₃.CO.CO.NH₂. [125°]. Got from acetyl cyanide and HCl (Claisen a. Shadwell, B. 11, 1566). Prisms or tables (from alcohol).

Nitrile v. ACETYL CYANIDE.

Phenyl hydrazide CH3.C(N2HPh).CO2H. [192°] (F.); [185°] (Japp a. Klingemann, B. 20, 3284; A. 247, 208; C. J. 53, 519). Ppd. when a solution of phenyl-hydrazine hydrochloride is added to a dilute seven 1 in 1000) solution of pyruvic acid (Fischer, B. 16, 2241; 17, 578). Prisms, sol. hot water and hot alcohol. Reduced by sodium-amalgam to phenyl-hydrazido-propionic acid [172°]. At 190° it gives off CO, and H., and forms the phenyl-hydrazide of di-methyl diketone [242°] and the oily phenyl-hydrazide of aldehyde. The ether CH3.C(N2HPh).CO.Et[117°], crystallises in yellow needles (from ligroin).

o-Chloro-phenyl-hydrazide C₆H₄Cl.NH.N:CMc.CO₂H. [178°]. Lemon-yellow needles, forming a crystalline ethyl ether [168°] (Hewett, C. J. 59, 211).

p-Nitro-phenyl-hydrazide C,H,(NO2).NH.N:CMe.CO2H. Yel Yellow (Fischer a. Ach, A. 253, 64). V. sol. hot alcohol.

p-Sulpho-phenyl-hydrazide SO₃H.C_cH₁.NH.N:CMe.CO₂H. Solid, insol. ether, v. sol. water and alcohol (Pfülf, A. 239, 217). -NaA' aq: nodules.

Phenyl-methyl-hydrazide C₁₀H₁₂N₂O₂ NPhMe.N:CMe.CO₂H. [78°]. Yellowish NPhMe.N:CMe.CO₂H. [78°]. needles (Fischer, B. 16, 2245; 17, 559). Converted by heating with HClAq into methyl-indole carboxylic acid and NH3. The phenyl-ethylhydrazide is converted in like manner into ethyl-indole carboxylic acid.

Di-phenyl-hydrazide
NPh₂.N.CMe.CO₂H. [145°]. White needles
(Fischer a. Hess, B. 17, 567). Sol. hot benzene and CHCl, forming deep-yellow solutions. Converted into phenyl-indole carboxylic acid by heating with HClAq.

o-Tolyl-hydraside C_sH₁MeN₂H:CMe.CO₂H. [156°] (J.); [159°] (R.) Formed by saponifying the product of the action of o-diazotoluene chloride on sodium methylacctoacetic ether (Japp, A. 217, 213), and from o-tolyl-hydrazine hydrochloride and pyruvic acid (Raschen, A. 239, 228). Small yellow plates (from benzene). Yields o-tolyl-hydrazido-propionio acid [148°] on reduction. At about 160° it forms the di-o-tolyl-di-hydrazine of dimethyl-di-ketone, a yellow crystalline powder

o-Tolyl-hydrazide C,H,N,H:CMe.CO,H. [162°]. Formed in the same way as the o-isomeride. Yellow plates (from benzene). At 165° it is converted into the di-p-tolyl-hydrazide of di-methyl-di-ketone [230°]. Gives an ethyl ether $C_{12}H_{16}N_2O_2$ [106°], crystallising from ligroin in yellowish plates.

BB

Methyl-p-tolyl-hydraside C,H, N,O, [83°]. Yellow prisms (Hegel, A. 232, 215). Ethyl-p-tolyl-hydraside C12H16N2O2.

Needles, v. sol. alcohol and ether (H.).

Ψ-Cumyl-hydrazide C_sH₂Me₃NH.N:CMe.CO₂H. r148°7. Vellow needles (Ruhemann, C. J. 57, 55).

p-Benzoylphenyl-hydrazide C.H.Bz.N.H:CMe.CO.H. [200°]. Lemon-coloured crystals (Ruhemann a. Blackman, C. J. 55, 616).

(a)-Naphthyl-hydrazide C₁₀H.,N₂H:CMe.CO₂H. [159°] (Fischer, A. 232, 236). Yields EtA [100°] (Schlieper, A. 239, 229).

(β) - Naphthyl-hydrazide [166°]. Yields
 EtA' [181°] (Schlieper, A. 236, 176).
 (B. 4)-Quinolyl-hydrazide

C.H.,N.NH.N:CMe.CO.H. [174°]. Formed from pyruvic acid and (B. 4)-hydrazido-quinoline acetate (Dufton, C. J. 59, 758). Light-yellow pp., insol. water, sol. acids and alkalis.

Oxim CH3.C(NOH).CO2H. a-Nitroso-propionic acid. Formed by the action of cold KOHAq on its ether, which is got by adding a dilute solution of KNO2 (10 pts.) to methylacetoacetic ether dissolved in water (3 pts.), KOH (2 pts.), and some alcohol, the yield being 16 p.c. of the methyl-acetoacetic ether used (V. Meyer a. Züblin, B. 11, 692; Gutknecht, B. 13, 1116). Got also from pyruvic acid and hydroxylamine (V. Meyer a. Janny, B. 15, 1527 : Schäfer, A. 264, 153; Hantzsch, B. 24, 50). Crystalline powder, sl. sol. ether, v. sol. water and alcohol. Decomposes suddenly at about 177°. Oxidised by potassium permanganate to ethyl-nitrolic acid CH₃.CH(NO)(NO₂). Yields acetonitrile on heating with hydroxylamine hydrochloride. Reduced by tin and HClAq to alanine. Salts .-KA' aq: pearly plates, sol. water.—BaA'2: soluble prisms.—Cu₂OA'₂ aq.—AgA': white insoluble powder. Ethyl ether EtA'. [94°]. (233° cor.). Formed as above, and also by the action of HNO2 on methyl-malonic ether and on propionyl-propionic ether (Bergreen, B. 20, 533). Needles or prisms, with weak acid properties.

References .- Bromo-, Chloro-, and Oxy-

PURTIFIC ACID.

PYRUVIC ALDEHYDE CH3.CO.CHO. Methyl-glyoxal. Got by the action of dilute acids upon CH₄.C(OH)(SO₃Na).CH(SO₃Na).NHSO₃Na, which is got from nitroso-acetone and NaHSO. (Pechmann, B. 20, 2543).

Mono-oxim v. NITROSO-ACETANE.

Di-oxim CH₂C(NOH).CH:NOH. Methylglyoxim. [153°]. Formed by the action of hydroxylamine on CH₂CO.CH.NOH or upon CH₂CO.CHCl₂ (V. Meyer a. Janny, B. 15, 1165; Treadwell, B. 15, 2787). Small prisms (from alcohol) or needles (by sublimation). Salt.— AgC₅H₂N₂O₂ pp.—Diacetyl derivative

[519]. C₂H₄(NOAc)₂. [51°]. (Schramm, B. 16, 2187). Prisms (from ligroin)

Phenyl-hydraside of the oxim CH,.C(N,HPh).CH:NOH. [184°]. Formed from nitroso-acetone and phenyl-hydrazine (Pechmann a. Wehsarg, B. 21, 2994; A. 262, 278). Prisms or needles (from alcohol). H.SO, forms a reddish-yellow solution, coloured deep blue by FeCl₃. Ac₂O yields CH₃.C(N₂HPh).ĈH:NOAc [163°], crystallising in colourless needles.

Phenyl-methyl-hydrazide of the oxim CH₃.C(N₂PhMe).CH:NOH. [118°]. Orange

yellow prisms (from alcohol).

Phenyl-hydrasids CH, CO.CH:N2HPh.

[150°]. Formed from sodium acetoacetic ether and diazobenzene chloride (Japp, A. 247, 198, 218; C. J. 53, 519). Plates (from benzene or MeOH). Yields CH₂-CO.CH:N₂AoPh [93°], orystallising from ligroin in needles. NaOEt and chloro-acetic ether yield, on saponification of the product, CH₃.CO.CH:N.NPh.CO.H [162°], which crystallises from hot water in needles, and is reduced by tin and HClAq to phenyl-amido-acetic acid [127°].

Di-phenyl-di-hydrazide CH₃.C(N₂HPh).CH:N₂HPh. [145°]. Formed by heating the phenyl-hydrazide of acetyl-carbinol with phenyl-hydrazine hydrochloride and NaOAc in alcohol at 100° (Laubmann, A. 243, 248). Formed also by warming pyruvic aldehyde or its mono-oxim, phenyl-hydrazide, or phenyl-hydrazide of the oxim with phenyl-hydrazine acetate (Pechmann, B. 20, 2543; 21, 2755; Japp, A. 247, 207). Yellow plates or needles (from dilute alcohol), sl. sol. alcohol. Conc. H, SO, forms an olive-green solution, changing through slaty-blue to violet. Yields a crystalline hydrochloride [197°]. Oxidised by K,Cr,O, and HOAC to CH N.NPh crystallising in needles [107°]. ČMe:N.NPh

whence boiling HClAq produces CH:N>NPh a colourless oil (150° at 60 mm.), oxidised by alkaline KMnO, to the acid C₀H₂N₃O₂ [192°].

Acetyl derivative of the di-phenyl-di-hydraside CH3.C(N2HPh).CH:N.NPhAc. [229°]. Formed from the acetyl derivative of the phenyl-hydrazide and phenyl-hydrazine (Japp, C. J. 53, 519). Yellowish needles.

Phenyl-methyl-hydrazide

CH. CO.CH:N.NPhMe. [64°]. Formed from the phenyl-hydrazide, NaOMe, MeOH, and MeI (Japp). Flat needles (from MeOH), v. e. sol. alcohol. Converted by phenyl-hydrazine into CH, C(N, HPh). CH: N. NPhMe [152°], crystallising in pale-yellow needles.

Phenyl-ethyl-hydrazide CH₃.CO.CH:N.NPhEt. [55°]. Prepared in like manner. Prisms (from ligroïn).

PYRUVYL ALCOHOL v. ACETYL CARBINOL.

QUARTENYLIC ACID v. ISOGROTONIC ACID. CHCl₃. Occurs in quassia-wood (Winckler, Rep. QUASSIN $C_{2:}H_{4:}O_{10}$ or $C_{2:}$

(10 pts.) with boiling water (45 pts.), evaporating (to 10 pts.) at a gentle heat, ppg. by tannin, mixing the pp. with lead carbonate, and extracting with boiling alcohol. The product is recrystallised from water and alcohol (yield 01 pt.) (Oliveri a. Denaro, G. 15, 6).

Properties.-Slender monoclinic needles, v. sol, alcohol and chloroform, sl. sol, ether. Sol, conc. HClAq and KOHAq, insol. Na₂CO₃Aq., Reduces Fehling's solution (Oliveri), or, according to Allen (An. 12, 107), has no reducing power. Not coloured by FeCl₂. Ppd. by tannin. Quassin appears to be the dimethyl ether of quassic acid, and probably contains two hydroxyls, two CO, Me, and two CO groups, and is perhaps a derivative of anthraquinone (Oliveri). Phenyl-hydrazine forms $C_{32}H_{40}O_8(N_2HPh)_2$ (?), a yellow amorphous powder, decomposing at about 230° without fusion (Oliveri, G. 18, 169).

Reactions.-1. Boiling dilute (4 p.c.) H2SO forms 'quasside' C₂₂H₂₂O₃, a white amorphous very bitter substance [194°], which reduces Fehling's solution, and is reconverted by boiling dilute alcohol into quassin. - 2. Ac O and NaOAc form, on boiling, the amorphous anhydride $C_{22}H_{40}O_8$ [150°-158°], sol. alcohol and ether.—3. Bromine forms $C_{22}H_{41}Br_3O_9$, a very bitter yellow powder [155°].—4. Fuming HClAq in a scaled tube at 100° forms MeCl and quassic acid.—5. PCl, gives C₃₂H₃₉Cl₃O₈, a yellow powder [120°] decomposed on fusion.—6. HIAq and P at 150°— 280° form durene (188°-195°) C₁₁H₁₆ (220°-240°) and anthracene (Oliveri, G. 17, 575).

Quassic acid $C_{30}H_{38}O_{10}$ or $C_{30}H_{40}O_{10}$. [245°]. S. 0043 at 23°. Formed, together with McCl (2 mols.), by heating quassin with HClAq. Monoclinic prisms (containing aq), sol. hot alcohol, sl. sol ether. Alkalis give a reddish-yellow colour. FeCl, gives a greenish-yellow colour. Reduces Fehling's solution and ammoniacal AgNO₂. Hydroxylamine forms C₁₀H₁₆(NOH)₂O₂ (?), crystallising in rectangular prisms [230°].—BaA"7aq: reddish-yellow crystals.—PbA"6aq: white amorphous pp.—Fe,A"₃: brownish-green pp.

QUEBRACHAMINE. [142°]. Occurs in white

quebracho bark (Hesse, A. 211, 269). Plates, v. sol. alcohol, benzene, CHCl, and ether. alcoholic solution is alkaline and tastes bitter. H₂SO₄ and K₂Cr₂O, give a dark-violet colour.

QUEBRACHINE $C_{21}H_{26}N_2O_3$. [216°]. [a]_D = 62·5 in a 2 p.c. alcoholic solution at 15°; = 18.6 in chloroform. Occurs in white quebracho bark (Hesse, B. 13, 2308; A. 211, 254). Colour-less needles, sol. alcohol, ether, benzene, and CHCl, v. sl. sol. cold water, NaOHAq, and Dextrorotatory. Its solutions are al-NH,Aq. kaline, bitter, and poisonous. Its solution in H,SO, is turned blue by PbO, or K,Cr,O,, and finally brown. FeCl, gives no colour. Salts.—B'HCl.—B'₂H₂PtCl₂ 5aq: crystals.-

B'2H,SO, 8aq: cubes or short prisms, v. sol. hot B₂H₂S₃O₄O₈H₂C₂O₄.—Tartrate B'₂H₆C₄O₆ faq.—Citrate B'₂C₄H₂O₇: nodular groups of needles.

Hypoquebrachine C₁₂H₂₈N₂O₂. [80°]. Strong base with bitter taste, v. sol. alcohol and ether,

forming yellow amorphous salts. Platino-chloride.—B'₂H₂PtOl₄4aq (Hesse, A. 211, 264). QUEBRACHITE C₆H₁₁MeO₆. [187°]. S.G. 2 1.54. (c. 210° in vacuo). [a]₀ = -80°. Occurs

in the seeds of Aspidosperma quebracho, from which it can be extracted with alcohol (Tanret,

C. R. 109, 908). Trimetric prisms with sweet taste, v. sol, water and alcohol, insol, ether. Does not ferment with yeast or reduce Fehling's solution. Reduces ammoniacal AgNOs. Not affected by dilute acids or alkalis at 100°. Ppd. by ammoniacal lead acetate, but not by lead subacetate. Heated with HI it gives off MeI and a little benzene. Ac.O and ZnCl₂ form an acetyl derivative [89°]. Gives on heating with HNO₂ the same reactions as inosite.

QUEBRACHO BARK. Quebracho blanco, or white quebracho bark, used as a febrifuge, contains about 8 p.c. of alkaloids, consisting of Aspr-DOSPERMINE, ASPIDOSPERMATINE, ASPIDOSAMINE, QUEBRACHINE, HYPOQUEBRACHINE, QUEBRACHAMINE,

and QUEBRACHOL (Hesse, A. 211, 251).
QUEBRACHO GUM. Occurs in quebracho colorado, the bark of Loxopterygium Lorentii (Jean, Bl. 28, 6; Arata, Anales de la Sociedad cientifica Argentina, July 1878; Feb. 1879; C. J. 34, 986). Brittle red concretions, with astringent taste, sol. boiling water and alcohol, insol. ether. Quebracho gum contains quebrachitannic acid, a pale-red amorphous mass, m. sol. hot water. giving a green colour with FeCl, turned dark red by NaOAc. Quebrachitannic acid ppts. Pb(OAc)2, gelatin, albumen, and alkaloids. yields pyrocatechin and a liquid (100°-120°) on distillation. Potash-fusion gives protocatechuic acid and phloroglucin; nitric acid yields oxalic and pieric acids.

QUEBRACHOL C₂₀H₃₄O. [125°]. [a]_D -29·3°. Occurs in white quebracho bark (Hesse, A. 211, 272; 228, 288). Plates, v. e. sol. alcohol and ether, insol. water and alkalis. When the solution in chloroform is shaken with H.SO. the chloroform is coloured red (cf. Cholesterin). .

A cetyl derivative $C_{20}H_{33}$. OAc. [115°]. QUERCETAGETIN $C_{27}H_{22}O_{13}$ 4aq. Yello Yellow crystals, extracted by alcohol from the blossoms of the common marigold, Tagetes patula (Latour

a. Magnier, Bl. [2] 28, 337). QUERCETIN $C_{21}H_{10}O_{11}$ 3aq (Liebermann a. Hamburger, B. 12, 1178) or C15H10O, (Herzig, M. 12, 172). (6)-Rhannetin (Herzig, M. 10, 561). [above 250°]. S. (alcohol) 5·5 at 78°; 4 in the cold (Stein, J. 1862, 499). Mol. w. (by Raoult's method) 258 (calc. 302). Formed, together with isodulcite, by the action of dilute H.SO, on quercitron, a yellow dye-stuff consisting of the shavings of the bark of Quercus tinctoria, growing in the United States (Rigaud, A. 90, 289). Rutin and robinin also yield quercetin when treated with dilute H.SO. (Zwenger a. Dronke, A. 123, 153; Suppl. 1, 261; Schunck, C. J. 53, 262; Hlasiwetz, A. 112, 96; J. pr. 94, 65). Occurs in Persian berries (Kane, A. Ch. [3] 8, 380; Bolley, C. J. 13, 327), in the ripe fruit, flowers, and leaves of the horse-chestnut (Rochleder, A. 112, 112), in the berries of the seabuckthorn (Hippophae rhamnoides), in appletree bark, in tea-leaves, and in catechu (Loewy. Fr. 12, 127).

Properties. — Lemon - yellow crystalline powder, sl. sol. water, v. sl. sol. ether. Gives off water of crystallisation at 130°. May be sublimed as yellow needles. Dissolves in alkalis, forming yellow solutions. Dyes fabrics mordanted with alumina yellow; with iron, grey or black. Its alcoholic solution is coloured dark green by FeCl, the colour becoming dark red on warming.

Pb(OAc)₂ gives a brick-red pp. Reduces AgNO₃ in the cold, and Fehling's solution on heating.

Reactions.—1. On fusion with potash it yields phloroglucin and quercetic acid, and by prolonged fusion, paradatiscetin C_{1.}H₁₀O₂, quercimeric and protocatechuic acid.—2. Boiling dilute alcoholic potash gives phloroglucin and protocatechuicacid (Herzig, M. 6, 863).—3. KClO₃ and HCl yield protocatechuic acid.—4. Sodium-amalgam forms phloroglucin, a compound C_{1.}H_{1.}O₃ crystallising in needles, sl. sol. water, and a compound C,H₂O₃, which forms granular crystals [130°], v. sol. water.—5. Bromine in HOAc forms C_{2.}H_{1.}Br_{2.}O_{1.} vystallising in lemon-yellow needles [237°] and yielding C_{2.}H₃Ac₃Br₃O₁₁. Excess of Brin HOAc forms C_{2.}H_{1.}Br_{2.}O_{1.}, vystallising from HOAc in needles [253°]. Licebermann obtained the compounds C_{2.}H_{1.}Br_{2.}O₁₁, C_{2.}H_{1.}Br_{2.}O₁₁, public the compounds C_{2.}H_{1.}Br_{2.}O₁₁, C_{2.}H_{1.}Pa_{2.}C_{2.}Br_{2.}O₁₁ [218°], C_{2.}H_{2.}Br_{2.}O₁₁, nad C_{2.}H₃c₃Br₃O₁₁ [228°], all crystallising in needles.—6. Phenyl cyanate at 160° forms C_{2.}H_{1.}Br_{3.}O_{1.} (Co.NHPh)₃, a white amorphous powyler [200°–205°] (Tesiner, B. 18, 2609).—7. Ammonia at 150° forms amorphous 'quercetamide' (Schützenberger a. Paraf, Z. 1862, 41).

 $\begin{array}{l} {\rm Salts.-C_{27}H_{20}K_{2}O_{13}\,(?).-C_{27}H_{20}Na_{2}O_{13}\,(?).-}\\ {\rm C_{27}H_{20}ZnO_{14}\,(II.\ a.\ F.).} \end{array}$

Acetyl derivative C., H., Ac., O., or C., H., Ac., O., (Herzig, M. 5, 72; 6, 890; 9, 557; 10, 561; 12, 174; cf. Liebermann, B. 12, 1178; A. 196, 319). [191°]. Formed by boiling quercetin or rhamnetin with Ac., O., and NaOAc. Needles (from alcohol). Liebermann obtained C., H., Ac., O., [198°], crystallising in needles.

Methyl ether C., H., O., (OMe). Rhamnetin.

Methyl ether C₁₃H₂O₄(OMe). Rhamnetin. Formed, together with isodulcite, by heating xanthorhamnin with dilute H₂SO₄ (Gellatly, N. E. P. J. 7, 256; Liebermann a. Hörmann, B. 11, 1618; Herzig, M. 6, 889; 9, 560; 12, 175. Lemon-yellow powder, nearly insol. water, alcohol, and ether, v. sol. hot phenol. Forms a yellow solution in KOHAq. Reduces ammoniacal AgNO₄ and hot Fehling's solution. Yields protocatechuic acid and phloroglucin on fusion with potash or on treatment with sodium-amalgam (Smorawski, B. 12, 1595). Converted by H1 into quercetin and MeI. Dyos iron mordants black and alumina yellow. Yields C₁₃H₃Ac₄O₄(OMe) [185°]. KOH and EtI give ethyl-rhamnetin [108°], whence Ac₅O and NaOAc form an acetyl-ethyl-rhamnetin [157°]. Rhamnetin yields also (tetra-?) propionyl [158°–162°] and (tetra-?) benzoyl [212°] derivatives, and an acetyl-dibromo-derivative [212°].

Methyl derivative C₂₁H₁₀Me₄O₁₁ or C₃₁H_Me₄O₄. [157°]. Formed from quereetin, KÖMe, and MeI (Herzig, M. 5, 83) and got also by heating xanthorhamnin with KMeSO, and MeOH at 120°, and from rhamnetin, KOH, and MeI (Liebermann a. Hörmann, A. 196, 317; Herzig, M. 6, 889; 9, 552). Golden needles, sl. sol. alcohol, converted by alcoholic potash at 140° into the di-methyl derivative of protocatechuic acid. Boiling AcO and NaOAc give C₂₁H₄Ac₂Me₄O₁ or C₁₅H₄AcMe₄O, crystallising in needles [167°].

Ethyl derivative C₃H₁₆Et₆O₁₁ or C₁H₄Et₆O₁ (122°]. Got by boiling quercetin with alcoholic potash and EtI (Herzig, M. 9, 587). Yellow needles, m. sol. alcohol. Yields

C₂H₃(OEt)₂CO₂H when heated with potash at 140°. Ac₂O and sodium acetate give the colourless acetyl derivative C₂₁H₈Ac₂Et₄O₁ or C₁₅H₁₅AcEt₄O, crystallising in needles [153°]. Mol. w. (by Raoult's method) c. 426 (Herzig, M. 12, 172).

A compound of quercetin and rhamnetin which sometimes occurs in Persian berries (Herzig, M. 10, 561) yields an acetyl derivative [171°], an acetyl-ethyl derivative [142°], and an ethyl derivative [102°].

[142°], and an ethyl derivative [102°].

Faradatiscetin C_{1.}H₁₀O₂. Formed from quercetin by potash-fusion (Hlasiwetz a. Pfaundler, J. pr. 94, 65). Yellowish needles (from dilute alcohol), nearly insol. water, m. sol. ether. Acid in reaction. FeCl₃ colours its alcoholic solution violet. Potash forms a yellow solution, turning green in air. Reduces AgNO₃ and Fehling's solution on heating. Potash-fusion yields phloroglucin but not protocatechuic acid. Boiled with water and BaCO₃ it yields BaA'₂ 2aq.—SrA'₂2aq.

Quercetic acid C₁₃H₁₀O₇ 3aq (?). Formed,

Quereetic acid C₁₃H₁₀O, 3aq (?). Formed, together with phloroglucin, by heating quereetin (1 pt.) with moist KOH (3 pts.) till a sample no longer gives a flocculent pp. with HCl and the residue quickly turns dark red at the edges (Hlasiwetz, A. 112, 96; 119, 213; J. pr. 94, 65). Slender silky efflorescent needles, si. sol. cold water, v. sol. alcohol and ether. Its aqueous solution turns yellow, and finally crimson, in air. H₂SO₄ forms a brown solution, whence water gives a red pp. forming a purple solution in NH₃Aq. FeCl₄ gives a blue-black colour. Reduces AgNO₃ Potash-fusion gives protocate-chuic acid. AcCl forms C₁₅H₈Ac₂O₇, crystallising from alcohol in prismatic needles.

from alcohol in prismatic necures.

Quercimeric acid C_AΠ_AO₃ aq (?). Formed from quercetin by potash-fusion. Colourless prisms, v. sol. water, alcohol, and other. Tastes bitter. Alkalis colour its solutions purple-red. FeCl₂ gives a dark-blue colour. Reduces AgNO₃ and Fehling's solution. Potash-fusion gives protocatechuic acid.

QUERCIN C₁H₀(OH)_g. [340°]. Occurs in oak bark, being obtained from the mother-liquors in the preparation of quereite (Gerber, A. 48, 348; Vincent a. Delachanal, C. R. 104, 1855; Friedel, 105, 95; Bl. [2] 48, 113). Efflorescent monoclinic prisms (containing xaq), sl. sol. water, insol. boiling alcohol. Inactive to light. Does not ferment with yeast, nor reduce Fehling's solution. Does not react with phenyl-hydrazine. Reduces ammoniacal AgNO₃ after addition of NaOH. Gives a gelatinous pp. with lead subacetate. After evaporation with IINO₃ it gives a rose-red colour with NH₃Aq and CaCl₂. Not coloured by boiling NaOHAq.

Acetyl derivative.—C_uH_u(OAc)_e. [301°].

QUERCITANNIC ACID C₁₇H₁₆O₉ or

C₁₈H₁₆O₁₉. S. ·6. S. (ether) ·035. Occurs in
oak bark, from which it is got by powdering,
sifting from bast fibres, extracting with dilute
alcohol, and shaking the filtrate with ether and
EtOAc. The acetic ether when evaporated deposits ellagic acid. The filtrate is evaporated
to dryness, and the residue washed with ether
and then extracted with Et₂O and EtOAc (Etti,
Sitz. W. [2] 81, 495; M. 1, 264; 4, 514; cf.
Stenhouse, A. 45, 16; Böttinger, A. 202, 270;
240, 331; 263, 112; Lowe, Fr. 20, 210). Occurs

also in tea (Rochleder, A. 63, 205). Reddishwhite powder. FeCl, colours the alcoholic solution dark blue. Pb(OAc)₂ ppts. the alcoholic solution. Quercitannic acid is not a glucoside (Etti). At 130° to 140° it forms an anhydride which gives C₃₄H₂₈BaO₁₇ (Etti). On evaporating with NaCl it is converted into a mixture of anhydrides which give with bromine-water an amorphous pp. $C_{10}H_{14}Br_{2}O_{10}$, m. sol. alcohol and EtOAc, v. e. sol. a mixture of these solvents, reacts with hydroxylamine, and is converted by Br into C19H10Br4O10, whence Ac2O forms C₁₉H,Ac,Br,G₁₀. QUERCITE

C₅H₁₂O₅. Penta-oxy-benzene Mol w. 164. [234°] Böttinger, hexahydride? B. 14, 1598). S.G. 131.585. S. 9 at 12°; 11 at 20°. $[a]_D = 24.17$. H.C. v. 710,100 (Berthelot a. Recoura, A. Ch. [6] 13, 341). H.F. 268,200. R_{∞} 58.95 in a 7.7 p.c. aqueous solution (Kanonnikoff). Occurs in acorns (Braconnot, A. Ch. [3] 27, 392; Dessaignes, A. 81, 103, 251; Prunier, A. Ch. [5] 15, 5; U. R. 84, 1318; 85, 808; 86, 338, 1460; Hofmann, A. 190, 282).

Preparation. - Acorns are extracted with cold water, the extract concentrated at 40°, ppd. by lead subacetate, filtered, mixed with yeast to remove sugar, and, after fermentation, freed from lead by H₂S, and evaporated to crystallisa-

Properties. — Monoclinic prisms, a:b:c = *800:1: 766, $\beta = 68$ °57', insol. other, benzene, and chloroform, v. sl. sol. hot alcohol. Does not undergo alcoholic fermentation. Dextrorotatory. Does not render borax solution acid.

Reactions .- 1. At 100° it slowly loses water, forming $C_{21}\Pi_{10}O_{19}(?)$. At 240° in vacuo it gives $C_{12}H_{22}O_{9}$ [230°], v. sl. sol. water. Rapidly heated to 290° it swells up and gives off quinhydrone and hydroquinone.—2. Potash-fusion gives quinone, hydroquinone, CO₂, formic acid, and oxalic acid.—3. H₂SO₄ and MnO₂ give quinone. 4. Conc. HClAq forms, at 100°, C₂H,Cl(OH)₄ [200°], sol. ether, and viscid C₂H₂ClO₃, which is converted by baryta-water into amorphous quereitan $C_cH_{10}O_1$, sol. water and alcohol, insol. ether. HClAq at 120° – 140° gives $C_cH_1Cl_4(OII)_2$ [155°], converted by further treatment with HCI into C.H.Cl. [102]. - 5. Distillation with HIAq forms benzene, phenol, iodo-phenol, quinone, hydroquinone, and hexane. - 6. Nitric acid forms mucic and tri-oxy-glutaric acids (Kiliani a. Scheibler, B. 22, 517).-7. Phenyl cyanate at 165° forms C₈H,(O.CO.NHPh), [120°-140°], a white amorphous powder (Tesmer, B. 18, 2606).

8. Benzoic acid at 200° forms solid 'benzoquercite ' CaH10Bz2O3 (?) insol. water, sol. alcohol and ether. Stearic acid forms a similar body, while tartaric acid gives 'quercitartaric acid C₂₂H₃₂O₂₇ (Berthelot, C. R. 44, 452; A. Ch. [3] 54, 82).

Salts. - (C.H.,O.) Ba 3aq: amorphous, sol.

water and alcohol.—(C₆H₁,O₃)₂CaSO, 2aq.

Acetyl derivatives. The compounds

C₆H₁,AcO₃, C₆H₁,AcO₃, C₈H₈AcO₃, C₈H₈AcO₅,
and C₆H₄AcO₃ have been prepared.

Butyryl derivatives. Heating with butyric acid gives rise to C_sH₁₁(C_tH₂O)O_s, C₆H₉(C₄H₇O)₂O₃, and C₆H₇(C₄H₇O)₅O₅, all being amorphous with bitter taste.

Pentanitrate C₄H₁(NO₃)₃. Formed from queroite (1 pt.), H₂SO₄ (10 pts.) and HNO₃

(4 pts.) (Hofmann, A. 190, 288). Resin, insol. water, sol. alcohol and ether. Explodes when heated. Zinc-dust and alcoholic soda give off

heated. Zinc-auss and action the N as NH₃.

QUERCITRIN C₃₆H₃₈O₂₆ or, more probably,
C₃₁H₂₀O₁₂ (Herzig, M. 14, 53). [168°]. S. 04 in
the cold; 7 at 100°. S. (alcohol) 4 in the cold
29 at 78° (Stein). S. (ether) 8 (Schunck, C. J 53, 201). Geenam question and the state of the control of the cont J. pr. 85, 351; Hlasiwetz, A. 112, 109). Occurs also in fully-developed horse-chestnut leaves (Rochleder a. Kawalier, Sitz. W. 55 [2] 46), in leaves of the ash (Gintl, Z. [2] 4, 732), and in leaves of Andromeda japonica (Eykman, R. T. C. 2, 200).

Preparation .- Quercitron bark is exhausted with alcohol, and the evaporated extract dissolved in water and shaken with ether. The ethereal solution is evaporated, the residue dissolved in alcohol, and the quercitrin ppd. by water and crystallised from boiling water (Löwe,

Fr. 14, 233; cf. Herzig, M. 6, 877).

Properties.—Yellow needles or plates (containing 3aq). Neutral and tasteless. Nearly insol. cold water, sol. alkalis and HOAc. FeCl. colours its solution dark green. FeSO, gives no colour. Ppd. by I'b(OAc). Reduces aqueous AgNO₃ in the cold, and Fehling's solution after long boiling. Boiling dilute acids split it up into quercetin (q.v.) and isodulcite (Liebermann a. Hamburger, B. 12, 1178). Bromine forms $C_{30}\Pi_{41}Br_{1}O_{20}$, which is crystalline and is decomposed by acids into isodulcite and tetra-bromoquercetin.

Salt.-C36H36K2O20: yellow pp. Violaquerotrin C_EH₄₀O₂₁. Occurs in Viola tricolor (Mandelin, J. 1883, 1369). Yellow needles (from water). Split up by dilute acids

into glucose and quercetin.

QUILLAJIC ACID C₁₁₁II₂₀O₁₀. Extracted by water from the bark of Quillaja Saponaria (Kobert, C. C. 1888, 972). White flakes, sol. water and alcohol, insol. ether. Coloured dark red by H2SO4. Boiling dilute acids split it up into sapoginin and an unfermentable glucose. The Na salt violently attacks the mucous membrane, and is very poisonous when injected into the blood.

QUINACETOPHENONE is DI-OXY-ACETO-PHENONE.

QUINALDINE v. METHYL-QUINOLINE. QUINALDINIC ACID v. QUINOLINE CARB-

OXYLIC ACID. QUINAMINE v. vol. ii. p. 179.

QUINAMICINE v. vol. ii. p. 180.

QUINAMIDINE v. CINCHONA BASES. QUINANISOLE v. Methyl derivative of Oxy-

QUINOLINE. QUINAZOLE v. METHYL-INDAZINE.

QUINAZOLINE. This name is given to the ring C.H. CH:N v. Oxy-QUINAZOLINE.

QUINAZOLINE DIHYDRIDE C,H,N, i.e. $C_sH_s < \stackrel{CH_s,NH}{N=CH}$. [127°]. Formed by reducing o-nitro-benzyl-formamide by Zn and HClAq (Gabriel a. Jansen, B. 23, 2814; 24, 3097). Yellowish crystals, sol. warm water, forming an alkaline solution.—B'HCl.—B'C₈H₈N₂O₇. [215°]. Small crystals, sl. sol. water.—B'₂H₂PtCl₈.

QUINENE v. vol. ii. p. 181. QUINETHONIC ACID C₁₄H₁₈O₈ i.e. C.H.(OEi).C.H.O., [146°]. Occurs in urine after a dose of C.H., OEt (Kossel, H. 4, 296; 7, 292; Lehmann, H. 13, 181). Crystalline. Lesvorotatory. Does not reduce Fehling's solution. Converted by dilute H2SO4 into crystalline The double salt Pho.So. BaA'aq (dried at 110°) and with cresol and indoxyl the corresponding C,H,O.SO,BaA'aq and C,H,NSO,BaA', all three

QUINHYDRONE C₁₂H₁₀O₄. Formed by mixing aqueous solutions of quinone and hydroquinone; by oxidising hydroquinone; and by reducing quinone (Wöhler, A. 51, 153; Liebermann, B. 10, 1614, 2000; Hesse, A. 200, 248; Nietzki, A. 215, 130; Wichelhaus, B. 5, 840; 12, 1500; Stenhouse a. Groves, B. 13, 1305). Brownishred prisms, with green metallic lustre. May be sublimed. Sl. sol. cold water, v. sol. alcohol and ether, forming yellow solutions. Decomposed by boiling water, giving off quinone and leaving a solution of hydroquinone. Its ammoniacal

QUINIC ACID C,H₁₂O₆ i.e. C₆H₁(OH), CO₂H.

Mol. w. 192. [162° cor.]. S.G. *5 1-637 (Henry a. Plisson, B. J. 10, 186). S. 40 at 9°. $[a]_D = -44^\circ$ at 20° in a 20 p.c. solution (Thomsen, J. pr. [2] 35, 156). H.C. 833,700. H.F. 238,300 (Berthelot a. Recoura, C. R. 105, 144; Bl. [2] 48, 703; A. Ch. [6] 13, 342). R_{∞} 66.52 in an 18 p.c. aqueous solution (Kanonnikoff, J. pr. [2] 31, 348). Occurs as calcium salt in cinchona bark (Hoffmann, Crell's Ann. 2, 314; Vauquelin, A. Ch. 59, 162; Pelletier a. Caventou, A. Ch. [2] 15, 340; Liebig, P. 21, 1; 29, 70; Baup, A. Ch. [2] 51, 5; A. 6, 7; Woskrosensky, A. 27, 200; Hesse, A. 110, 194; 112, 52; 114, 292; 176, 124; Clemm a. Will, A. 110, 345). Occurs also in the bilberry plant (Vaccinium Myrtillus) (Zwenger, A. 115, 108; 129, 203; Suppl. 1, 77), in the leaves and beans of the coffee-plant (Z.), and in hay

(O. Loew, J. pr. [2] 19, 310; 20, 476).

Preparation.—Cinchona bank is extracted with dilute H₂SO₄, the extract ppd. by milk of lime, filtered, and evaporated. The residue is boiled with alcohol and the calcium quinate left undissolved is crystallised from water and de-

composed by oxalic acid.

Properties.-Monoclinic prisms. V. e. sol. water, m. sol. alcohol, nearly insol. ether.

Levorotatory.

Reactions .- 1. Heated to 200°-225° it gives off aq, forming quinide C,H₁₀O₅, a crystalline anhydride, v. sol. water, sl. sol. dilute alcohol. Quinide is acid in reaction, and is reconverted by bases into quinic acid. On dry distillation quinic acid gives hydroquinone, phenol, benzoic acid, and pyrocatechin.—2. Ac₂O at 170° forms tri-acetyl-quinide C₆H,(OAc)₃<0

and tetra-acetyl-quinic acid (Erwig a. Königs, B. 22, 1458; cf. Hesse, A. 200, 233). By further heating with Ac.O at 240°-250° monoclinic crystals of iso-tri-acetyl-quinide [189°] are obtained.—8. Bromine added to an aqueous

solution forms protocatechuic acid (Hesse).--4. Hot H₂SO₄ forms CO and hydroquinone disulphonic acid.—5. Hydroquinone is formed by boiling the aqueous solution with PbO₂. Distillation with MnO₂ and dilute H₂SO₄ yields quinone (detection of quinic acid in bark: Stenhouse, A. 59, 100).—6. HNO, gives oxalic acid. 7. KClO, and HCl give chlorinated quinones and chlorinated acetones (Städeler, A. 69, 300; 111, 293).—8. Conc. HIAq at 120° reduces it to benzoic acid (Lautemann, A. 125, 9).—9. Conc. HClAq at 150° gives p-oxy-benzoic acid and hydroquinone (Hesse, A. 200, 232). Dilute (3 p.c.) HClAq at 100°-120° forms phenol, hydroquinone, and p-oxy-benzoic acid (Chadounski, C. C. 1888, 1029). — 10. Fuming HBrAq at 130° gives protocatechuic and benzoic acids (Fittig, A. 193, 197).-11. PCls forms m-chloro-benzoyl chloride (Graebe, A. 138, 197). 12. Gives protocatechuic acid on fusion with KOH or NaOH .- 13. Boiling with iodine and KOHAq yields iodoform.—14. Calcium quinate fermented by schizomycetes in presence of air yields protocatechuic acid, in absence of air it gives propionic, acetic, and formic acids (Löw, B. 14, 450).

Salts .- NaA' 2aq .- NaA' 5aq. BaA', 6aq: dodecahedra, very soluble in water.-CaA' 10aq. S. 17 at 16°. Plates, insol. alcohol. -CaA'Ac aq (Gundelach, B. 9, 852).—SrA'₂10aq.
-SrA'₂15aq.—MgA'₂6aq.—CdA'₂. S. '4 in the cold.—ZnA'₂.—CoA'₂5aq.—NiA'₂5aq: crystals.
CuA'₂5aq: blue needles.—CuC,II₁₀O₄2aq. S. '09 at 18°.—PbA'₂2aq: needles, sol. alcohol, v. e. sol. water.—Pb₂C₇H₈O₆. Amorphous, insol. water.—MnA'₂. S. 5 in the cold.—FeC₁₄H₂₁O₁₅. -AgA': mammellated groups of crystals.

Ethyl ether EtA'. Viscid mass, with

bitter taste, v. sol. water and alcohol. Converted by boiling Ac₂O into C₈H₇(OAc), CO₂Et crystallising from water in plates [135°], sl. sol. boiling water.

Tetra-acetyl derivative

C₆H₂(OAc)₁.CO₂H. [130°-136°]. Formed by heating quinic acid with Ac₂O and ZnCl₂ (Erwig a. Koenigs, B. 22, 1461). Crystalline crusts, sl. sol. cold water, insol. ligroin.—AgA': needles.

Anilide C₁₃H₁₇NO₃. [174°]. Formed by heating quinic acid with aniline at 180°. Small silky needles (containing aq), v. sol. water and alcohol, sl. sol. ether.

QUINICINE v. CINCHONA BASES. QUINIDE v. QUINIC ACID.

QUINIDINE v. vol. ii. p. 180. QUINIENE v. vol. ii. p. 181.

QUININE C₂₉H_{2l}N₂O₂ [173° cor.] (Lenz, Fr. 27, 559; Hesse, A. 258, 133). The trihydrate melts at 57° (H.). S. 05 at 15° (Regnauld, J. Pharm. Chim. [4] 21, 8). S. (of the trihydrate) 06 at 15° (Hesse, B. 10, 2152); 06 at 100 (15 to 100); 15 to 100 (15 to 100); 16 to 100 (15 to 100); 16 to 100 (15 to 100); 17 to 100 (15 to 100); 18 to 100); 18 to 100 (15 to 100); 18 to 100); 18 to 100 (15 to 100); 18 to 100); 18 to 100 (15 to 1 drate) '06 at 15' (Hesse, B. 10, 2152); '06 at 20°, '11 at 100° (Sestini, Fr. 6, 359). S. (of the anhydrous base) '051 at 15' (H.); '07 at 20°, '13 at 100° (S.). S. (ether) 100 at 10° (Hesse, A. 135, 327); 4.4 at 18° (van der Burg, J. 1865, 438). A conc. ethereal solution often gelatinises, The quinine thus separated being less sol. ether (S. about 5 at 15°). S. (chloroform) 57.5 (Pettenkofer, J. 1858, 363). S. (benzene) -5 at 15° ; 3.8 at 80° (Oudemans, J. 1874, 867). S. (xylene) -11 at 15° ; -645 at 138° (Swaving, R. T. C. 4, 186). $[a]_{\rm B} = -166^{\circ}$ at 18° ; -163°

at 25° in alcoholic solution (Hesse, A. 166, 217) -145.2 + .657p in a solution of p grammes in 100 c.c. of 97p.c. alcohol at 15° (Hesse, A. 176, 206; 182, 131). [α]_D = -158.7 + 1.911p in an ethereal solution containing from 1.5 to 6 p.c. base. In solutions containing not note than 1.6 p.c. quinine, Oudmans, jun. (Ar. N. 10, 193), found $[a]_b = -167.5^\circ$ (in alcohol); -136° in benzene; -127° in toluene; -117° in chloroform. Dispersive power: Grimbert, J. Ph. [5] 16, 295,

Occurrence.—In cinchona bark, v. vol. ii. p. 175. According to Grimaux (Bl. [3] 7, 304), cupreine heated with NaOMe, MeOH, and MeCl or MeNO, yields 10 to 15 p.c. of quinine, while MeI gives chiefly quinine di-methylo-di-iodide.

Preparation .- The bark is extracted with dilute H2SO,, and the solution ppd. by NaOHAq. The pp. is dissolved in ether, the ether shaken with dilute H₂SO₄, and the boiling solution neutralised by ammonia. Quinine sulphate separates on cooling. The sulphate is decomposed by ammonia.

References. — Vide references in articles Cinchona Bark and Cinchonidine, and also Pasteur, C. R. 36, 26; 37, 110, 162; Schützenrasteur, U. M. 30, 26; 37, 110, 162; Schützenberger, A. 108, 347, 350; Robiquet, A. Ch. [2] 17, 316; Stratingh, R. P. 15, 139; Pelletier, J. Ph. 11, 249; Duflos, B. J. 27, 1, 110; Strecker, A. 91, 155; Thiboumery, J. Ph. [3] 16, 369; Alluard, J. Ph. [3] 46, 192; Körner, Z. [2] 1, 150; Bouchardat, A. Ch. [3] 9, 213; De Vrij, N. J. P. 14, 268; Laudrin, C. R. 108, 750.

Properties.—Phd. by ammonic from solvers.

Properties .- Ppd. by ammonia from solutions of its salts in an amorphous anhydrous form, which quickly changes, especially in presence of free ammonia, into the crystalline hydrate (containing 3aq), consisting of minute four-sided prisms terminated by pyramids. The hydrate gives off its water of crystallisation over H₂SO₂. Quinine is v. e. sol. ether and alcohol, v. sol. CS₂, m. sol. benzene, v. sl. sol. ligroïn, sol. volatile and fixed oils. It is alkaline in reaction. Its solutions are levorotatory. A 5 p.c. solution of the sulphate gives $\alpha = -22^{\circ}$ in a depth of 200 mm. (Rozsnyay, Fr. 23, 589). Its solutions in dilute H2SO, HNO3, H3PO4, and HOAc exhibit blue fluorescence, destroyed by HCl, HBr, HI, or H₄FeCy₈. Fluorescence of the sulphate is prevented by a large excess of sulphate of cupreïne (Grimaux a. Arnaud, Bl. [3] 7, 304). Chlorine-water and ammonia give a green pp. dissolving in excess of ammonia to an emerald green liquid. On addition of an acid the colour changes through blue (when neutral) to red, the green colour returning on adding ammonia (Brandes, Ar. Ph. 13, 65; André, J. Ph. 22, 132). Excess of chlorine-water and of ammonia should be avoided. Chlorine does not render a solution of quinine sulphate turbid (Lepage, J. Ph. 26, 140). Bromine-water and ammonia give the green colour even in exceedingly dilute solutions (Flückiger, Fr. 11, 318). The green colour may be also got by mixing 01 g. of the salt to be tested with an equal bulk of KClO₃ and a drop of conc. H.SO, followed by excess of ammonia (Mylius, C. C. 1886, 602). Chlorine-water followed by K,FeOy, gives a red colour in a alcohol, insol. ether and NaOHAq. Alcoholic solution of quinine sulphate (Vogel, A. 73, 221; NH, converts this salt into C₂₀H₂₁N,O₂HI? which 86, 122). Quinine gives the usual alkaloidal is white, v. sol. alcohol, al. sol. ether [155°-

reactions. It is coloured green by potash-fusion (Lenz, Fr. 25, 81). Potassium sulphocyanide gives a white pp., sol. excess (Schrage, Ar. Ph. [3] 13, 25). Boiled with dilute H₂SO₄ and PbO, quinine forms quinetin, a red substance (Marchand). Dilute HNO, gives no colour. Sunlight acting on an aqueous solution, even in an atmosphere of H, ppts. brown flocculent quiniretin, insol. water, alcohol, and ether (Flückiger, Ph. [3] 8, 885). ICl gives a light-brown crystal-line pp., sl. sol. HClAq. Quinine is antiseptic, hindering putrefaction and the alcoholic, lactic, and butyric fermentation. Quinine is a febri-

fuge. Its salts taste bitter. Reactions .- 1. The sulphate is oxidised by

KMnO, to pyridine tricarboxylic acid, oxalic acid, and NH, (Hoogewerff a. van Dorp, B. 12, 158). At 0° the first product is chitenine (n.H₂₂N₂O₄, which crystallises in colourless prisms [240°–286°], insol. ether and alcohol, prisms [240°-286°], insol. etner and alcoho, sol. dilute acids and alkalis (Skraup, B. 12, 1104; M. 10, 39). Quinine (5 g.) is apparently oxidised by KMnO₄ (50 g.) to pyridine dicarboxylic acid (Ramsay a. Dobbie, C. J. 33, 102). Boiling nitric acid also forms pyridine dicarboxylic acid. oxylio (cinchomeronic) acid. Aqueous CrO, oxidises quinine to quininic or methoxy-quinoline carboxylic acid.—2. A mixture of HNO, and H2SO, reacts, and on diluting an amorphous pp., apparently $C_{20}H_{22}(NO_2)_2N_2O_2H_2O$ is got (Rennie, C. J. 39, 469).—3. PCl₃ converts is got (hennie, C. J. 31, 403).—5. FO, converts it into colourless quinine-chloride $C_{20}H_{22}N$,OCI [151°] which by boiling with alcoholic KOH gives chinen $C_{20}H_{22}N_2O$ (Comstock a. Königs, B. 17, 1988).—4. Reduced by zinc and dilute H_2SO_4 to hydroquinine $C_{20}H_{20}N_2O_{20}$ an amorphous bitter resin (containing aq), sol. alcohol and ether, giving a green colour with chlorine-water and aminonia (Schützenberger, A. 108, 347).-5. Heated with water at 250° it yields quinoline (Reynoso, C. R. 24, 795). The same body is formed by heating with conc. KOHAq at 190° (Gerhardt a. Wertheim, J. 1840, 370).—6. Fuming H2SO4 forms a sulphonic acid. Conc. Husto, dissolves quinine, forming isocinchonine. Dilute H₂SO₄ at 125° converts quinine into quinicine.—7. *Iodic acid* gives off much gas on warming (Brett, J. Ph. [3] 27, 116).—8. Conc. HClAq at 150° forms McCl and apoquinine. (Hesse, A. 205, 317). Concentrated HClAq at -17° slowly forms hydrochloroquinine C₁₀H₂ClN₂O₁[87°], while hydrogen bromidegives C₂₉H₂BrN₂O₂, which forms B'H₂Br₂ (Comstock a. Königs, B. 20, 2510).—9. Heated for a long time with 12 pts. of HIAq. S.G. 1-96 for 3 hours at 100° it gives methyl iodide and a yellow salt C₁₉H_{2,N}N₂O₂3HI [238°] sol. alkalis. Alcoholic NH₂Aq converts it into C₁₉H_{2,N}N₂O₂2HI mixed with a little C₁₉H_{2,N}N₂O₂HI, which yields an oxalate [187°] (C₁₉H_{2,N}N₂O₂HI)H₂C₂O₄ mixed with (C₁₉H_{2,N}N₂O₂H₂H₂D₁H₂CO₄ (Schubert a. Skraup, M. 12, 684). HBrAq acting on quinine at 100° forms C₁₉H₂BrN₂O₃HBr aq, crystallising in needles, from which sodium carbonate sets free C₁₉H₂N₂N₂O₂, a powder [210] (Julius, M. 6, 751). at -17° slowly forms hydrochloroquinine needies, from which solution carbonate sets free C₁₉H₂₂BrN₂O₂, a powder [210] [Julius, M. 6, 751). 10. Quinine dried at 120°, heated with HIAq (S.G. 1.7) at 100°, forms C₂₉H₂₂N₂O₂3HI [280°], a yellow crystalline mass, v. sl. sol. water, sl. sol.

160°]. Its solution in dilute H₂SO, shows blue fluorescence, and gives a brownish-yellow pp. with chlorine-water and ammonia. It gives rise to the salts ((C₂₀H₂₁N₂O₂),H₃I₃)₂8H₂C₂O₄? and C₂₀H₂₁N₂O₂H₂HNO₃? [217°] (Schubert a. Skraup, M. 12, 678; cf. Lippmann a. Fleissner, M. 12, 329).—11. Bromine added to a solution of quinine in dilute H2SO4 ppts. B'Br2 2aq, B'2Br6, and B'Br, as bitter yellow curdy pps., melting at 160°-180° (Colson, C. R. 108, 678).

Estimation.—V. Cinchona Bark. V. also Lenz, Fr. 27, 549-631. Quinine may be ppd. as chromate (De Vrij, C. C. 1889, 708; Ar. Ph. [3] 24, 1073; Vulpius, Ar. Ph. [3] 24, 1022; Schlikum, Ar. Ph. [3] 25, 128; Hesse, Ph. [3] 17. 585). A solution of quinine sulphate requires more ammonia to redissolve the pp. first formed than solutions of the sulphates of the alkaloids usually present with it (Kerner a. Weller, Ar. Ph. [3] 25, 712,749; Fr. 1, 159; 27, 115; cf. Schäfer, Ar. Ph. [3] 25, 1033; Ruddiman, C. N. 58, 202, 216, 226; Jungfleisch, J. Ph. [5] 15, 5). Use may also be made of the sparing Bolubility of quinine oxalate in presence of K₂C₂O₄ (Schäfer, Ar. Ph. [3] 25, 64, 1041).

Constitution.—Chitenine C₁₀H_{2,}N₂O₄ may be

got by oxidation of both quinine and cinchonine. On further oxidation chitenine yields quinic, pyridine tricarboxylic, and cincholeuponic acids. From this it may be surmised that one half of the quinine molecule has the same composition as one half of the cinchonine molecule (Skraup, M. 10, 39, 220). Quinine, quinidine, and quinicine are probably stereo-isomeric, since they give the same products of oxidation; they are derivatives of (B. 2)-methoxy-quinoline while cinchonine is a derivative of quinoline. Cincholeuponic acid C_sH₁₃NO₄ [225°] yields C_sH₁₃NO₄ĤCl [194°] and C_sH₁₂AcNO₄, and is converted by nitrous acid into the dibasic nitroso derivative C₂H₁₂(NO)NO. Oxidation of quinine also yields a base, cincholeupone C₂H₁NO₂ oxidised by CrO₂ to cincholeuponic acid and other products. Cincholeupone when heated with zinc-dust yields (B)-ethyl-pyridine. By nitrous acid cincholeupone is converted into C_bH_{1s}(NO)NO₂, which is an acid. Ac₂O forms acid C_bH_{1s}AoNO₂. Oxy-quinoline (cynurine) is also a product of oxidation of quinine. From these experiments Skraup concludes that quinine and cinchonine contain a quinoline nucleus united to an ethyl-pyridine nucleus; quinine being methoxy-cinchonine. Cupreïne heated with NaOMe (1 mol.), McI (6 mols!), and McOH forms quinine di-methylo-di-iodide (Hesse, A. 266, 244; cf. Grimaux a. Arnaud, C. R. 112, 774; A. 267, 379). The chief product is, however, cupreïne mono-methylo-iodide.
only 1 mol. MeI is used, no quinine is got.

Salts.—C₂₀H₂₂AgN₂O₂ Gelatinous pp. got by adding AgNO₃ to a solution of quinine in alcoholic NH₃ (Skraup, M. 2, 613).—B'HCl 2aq: groups of white needles (Hesse, A. 176, 210; 267, 142). Melts (when anhydrous) at 160° without undergoing any change. S. 2.5 at 10°. V. e. sol. alcohol and ether. $[a]_0 = -134^{\circ}$ in a 2 p.c. solution at 17° (Oudemans). Its solution is not ppd. by silver nitrate (1 mol.) until added in excess (Vulpius, Ar. Ph. [3] 20, 361) .-

or gelatinous mass. S. 100 in the cold. Melts at 15° (A. Clermont, J. Ph. [5] 15, 15). B'H,PtCl, aq: yellowish flocculent pp., soon becoming orange and crystalline (Gerhardt, B. J. coming orange and crystalline (Gernardt, B. J. 23, 354). S. 07 in the cold; 8 at 100° (Duflos). —B'_H_PtCl_3aq: orange amorphous pp. (Hesse, A. 207, 308).—B'H_HgCl_1. Ppd. by mixing alcoholic solutions of quinine, HCl, and HgCl_2 (Hinterberger, A. 77, 201).—B'_H_ZnCl_2aq: prisms (from alcohol) (Gräfinghoff, Bl. [2] 4, 391).

B' H ZnCl_2ac_arrestalline — B'H Br_3ac_arrestalline — - B'2H, ZnCl, 3aq: crystalline. - B'H, Br, 3aq: crystals, v. e. sol. water.—B'HI: lemon-yellow prisms (Herapath), or heavy white powder. Sl. sol. water, v. e. sol. alcohol (Winckler, Jahrb. pr. Pharm. 20, 321). Melts at 150°-155°, but softens at about 100° and then blackens (Lippmann a. Fleissner, M. 13, 436).—B'HIEt20 (from ether). Crystals.—B'H_IL_5aq (Regnault). Crystals. V. Reaction 9, supra.—B'H_IL,: [230°]. Converted by NH_Aq into B'HI.—B'_2H_SO, 8aq (Hesse, A. 119, 361; 225, 97; Carles, BL. [3] 7, 108; cf. Cownley, Ph. [3] 7, 189). Commercial specimens are somewhat effloresced. Monoclinic efflorescent prisms. Loses 6aq over H,SO. S. chloreform and fatty oils. [\alpha]_D = 163° in a 2 p.c. solution in 80 p.c. alcohol.—B'H_SO, 7aq. [100°]. Rectangular prisms (from hot solutions) or small needles. S. 9 at 13°; 12.5 at 22°. or small nections. B. 3 at 15, 125 at 25. Loses 6aq over H_2SO_4 . $[a]_b = -164.9 + 31p$ in a solution of p g. in 100 c.c. water, where p is between 1 and 6 (Hesse, A. 176, 215; 182, 134).—B'(H₂SO₄)₂ 7aq: prisms, v. e. sol. water, m. sol. alcohol. Its hot alcoholic solution deposits gelatinous B'(H_2SO_4)₂5aq. [α]_D = -170 + 94p.— B'₂ $H_2Cl_2H_2SO_4$ 3aq. Mass of small needles, \mathbf{v}_{\bullet} sol. water. S. (of anhydrous salt) 86. [120°] (hydrated); [165°-170°] (anhydrous) (Grimaux, Bl. [3] 7, 819).—B'₂H₂Br₂H₂SO₄ 3aq. S. 26 at 21°.-B'2H,L,H,SO, 2aq: yellow crystals, form-21°.—B₂H₂H₂B₂O₂ 2aq: yeilow crystalis, norming a colourless solution. Crystallises also with 4aq.—B'₂H₂Cl₂H₃PO₁9aq: small needles, solwater. - B'₂H₂B₇H₁PO₁7aq. - B'₂H₃I₄H₂PO₆6aq. - B'₂H₃S₀O₂2aq. S. 3 (Wetherill, A. 66, 150; How, N. Ed. P. J. [2] 1, 47).—B'HNO₂ aq: prisms (Strecker, A. 91, 159).—B'AgNO₃ aq: crystalline pp. Chlorate.—B'HClO, 2aq (Tichborne, Z. 1866, 665; cf. Serullas, A. Ch. [2] 45, 279).—B'(HClO₄), 7aq: trimetric octahedra.—B'(HClO₄) 2aq. [210°] (Boedeker, A. 71, 61).—B'(HO₄) 3aq: needles (Langlois, A. Ch. [3] 31, 274).—B'₄(HCl)₅(HI)₄II; small brown crystals.—B'₄(HCl)₅(HI)₄II; blackish-groen flat needles Herapathite. Formed by adding an alcoholic solution of iodine to a solution of quinine sulphate in HOAc (Herapath, P. M. [4] 3, 161; 4, 186; 6, 171, 346; 7, 352; 9, 366; 14, 224; C. J. 11, 130; Haidinger a. Stokes, Sitz. W. 10, 106; Jörgensen, J. pr. [2] 14, 230). Large colourless plates with metallic green lustre. Polarises light, so that two plates at right angles are opaque. S. (90 p.c. alcohol) 125 at 16°. Decomposed by cold water. Dried over H.SO, they become B',(H,SO), I, 3aq (Hauer, Z. [2] 1, 481).

—B',(H,SO),(HI),I, 2aq. Crystals, resembling B'HOl 1 saq. Large monoclinic octahedra, deposited at 0°.—B'2HCl. Groups of white needles, herapathite, decomposed by hot alcohol into

iodine and herapathite. -B's(H2SO4)s(HI)4I144aq: | iodine and herapathite.—B'₁(H,SO₁)₆(H1),I₁, 4aq: brownish needles.—B'₂H₂SO₄(H1),I₂; red needles.—B'₂H₂SO₄(H1)₂I₄: brown rectangular plates with olive-green reflex.—B'₂H₂SO₄(H1)₂I₈: black crystals with green reflex.—B'₂(H,SO₁)₂(H1)₂I₈.—B'₃(H,SO₁)₂(H1)₂I₄.—B'₄(H,SO₁)₂(H1)₂I₅.—B'₄(H,SO₁)₂(H1)₂I₄.—B'₄(H,SO₂)₂(H1)₄I₅I₈.
B'H,SO₄ 7aq: trimetric tables, insol. alcohol (Hjortdahl, J. 1879, 794).—B'₄(H,SO₂)₃(H1)₄I₁, I₈.
Isomorphous with herapathite, which it greathly resembles. Almost insol. cold alcohol (Jürgen, resembles. Almost insol. cold alcohol (Jörgenresembles. Almost insol. cold alcohol (Jörgensen, J. pr. [2] 15, 65, 418). B'_H_CO_0. S. ·042 at 15° (André); ·037 at 14°; ·05 at 16° (De Vrij, Ar. Ph. [3] 24, 1073; ·625 at 100° (A.). Ppd. by adding K₂CrO₄ to a solution of the neutral or acid sulphate. Tufts of golden needles.—B'₂H₂CrO₄ 2aq (Hesse, Ph. [3] 17, 585, 665). Becomes aphydrous et 80° but we cheath 665). Becomes anhydrous at 80°, but re-absorbs 2aq on exposure to moist air.—B'H.CrO, 7aq. Ppd. by adding K, Cr.O, to a solution of quinine in excess of dilute H.SO₄ (André, J. Ph. [3] 41, 341). Orange pp., decomposed by light, and turned brown when heated to 60°-65° or when boiled with water. More soluble than B'2H2CrO4. B'H2CO3 aq. Efflorescent needles, with alkaline reaction, deposited from a solution of quinine in aqueous CO... Sol. alcohol, insol. ether (Langlois, A. Ch. [3] 41, 89).—B'_.II,PO, 8aq. S. 127 at 10° (Hesse). Tufts of long needles.— [6] 13, 236).—B'H₂SiF₆. Got by passing SiF into a solution of quinine in absolute alcohol (Cavazzi, G. 17, 563). Minute crystals, insol. ther and CS₂, sl. sol. hot alcohol. Its aqueous solution is fluorescent.—B'₂H₃AsO₄8aq. Prisms, v. sol. hot water (Hesse).—B'₄H₃AsO₄6aq (Sestini).—B'H₃AsO₂2aq.—B'H₁FeCy₂3aq (Dollfus, Herrory 1997). A. 65, 227). -B'H_aFeCy_a 1 aq: golden plates.— B'H_aPtCy_a aq (Wertheim, A. 73, 210). Crystals.— Directory,—Billoys. Lennon-yellow monoclinic crystals (W.).—B'HCyS aq. S. 18 at 20° (Hesse, A. 181, 48).—B'₃(HCyS)₂HgCl₂.—B'₄(HCyS)₂HgCy₂.—B'(HCr(CyS),(NH₃)₂)₂2aq. Formed by ppg. a solution of the acid sulphate with Reinenbelle acid (Cheiriceae). with Reinccke's salt (Christensen, J. pr. [2] 45, 366). Red crystals, v. sl. sol. hot water.—Nitro-prusside. S. 04 (Davy, Ph. [3] 11, 756).—Cyanurates B'H₂C₁N₂O₃ 9aq. [237]. Sl. sol. hot water (Claus, J. pr. [2] 38, 227).—B'(H₂C₁N₂O₃)₂ 7aq. [213°]. — Oxalates. —B',H₂C₂O₄ 6aq. S. 1 at 10°. Prisms (Hesse, A. 176, 218; cf. Regnault, A. 26, 37).—B'H₂C₂O₄ 3aq. [a] = -131°.—B'HOAc. [140°]. Long needles, v. sol. hot water (R.).—B'Cu(OAc)₂. Green crystals (Skraup, M. 2, 611).—Chloro-acetate B'C₂H₄CiO₂ 2½aq. S. 1·6 at 21° (Mazzara, G. 13, with Reinccke's salt (Christensen, J. pr. [2] B'C₂H₃ClO₂ 23aq. S. 1.6 at 21° (Mazzara, G.13, 525).—Di-chloro-acetate B'C₂H₂Cl₂O₂ 2aq. S. 24 at 22°.-Formate: colourless needles (Bonaparte, J. Chim. Med. 18, 680). - Valerate B'C,H₁₀O, 1½aq (Bonaparte, J. Chim. Med. 18, 680; 19, 330; Chatin, J. Ph. [4] 1, 268).—B'C,H₁₀O, (Stalmann, A. 147, 132; Schmidt a. Sachtleben, A. 193, 100). S. 9 in the cold; 2.5 at 100° (Wittstein, Repert. 87, 295; Landerer, 118°]. Yellow powder (Mazzara, G. 18, 868).-

N. Br. Arch. 119, 240). — Succinate B'C,H,O, 8aq. S. 1 at 10°. Prisms, v. sol. hot water.—Tartrate B'2C,H,O,2aq. Crystalline powder (Hesse, A. 243, 134; cf. Arppo, J. pr. 53, 2014). Bid NO. 2. (Posture J. 1853, 421). 334).—B'C₄H₄O₈aq (Pasteur, J. 1853, 421). The levo tartrate is more soluble than the dextro-tartrate, and has a different crystalline dextro- tartrate, and has a different crystalline form.—BC,H,(SbOH)O_a2aq. Resin (Clarke, B. 15, 1540).—Citrate B'₂C₆H₆O, 7aq. S. 11 at 12° (Hesse); 44 at 100³ (Mandelin, J. 1879, 796; Scribani, G. 9, 284).—B'₂C₂H₆O₄: minute prisms. S. 11 in the cold; 2·4 at 100°.—Bmall prisms. S. 16 in the cold, 2·6 at 100°.—Chloro-crotonate B'C,H,ClO₂[201°]. Sl. sol. ether (Daccomo, J. 1884, 1385).—Trich lograpsubants B'C, H Cl. O... [140°]. Trichlorocrotonate B'C,H,Cl₂O₂ [140°]. Trichlorocrotonate B'C₃H₃Cl₃O₃. Sl. sol.

Tri-chloro-lactate B'C₃H₃Cl₃O₃. Sl. sol.

B'C₃H<sub>Br₂O₃.

Noodles</sub> ether.—Di-bromo-pyruvate $B'C_sH_sB_TQ_s$. [93°] (D.). — Mucate $B'_2C_sH_{10}O_s$. Needles (Ruhemanna. Dufton, C.J.59,754).—Ben zoate B'HOBz. S. 27 at 10°. Small prisms. -Sali-B'HOBZ. S. 27 at 10°. Small prisms. - Sall-cylate B'C,H_O₂. S. 44 at 16°. S. (ether) 83 at 16°. Prisms (from alcohol). — Melitate B'C,H_O₁₂. Crystalline powder, v. sl. sol. cold water (Karmrodt, A. 81, 170). — Tannates B'(C₁₁H₁₀O₃), 4aq and B'(O₁₁H₁₀O₃), 8aq (Jobst, Ar. Ph. [3] 12, 331; Neumann, Fr. 28, 664).—
Macongate B'CH O. Crystala (Austen. Ph. Meconato B'C,H,O,. Crystals (Austen, Ph. [3] 3,1016).—Urate B'C,H,N.O,. Minute prisms. S. 117 in the cold, 2.7 at 100°. S. (alcohol of S.G. 823) 063 in the cold, 2.2 on boiling (Elderhorst, A. 74, 77; Andrew, Pharm. Viertelj. 10, horst, A. 74, 77; Andrew, Pharm. Viertelj. 10, 382). Doxtro-tropate. [187°]. — Lawotropate. [187°]. — Lawotropate. [188°] (Ladenburg, B. 22, 2590). Dextro-iso-propyl-phenyl-glycollate [193°]. S. 18 at 19°; S. (alcohol) 1·44 at 20°. [a]_b = -79° . — Lawo-iso-propyl-phenyl-glycollate [205°]. S. 09 at 15°; S. (alcohol) 54. [a]_b = -118° (Fileti, J. pr. [2] 46, 560). Compound with benzene B'C₄H_a. Needles (from benzene) (Oudemans, J. 1874, 867).—Compound with toluene B'C,H_a. Needles. — Compounds with phenol

Needles. — Compounds with phenol B'PhOH. Crystals (from alcohol). S. 25 at 16° (Romai Z 1917 200). (Romei, Z. [2] 5, 383; Jobst, N. R. P. 24, 193). — B'_H_Cl_PhOH 2aq: prisms. S.1 at 15° (Jobst a. Hesse, A. 180, 248).—B'H_SO_PhOH 2aq (Hesse, Hesse, A. 180, 248).—B'H.SO, PhOH 2aq (Hesse, Pharm. Zeit. 34, 191).—B'H.SO, PhOH aq. S. 147at15°. Prisms.—B'₂H.SO, PhOH 6aq (Cotton, Bl. [2] 24, 535).—Compound with tribromo-phenol B'C, H.Br.O. Silky needles (from alcohol) (Purgotti, G. 16, 528).—Compound with anethole B'₂C, H.O. 2aq. Monoglinic crystals (from ether). sl. sol. cold alcohol clinic crystals (from ether), sl. sol. cold alcohol (Hesse, A. 123, 382). Compound with (Hesse, A. 123, 382). Compound with eugenol B'C₁₀H₁₂O₂. [110°]. S. (ether) 8.5 at 10°. Long silky prisms (Hesse, A. 185, 329). — Compound with pyrocatechin B',C, H, O, H, SO, aq: colourless needles (Hesse, C. C. 1889, 519).—Compounds with resorcin C. 1857, 319).—Compounds with resortin B'C_uH_uO₂H_sO₄ aq: needles (Malin, A. 138, 77).

—B'₂C_uH_uO₂H_sSO₄ aq (Hesse).—Compound with phloroglucin B'C_uH_uO₂H_sSO₂aq: stellate groups of needles (Hlasiwetz, Z. [2] 1,613).

—Compound with oroin B'C_uH_uO₄H_sSO₄aq. Needles (Hlasiwetz a. Barth, A. 134, 290; 138, 77).-Compound with chloral B'C.HCl.O. [149°]. Amorphous, sl. sol. cold alcohol (Mazzara, G. 13, 270).—Compound with m-nitrobenzoic aldehyde B'C, H, (NO.). CHO. [118°].

nitro - camphor Needles. [c. 131°]. with Compound $B'(C_{16}H_{16}(NO_2)O)_2$ aq. Needles. [c. 131°]. [a]_D = +46° in a 2.7 p.c. alcoholic solution Cazeneuve, Bl. [2] 49, 97).—Compound with urea B'CON,H,H,Cl, 5aq. S. 6. Small prisms (Drygin, C. C. 1878, 622; 1881, 245).—Com-(Drygn, C. C. 18/8, 622; 1861, 245).—Compounds with quinidine B'C₂₀H₂₁N₂O₂2\$aq.—B'C₂₀H₂₁N₁O₂O₄H₃2aq (Wood a. Barret, C. N. 45, 6; 48, 4; Hesse, A. 243, 146).—Compound with hydroquinidine B'C20H26N2O2 2 aq: slender white needles, v. sl. sol. water, m. sol. ether.—Compounds with cinchonidine B'2C₁₉H_{2N}O. Rhombohedra, very slightly sol. ether (Hesse, A. 243, 131).

—B'7C₁₉H₂₂N₂O. Crystals (from alcohol).—
B'₁(C₁₉H₂₂N₂O)₄(H₂SO)₃ 20aq. S. 597 at 15°. Needles.—B'₂(C₁₉H₂₂N₂O)₄(C₁H₂O)₃ 6aq.—
B'₂(C₁₉H₂₂N₂O)₄(C₁O)₃ 18aq: crystals.—
B'₂(C₁₉H₂₂N₂O)(H₂CO)₃ 6aq (?). Long colourless needles.—Compounds with cupreine B'C₁₉H₂₂N₂O 4aq. [177°]. [a¹_D = -236°. Trimetric prisms (Howard a. Hodgkin, C. J. 41, 66; Hesse, A. 225, 98; 226, 242; 230, 72). Its solution in diluth H₂SO₄ shows blue fluorescence.—B'C.H.—N.OH. PtCl. 2aq: orange-red prisms. sol. water, m. sol. ether.-Compounds with Boltubal Hi unit; 11,354, shows the hadrened reserved.

B'C₁₉H₂₂N₂OH₄PtCl₃ 2aq: orange-red prisms.

B'C₁₉H₂₂N₂OH₃SO₄6aq: six-sided prisms. S. 3

at 100°.—B'C₁₉H₂₂N₂OC₄H₄O₄ 2aq: needles.

Acetyl derivative C₂₀H₂₁AcN₂O₂. [108°].

Formed by heating quinine with Ac₂O (Hesse,

A. 205, 317). Prisms, sol. alcohol and chloroform, sl. sol. ether. $[a]_{\rm p}=-54^{\circ}$ in a 2 p.c. solution in alcohol (of 97 p.c.) at 15°. $[a]_{\rm p}=-115^{\circ}$ in presence of 3HCl. Decomposed by alcoholic potash into quinine and HOAc.—B'H, PtCl, 2aq.

Potasi mod difficult 1103.0. $= 11_{2} \text{Tr} C_{9} \text{ 2ad}$. $-B'(\text{HaCl}_{4})_{2}$ aq: yellow flocculent pp. Propionyl derivative $C_{20}H_{22}(C_{3}H_{2})\text{N}_{2}O_{2}$. $[129^{\circ}]$. Six-sided prisms, sol. ether and alcohol. $[a]_{0} = -100^{\circ}$ in a 2 p.c. solution at 15° (Hesse). $-B'H_{2}\text{PtCl}_{6}$ 2aq. -

B'(HAuCl₄), 2aq: yellow amorphous pp.

Benzoyl derivative C₁₀H₂₃BzN₂O₂. Amorphous (Schützenberger, C. R. 47, 334).—
B'H.PtCl₆.

Methylo-iodide B'MeIaq or C₁₀H₁(OMe)N.C₂H₁,NMeIO (Grimaux, Bl. [3] 7, 573). [233°-236°]. Formed by boiling quinine (1 mol.) with MeI (6 mols.) in MeOH (Streeker, 4. 91, 164; Claus a. Mallmann, B. 14, 76). Formed also from cupreïne, NaOEt and MeI (Hesse, A. 266, 240). Colourless needles (from water), v. sol. hot water and alcohol. Not attacked by alkalis in the cold. Boiling KOHAq or moist Ag₂O converts it into methyl-quinine C₂₂H₂₂MeN₂O₂, an oil which yields an amorphous hydroiodide, crystalline B'H₂PtCl₈ aq (Hesse) or B'H₂PtCl₈ 2aq (Lippmann, M. 12, 512), and C₂₂H₂₂MeN₂O₂MeI aq crystallising in needles, decomposed at 218°.

B'MeI_s. Methylo-periodides methyto-personates B'Mel₃. Black needles (Jörgensen, J. pr. [2] 3, 145; 14, 261).—
B'2Me_I_4L_5O_4. Reddish-brown needles (from alcohol).—B'2Me_I_4H_5O_4. Brown plates.—
B'4Me_I_1_52H_5O_4. Almost black laminæ.—
B'4Me_I_22H_5O_4. Almost black needles with green lights.

green lustre.

Methylo-chloride B'MeCl aq. [182°]. Needles. B'2MeHPtCl, : orange prisms. [126°].

Methylo-bromide B'MeBr aq. Siender needles, sl. sol. cold water.

 $B'Me_2I_2$ 3aq. Di-methylo-di-iodide [158°-162°]. Formed by heating B'Mel with

MeI and MeOH in sealed tubes at 100°. Got also. together with B'MeI from cupreïne by the action of NaOMe followed by MeI (Hesse, A. 266, 240). Yellow tables (from water). Converted by cold NaOHAq, or better NaOH in MeOH, into a resin and a smaller quantity of a yellow crystalline body. S. (boiling MeOH) 1, melting about 280°, sol. acids and reppd. by alkalis as a jelly. Its solutions are yellow with green fluorescence. A similar body is got by the action of alkalis on the methylo-iodide of methoxy-quinoline (obtained from quinine). - B'Me2PtCla 2aq. -B'2MeAuCl.

Ethylo-iodide B'Etlaq (Howard, C. J. 26, 1180). [211°]. Trimetric needles (from ether), with very bitter taste. Lævorotatory.

—B'EtI,: black needles.

Ethylo-chloride B'EtCl 3aq. needles.—B'EtHPtCl_s: yellow pp. Ethylo-bromide B'EtBr 2aq.

Ethylo-sulphates B'2Et2SO4 8aq.-B'EtHSO, 2aq: needles, v. e. sol. water.

Ethylo-cyanide B'EtCN. [90°]. White necdles (Claus a. Merck, B. 16, 2746).

Di-ethylo-di-iodide B'Et₂I₂3aq. [115°]. Prepared by heating quinine with EtI and alcoholic potash (Skraup, M. 2, 610). Monoclinic tables, sol. alcohol, insol. ether.

Methylo-ethylo-di-iodide B'MeEtI, aq. [208°]. Formed by boiling B'MeI with EtI and alcohol (Claus, B. 14, 76). An isomeride [157°-160°] is got from B'EtI and MeI.

Benzylo-chloride B'C,H,Cl. Amorphous. B'(C,H,)HPtCl_a 2aq: crystalline (Mazzara, G. 13, 530).—B'(C,H,),PtCl_a: yellow powder.

Tolyl-quinine C₂₉H₂₂(C,H,)N₂O₂. Two modi-

fications are formed by heating quinine with otoluidine, and two from p-toluidine. The o and p (a) modifications form oils soluble in ether; the o and p (β) modifications form amorphous yellow powders insoluble in ether, soluble in chloroform and alcohol. B'aH,Cl,PtCl,aq: ycllow crystalline powders (Claus a. Bottler, B.

Quinopropyline C₂₄H₂₈N₂O₂. [164°]. Got by heating sodium-cuproïne with PrNO₄ and PrOH at 110° (Grimaux a. Arnaud, Bl. [3] 7, 310). White powder.—B'_H,SO, 1 aq. Silky needles. [224°]. $[a]_D = 229$ at 22° .

Quinoisopropyline [154°]. Formed in like manner from PrNO₃.—B'₂H₂SO₄aq. S. 3 at 10°.

 $[a]_D = 229^{\circ}$.

Quinoamyline C₂,H₃₂N₂O₂. [167°]. Formed from sodium-cupreïne and amyl chloride in amyl alcohol at 105°. Amorphous.—B'.H.SO, 2aq. Needles. S. 025 at 11°. Its solution in dilute H2SO, fluoresces.

Quinine sulphonic acid C20H23(SO3H)N2O2 [209°]. Formed by moistening quinine tetrasulphate with Ac2O, and treating the product with hot water (Hesse, A. 267, 141). Small white prisms (containing aq when air-dried).

[a]_D = -182° in a 2 p.c. solution containing HGl
(3 mols.).—H₂A'₂H₂PtCl₂ 8aq.

Quinine (Iso)-sulphonic acid

C20H23N2O2(SO3H). Formed from quinine and furning H2SO, (Hesse, A. 267, 138). V. sol. water, forming a slightly acid lavorotatory solution with blue fluorescence. Gives a dark-green colour with chlorine-water and NH,Aq.-HA'HAuCl,: yellow flocculent pp.

Apoquinine $C_{10}H_{22}N_2O_2$. [160°]. [α]_D = -178° in a 2 p.c. solution of alcohol (of 97 p.c.) at 15°. $[a]_p = -247^\circ$ in water containing 3HCl. Formed by heating quinine or cupreïne with HClAq at 140° (Hesse, A. 205, 323, 341; 230, 65). Amorphous powder (containing 2aq), sol. alcohol, ether, CHCl,, and hot water. A solution of its sulphate shows no fluorescence. Chlorine-water and ammonia give a dark-green colour in the cold. The sicoholic solution gives a dark brownish-red colour with FeCl₃. Fuming HClAq at 150° forms C, H, ClN, O, 2aq [160°], which gives the salts B'H,Cl, 3aq, B'H,PtCl, 2aq, and C₁₀H₂₁Ac₂ClN₂O₂ [184°]. Salts. — B'H₂PtCl₈ 3aq. — B'HI.

Small crystals (Lippmann a. Fleissner, M. 12, 331).

Acetyl derivative C10H20Ac2N2O2: amorphous powder, sol. ether and alcohol.

Isoapoquinine C₁₉H₂₂N₂O₂. [176°]. Formed by the action of boiling alcoholic potash on C, H22N2O23HI [238°] (v. QUININE, Reaction 8): Crystalline (Lippmann a. Fleissner, M. 12, 331). -B'H2PtCls aq: granules, sl. sol. water.

Isoquinine $C_{\infty}H_{24}N_2O_2$. [186°]. $[a]_D = -181^\circ$ in a 4 p.c. solution. Formed from the compound C₂₀H₂₄N₂O₂3HI [230°] (v. QUININE, Reaction 9) with alcoholic potash (Lippmann a. Fleissner, M. 12, 332). Needles (containing aq), v. e. sol. benzene, sl. sol. ether, v. sl. sol. boiling water. Coloured green by chlorine-water and ammonia. -B'HCl 2aq: needles, v. sol. water. -B'2HCl, m. sol. water.—B'II,PtCl_e: yellow crystalline pp.— B'2H2SO 10aq : needles, v. e. sol. water.— B'AgNO,: needles.

#-Quinine C₁₂H₂₄N₂O₂. [191°]. Formed, together with nichine C₁₂H₂₄N₂O₂ (?), by heating quinine hydroiddie with alcoholic potash B. 25, 2911). Lævorotatory. (Skraup, B'HCl, B'HNO, and B', HNO, all sl. sol. water and readily crystallised.

Chinene or Quinene v. QUINIENE, vol. ii. p. 181.

Homoquinine v. Cinchona Bases.

QUININIC ACID v. Methyl derivative of (B, 3)-OXY-QUINOLINE CARBOXYLIC ACID.

QUINISATIC ACID C.H. (NH.). CO. CO. CO. H. o-Amido-benzoyl-glyoxylic acid. Formed by oxidation of (Py. 1,2,3)-tri-oxy-quinoline with FeCl. (Bacyer a. Homolka, B. 16, 2219). Yellow prisms, v. sol. water. On reduction with zincdust and HOAc and exposure of the filtrate to the air it forms a dark-blue colouring matter.

Anhydride C,H, CO.CO. [255°-260°].

Formed by heating the acid at 120°. Red crystals, forming a red solution in alcohol. Readily combines with water, with re-formation of the acid. Dilute NaOHAq forms a yellow solution, very quickly becoming colourless.

NaOEt gives a body crystallising in indigo-blue needles. Gives an oxim $C_6H_4 < CO.C(NOH)$ erystallising in orange prisms [208°].

QUINITANNIC ACID. An acid occurring in cinchona bark (Schwarz, J. pr. 56, 76; cf. Pelletier a. Caventou, A. Ch. [3] 15, 837). Hygroscopic yellow mass. Its alkaline solutions absorb oxygen. Converted by boiling dilute acids into glucose and a brownish-red powder C28H22O14, which gives acetic and protocatechnic acid when fused with potash (Rembold, A. 143, 270).

QUINITE C.H.,O. i.e.

 $CH(OH) < CH_2 \cdot CH_2 \cdot CH(OH)$. Hudroguinons hexahydride. Formed, by reduction with sodium. amalgam in a current of CO, from the product of the action of dilute H.SO, on the dihydride of di-oxy-terephthalic ether (succinyl-succinic ether) (Bacyer, B. 25, 1037, 1840). V. sol. water and alcohol. Occurs in two modifications, trans [144°] and cis [90°], which yield acetyl derivatives melting at 106° (trans) and 32° (cis). Both acetyl derivatives boil at 244°. Quinite is converted by HBr into di-bromo-benzene hexahydride (trans [114°], cis an oil), which on heating with quinoline give oily benzene dihydride (81°), which forms a tetrabromide [182'].

QUINIZARIN v. DI-OXY-ANTHRAQUINONE.

Substances supposed to be QUINIZINE. derived from the hypothetical quinizine were subsequently found to be derivatives of phenyl-pyrazole. Thus oxy-methyl-quinizine is oxyphenyl-methyl-pyrazole (q. v.).
QUINOL v. Hydroquinone.

QUINOLIC ACID Coll, N.O. . Got by oxidation of cinchonine with HNO, (Weidel, A. 178, 91; B. 12, 1152). Woolly crystals, almost insol. water, v. sl. sol. alcohol, sol. HClAq. Alkalis give a transient crimson colour. Br and water at 180° give hexa-bromo-quinoline. HNO, at 170° forms cinchomeronic acid.—AgA'.—
11A'HCl.—H₂A'_H_PtCl_u: orange needles.

QUINOLINE C_yH₁N i.e.

CH:CH.C.CH:CH. Chinoline. Leucoline. Mol. CH:CH.C.N :CH. w. 129. (237.5°) (Young, C. J. 55, 485); (234°) (Schiff, B. 19, 566); (241° cor.) (Kretschy, M. 2, 80). S.G. 2 1.106 (O. de Coninck, Bl. [2] 37, 208); 2 1·108 (Skraup). S.V. 139·8 (Schiff). Vapour-pressure: Young. Heat of neutralisation: Colson, A. Ch. [6] 19, 409. Absorption of ultra-violet spectrum: Hartley, C. J. 41, 47. Occurs in coal-tar (Runge, P. 31, 68; Hofmann, A. 47, 76; 53, 427; 74, 15; Greville Williams, Tr. E. 21 [2]; [3] 377; O. Fischer, B. 16, 720; Jacobsen a. Reimer, B. 16, 1084).

Formation.-1. By distilling quinine, cinchonine, or strychnine with potash (Gerhardt, A. 42, 310; 44, 279; O. de Coninck, A. 42, 310; 44, 279; O. de Coninck, C. R. 94, 87; Bl. [2] 35, 296). Quinoline free from homologues is got from cinchonine by treatment with potash and CuO (Wyschnegradsky, B. 13, 2318). -2. By passing allyl-aniline over heated PbO (Königs, B. 12, 453).—3. From hydrocarbostyril (vol. i. p. 180) by treatment with PCl, and reduction of the product with HI and HOAc (Baeyer, B, 12, 1320) .- 4. By distillation of acrolein-aniline (Königs, B. 13, 911) .-5. By distilling anil-uvitonic acid with sodalime (Böttinger, B. 13, 2165).-6. By heating a mixture of nitro-benzene, aniline, glycerin, and H.SO, for three hours with inverted condenser (Skraup, M. 1, 316; 2, 139, 535).—7. By heating its carboxylic acids with lime. -8. By adding a few drops of NaOHAq to a cold dilute solution of equimolecular quantities of o-amido-benzoic aldehyde and acetic aldehyde (Friedländer a. Gohring, B. 16, 1833).—9. By heatingthe hydrochloride of quinoline tetrahydride with water and Hg(OAc), at 150° (Tafel, B. 25, 1623).—10. By fusing methyl-acetanilide with ZnCl, at 290° (Pictet, B. 23, 1903).

Preparation.—A mixture of aniline (38 pts.), glycerin (120 pts.), nitro-benzene (24 pts.) and H₂SO₄ (100 pts.) is heated with inverted condenser. Potash is then added, and the base distilled over with steam and fractionally distilled. It may be further purified by means of the acid sulphate and freed from aniline by oxidation or by treatment in acid solution with NaNO₂. The

yield is 60 p.c. (Skraup).

Properties.—Colourless liquid with peculiar odour, slowly becoming yellow. V. sl. sol. water, miscible with alcohol, ether, and GS₂. Quinoline is very hygroscopic, forming the hydrate (C,H,N),3aq, which becomes turbid on warming (Hoogewerff a. Van Dorp, R. T. C. 1, 1, 107). It is antiseptic, antipyretic, and antizymotic (Donath, B. 14, 178). Quinoline separated from solutions of its salts dissolves in excess of NH. or ammonium carbonate, but not in NaOH or Na CO. Iodine in KI gives a brown pp., insol. HClAq. Phosphomolybdic acid a yellowish-white pp., sol. NH,Aq. Picric acid a yellow amorphous pp. HgCl. a white pp., sol. HClAq. K2HgI, a yellow amorphous pp., changed to yellow needles on adding HCl. K.Cr.O, gives crystals, sol. excess. Potassium ferrocyanide an amorphous orange pp. (Donath, B. 14, 1769). On shaking with cone. CuSO, Aq a green pp. (CuSO, 4(CuO, H,), 4aq is got (Borsbach, B. 23, 924; cf. Lachovitch, M. 10, 884). NaOBr gives no reaction (Deniges, C. R. 107, 662). Quinoline forms very soluble crystalline compounds with NaHSO₃ (Brunck a. Graebe, B. 15, 1785). It combines with iodoform (Rhoussopoulos, B. 16.

Reactions.—1. On passing through a red-hot tube it yields (β)-diquinolyl (Zimmermann a. Müller, B. 17, 1965).—2. On boiling with sodium or sodium-amalgam it is converted into 'diquinoline,' which forms a scarlet hydrochloride which dyes silk a transient orange (Greville Williams, Pr. 31, 536; C. N. 37, 85).—3. Reduced by tin and HClAq to quinoline tetrahydride (244°) (Wyschnegradsky, Bl. [2] 34, 339).—4. Zincdust and NH, Aq or alcohol and sodium-amalgam give the tetrahydrides of quinoline and of diquinoline (Königs, B. 14, 99) .- 5. Oxidised by bleaching-powder or other hypochlorites to oxyquinoline (carbostyril) and chloro-oxy-quinoline (Erlenmeyer, B. 19, 489; Einhorn a. Lauch, A. 243, 342). Chlorine passed into its solution in HOAc forms tri-chloro-oxy-carbostyril.—6. On heating with SbCl, at 170°-400° and passing in chlorine, the products are C₂Cl₆ and C₆Cl₆ (Smith a. Davis, C. J. 41, 413).—7. Bromine (2 pts.) added to a mixture of quinoline (1 pt.) and water (3 pts.) forms the tetrabromide C.H.NBr., which crystallises from chloroform in very unstable red needles, and is converted, by heating with alcohol, into C_bH.NBr₂HBr [86°] crystal-lising in red prisms, insol. chloroform, v. sol. alcohol and ether, decomposed at 180° into HBr and bromo-quinoline-hydrobromide (Grimaux, Bl. [2] 38, 125; C. R. 95, 85). Bromine added to an ethereal solution of quinoline forms the dibromide C₀H₇NBr₂, yielding B'HCl [100°-105°] and B'HBr [88° cor.], which form red crystals (Claus a. Collischonn, B. 19, 2765).—8. KMnO. in alkaline solution forms pyridine dicarboxylic acid (Hoogewerff a. Van Dorp, R. T. C. 1, 1, 107; cf. Dewar, Pr. 26, 65). KMnO, and conc. H₂SO.

also give quinolinic acid. KMnO, and dilute H₂SO, form quinoline (B. 3)-carboxylic acid, diquinolyl being an intermediate product (Georgievitch, M. 12, 312).-9. H2SO, at 220° forms the (B. 4)-sulphonic acid; at 250° the (B. 2)-sulphonic acid is produced (Georgievitch, M. 8, 578, 641).-10. Oxygen passed through platinised asbestos containing quinoline and quinoline hydrochloride at 190 forms (a)-diquinolyl. Oxygen acting on a mixture of aniline and quinoline hydrochloride forms (Py. 3; B. 2)-diquinolyl and p-amido-(Py. 3)-phenyl-quinoline, while quinoline and o-toluidine hydrochloride are converted by oxygen into amido-phenyl-methyl-quinoline (Weidel, M. 8, 120; 9, 99).—11. p-Amido-phenyl-quinoline is also formed by heating quinoline hydrochloride with aniline.—
12. BzCl at 240° gives (β)-diquinolyl.—13.

Alloxan added to a solution of quinoline saturated with SO₂ forms B'C₂H₁N₂O₃SO₃H₂ orystallising in yellowish prisms (Pellizzari, A. 248, 150).—
14. SiCl, forms (C₉H₂N)₂SiCl, (Harden, C. J. 51, 40). SiF₄ forms (O₉H₂N)₂SiF₄, crystallising in Arguer Arguer (176).—15 needles (Comey a. Jackson, Am. 10, 176).—15. Nitroso-di-methyl-aniline and hydrogen cyanide form B'(C₆H₄(NO).NMo₂)₂HCy, crystallising in golden plates (Lippmann a. Fleissner, M. 6, 543). — 16. Glycerin dichlorhydrin forms (C₆H₄N)C₂H₄Cl, which is deliquescent and forms (B'C₈H₃Cl)₂PtCl, and B'C₈H₃AuCl, —17. Ethylene chloride at 100° forms B', C, H, Cl., orystallising in needles, yielding B', C, H, PtCl, (Rhoussopoulos, B. 16, 879).—18. Ethylene bromide (1 mel.) heated with quinoline (1 mol.) at 80° forms the brome-ethyle-bromide B'BrC₂H₄Br, crystallising from alcohol in needles and yielding B'ClC2H1Br and (B'ClC2H,Br)2PtCl, (Berend, B. 14, 1349). Ethylene bromide (1 mol.) with quinoline (2 mols.) at 40° forms B'C₂H₄Br₂ aq crystallising from alcohol in needles.—19. By heating quinoline (16 g.) with glycolic chlorhydrin (10 g.) and water (10 c.c.) for 3 days at 100° there is formed B'Cl.C.H.OH, crystallising from alcohol-ether in splendid prisms (Wurtz, Pr. 33, 452; C. R. 95, 263; 96, 1269). It is hygroscopic, v. sol. water and alcohol, insol. ether. On boiling with moist Ag.O it forms a caustic liquid that soon turns crimson. It yields B'(C.H.OH)AuCl,, crystallising in minute pointed hexagons, and also B'(C,H,OH)Cl6HgCl,, and (B'(C,H,OH)Cl),PtCl,. 20. Iodoform (1 mol.) heated with quinoline (2 mols.) for 8 days at 100° forms B', CH, I, crystallising in long needles [132°] (Rhoussoby AgCl into B'₂CH₂Cl₂ [168°], which gives B'₂CH₂PtCl₆. Iodoform (1 mol.) added to quinoline (3 mols.) in ethereal solution forms B'₃CH₄. crystallising in needles [65°], not affected by AgCl.—21. Chloro-acetic acid forms quinolinebetaine C₁₁H₃NO₂ [171°], which separates from alcohol in thick crystals (containing aq) and forms (C₁₁H₃NO₂).H.PtCl₄2aq (Gerichten, B. 15, 1254; Rhoussopoulos, B. 15, 2006).—22. Chloroacetic ether forms CuH, NCl. CH2. CO2Et crystallising in needles, v. e. sol. water, converted by lising in needles, v. e. sol. water, converted by moist Ag.O into quinoline. It yields the salt (C₁₃H₁₄NO₂)₂H₂PtCl_{e*} — 23. Chloral in ether forms C₂H₃NC₄HCl₄O aq [66°], crystallising from benzene (Rhoussopoulos, B. 16, 881). It is insol. water and decomposed by alcohol. It yields (C₂H₃NC₄HCl₄O aq).3PtCl₂ — 24. Reservin at 100° forms (C,H,N),C,H,O,, [102°], S. 25 in the cold (Hock, B. 16, 886). It crystallises from dilute alcohol in silvery plates, decomposed by HClAq.-25. Phthalic anhydride at 150° forms 'quino-phthalone' C17H2NO2 [235°] (Traub, B. 16, 297).

10, 297).

Salts. — B'HCl. [94°]. Deliquescent nodules, v. e. sol. alcohol, chloroform, and hot ether (O. de Coninck, Bl. [2] 37, 208).—

B'₂H₂PtCl₄ 2aq [225°] (Skraup); [218°] (Lellmann, A. 237, 323).—B'₂H₂PtCl₄ aq. S. 07 at 11°.—B'₂PtCl₄; insoluble powder.—B'₂H, PtCl₄. B'HAuCl, Canary-yellow needles.—B'HCdCl₃aq. —B'CdCl₂: white pp.—B'HgCl₂. Pearly plates (Bromeis, 4, 52, 136).—B'₂H₂H₂Cl₁2aq. [91°]. (Bromeis, A. 52, 136).—B.,H.,HgCl, 2aq. [91].
Monoclinic crystals.—B',H.,PdCl,. Crystals.—
B'H,SnCl, 2aq: needles.—B'HSnCl,. [127].
Thin needles.—B',H.,SnCl,. [above 240].—
B',H.,UrO,Cl,: yellow prisms.—B'SbCl,.—
B',HB,BiCl,.—B',H,ZnCl,.—B',ZnCl,.—
B'HSlCl,.—B',H,ZnCl,.—B',ZnCl,.—
B'HCHCl. [118] (Östermayer). Yellow pp., converted by ammonia into explosive B'NH2I (Dittmar, B. 18, 1613).—B'ICl. [160°]. Small white needles (Pictet a. Krafft, Bl. [3] 7, 73).— B'Br.HCl. [100°-105°]. Orange crystals (Claus, B. 19, 2766). - B'HMnCl3: rose-red needles (Borsebach, B. 23, 433).—B'HFeCl₄. [150°]. Formed by adding HCl to a solution containing quinoline and FeCl₃ (B.). Small needles, decomposed by boiling water.—B'₂CoCl₂: blue triclinic crystals.—B'_Cu(OAc), nearly black crystals.—B'Cu(OAc), nearly black crystals.—B'Cu(OAc), nearly black crystalline powder.—B'_ZnI_z: white powder, sl. sol. cold water.—B'₂ZnBr₂.—B'CdBr₂.—B'CdI₃..—B'₂CaI₃. —B'HgBr₂. [201²].—B'HgI₂. [168²].—B'Br₃. [92°-100°]. Red crystals (Lubavin, *J. R.* 18, 434).—B'Br., Red needles.—B'Hbr., [86°].—B'Br., HCl. [100° 105°].—B'I₂. [90°]. Formed by adding I to a solution of quinoline in CS. (Claus a. Istel, B. 15, 824). Dark-green lustrous needles.—B'HI₄. [67°]. Ppd. by adding I in KI to a solution of quinoline sulphate (Dafert, M. 4, 509). Green crystalline pp., sol. alcohole and benzene.—B'H.SO. [164°]. S. (alcohol) 2 at 18°; 11 at 78° (Krakau, J. R. 17, 364). Deliquescent crystals.—B'.H.Cr.O., [c. 167°]. Yellow needles (from hot water). S. 36 at 10°. -B'HNO3. Needles (from alcohol), v. sol. water, insol. ether. - B'2AgNO3: needles. -Whete, 1000, 100, Silky needles (from alcohol). Decomposes at Shky heedes (from account). Decomposes at 100° (Williams).—B'₂HgCy₂: long needles (from water) (H. Schiff, A. 131, 112).—Tartrate B'₃4C₄H_aO₃. [125°] (Friese, B. 14, 2805).—Cyanurate B'₃H₃C₃N₃O₃. Crystals (Claus, J. pr. [2] 38, 226).—B'HSCy(Cr(SCy)₃NH₃). Red lamelle, sl. sol. hot water (Christensen, J. pr. [2] 45, 365). - Picrate: [203]. - o-Oxybenzoate B'C,H,O,. Crystalline powder.

Alkylo-iodides. According to Decker (B. 24, 690) the alkylo-iodides B'RI are converted by alkalis into the hydroxides B'ROH which are readily oxidised by the air to crystalline oxy-v-alkyl-quinolines C₆H₄ CH:CH which melt about 100°. The cyanines may be considered as derived from one molecule of alkylquinoline and one molecule of oxy-v-alkyl-quinoline. The alkylo-hydroxides are converted by warming with alcohols R'OH into compounds B'ROR'.

Methylo-chloride B'MeClaq. On heating with ZnCl, at 180° it is converted into a base C₂₀H_mN₂O [72°-75°] (above 360°), crystallising in large trimetric prisms, and yielding a hydrochloride [112°] and the double sults $C_{20}H_{-20}N_{.}OHAuCl_{+}$ and $(C_{20}H_{-20}N_{.}O)_{.}H.PtCl_{+}$ [190°] nearly insol. water (Ostermayer, B. 18, 593).—B',Me,PtCl_{+} [230°]. Yellow plates.—B'MeAuCl_{+} (20°) — B'McCllCl. [112°]. Formed by adding ICl to the methylo-chloride in aqueous solution. Large yellow plates.

Methylo-tribromide B'MeBr₁. [123°]. Orange-red plates. Converted by picric acid solution into B'MeOC₁H₁(NO₂)₂ [164°]. Methylo-iodide B'MeI. [73°] (La Coste, B. 15, 192; Pictet, B. 23, 1903). Large crystals. Converted by moist Ag₂O into a strongly alkaline solution of the hydroxide B'MeOH. Aqueous NaOH in the cold converts B'McI into the oxide B'2Me2O, a white powder, reconverted by HI into B'MeI (possibly oxy-v-methyl-quinoline) (La Coste; Claus, B. 15, 475; Bernthsen, B. 18, 29; Decker, B. 24, 690). Potash, even in cold aqueous solution, forms an oil probably containing methyl-quinoline (lepidine) (Skraup, Sitz. I'v [2] 81, 593). By the action of KOH on a mixture of B'MeI (2 pts.) and the methyloiodide of (Py. 1)-methyl-quinoline (1 pt.) there is formed di-methyl-cyanine iodide C21H19N2I, crystallising in oblong green tablets, [291], sl. sol. water, forming a reddish-blue solution (Hoogewerff a. Van Dorp, R. T. C. 2, 317; 3, 337). The alcoholic solution is violet, with green fluorescence. Its solution in acids is yellow. The aqueous solution is decolourised by CO, the colour re-appearing on boiling. corresponding $C_{21}H_{19}N_{2}Cl$ E_{30} [c. 300] forms $C_{21}H_{18}N_{2}Cl$ (H1*Cl.) and as yellow crystals. Quinoline methylo-iodide is oxidised by alkaline K₃FeCy₆ to oxy-methyl-quinoline or ν-methylquinolone C_6H_1 $\stackrel{CH}{<}$ $\stackrel{:CH}{NMe}$ $\stackrel{:CH}{CO}$ [72°] (324° at 728 mm.) (Decker, J. pr. [2] 46, 31; cf. Bernthsen a. Hess, B. 18, 37, who took it for di-methyl-diquinolyl; Ostermayer, B. 18, 591). This body is also got from carbostyril and MeI (Friedlünder a. Müller, B. 20, 2009). It deliquesces with water, forming an oil. Hydrochloride

 $[112^{\circ}]$ Ethylo-chloride B'EtClaq. [93°]. Large trimetric tables (Claus a. Tosse, B. 16, 1277).—

B'₂Et₂PtCl₆. [226°]. Yellow pp. E'thylo-bromide B'EtBr aq. metric tables. By the action of (Py. 1)-methylquinoline ethylo-bromide it is converted into diethyl-cyanine bromide C22H23N2Br or C23H22N2Br, crystallising in small needles, not melted at 290°. forming a blue solution in alcohol.

Ethylo-iodide B'EtI. [118°] (Spaltcholz, B.16, 1851); [160°] (Hoogewerff a. Dorp, R. T.C. 2, 321). Monoclinic crystals At 280° it yields (γ)-ethyl-quinoline and di-ethyl-quinoline (Reher, B. 19, 2996). Moist Ag₂O forms strongly alkaline B'EtOH, which is sol. water and resinified by atmospheric oxidation. On heating B'EtI (2 pts.) with (Py. 3)-methyl-quinoline ethylo-iodide (1 pt.) and alcoholic potash, there is formed di-ethyl-isocyanine iodide C.H.N.I

(Hoogewerff a. Van Dorp, R. T. C. 3, 344) or C₂₂H₂₈N₂I (Spalteholz, B. 16, 1851). This body forms lustrous green prisms (containing haq or } EtOH or ½ EtOH 1 haq) melting at 152°. It is insol. ether, sl. sol. water, and forms a crimson solution in alcohol. By the action of KOH on a mixture of B'EtI and (Py. 1)-methyl-quinoline ethylo-iodide there is formed di-ethyl-cyanine iodide C₂H₂N₂I [273°], crystallising in green prisms (Hoogewerff a. Van Dorp, R. T. C. 2, 317). Quinoline ethylo-iodide is oxidised by alkaline K₃FeCy₆ to C₈H₄ CH :CH NEt.CO (Decker, J. pr. [2] 47, 36), which body is also got

from carbostyril and Etl (Friedländer a. Weinberg, B. 18, 1530). Solidifies at -20° . $C_oH, NEtIHgCy_x$. [138°]. Needles (from water). $C_oH, NEtBrHgCy_z$. [155°]. Crystals (from alcohol) (Claus, A. 269, 271).

Ethylo-nitrate B'EtNO₃. [89° unc Large trimetric crystals (Claus, B. 16, 1277). [89° uncor.].

Propylo-chloride B'PrCl aq. [c. 95°] (hydrated); [135°] (anhydrous). Colourless crystals (Claus a. Collischonn, B. 19, 2504). Crystallises from chloroform in prisms (containing CHCl₂) [79°]. V. e. sol. water.—B'PrClBr₂. [85° uncor.]. Orange-red radiating crystalline mass. -B'BrClI.

[62°]. Brown crystals.

Propyl-bromide B'PrBr 2aq. [66° uncor.] (hydrated); [148° uncor.] (anhydrous). Formed by heating quinoline with PrBr and a little (10 p.c.) alcohol at 100°. Tables, v. e. sol. water and alcohol. The anhydrous crystals (obtained from absolute alcohol) are very deliquescent. Crystals obtained from chloroform (containing CHCl₃) melt at 65°-129°.—B'PrCl_Br. [c. 60°]. Formed by passing dry Cl into a solution of B'PrBr in chloroform. Small sulphuryellow plates. Unstable.—B'PrBr₄. [93°]. Formed by adding Br to the aqueous or alcoholic solution of B'PrBr. Triclinic garnet-red crystals. Yields (Py. 3)-bromo-quinoline on heating. B'PrBrl₂. [60° uncor.]. Formed by evaporating a mixture of I in ether and B'PrBr in alcohol. Lustrous brown needles. - B'PrBrI. [49°]. Slender, nearly black, needles with green

Propylo-iodide B'PrI. [145°]. yellow crystals. Not hygroscopic. Crystallises from chloroform with CHCl3, partially melting at 92°. — B'PrCl.I. [87°]. Sulphur-yellow needles.—B'PrCl.I. [145°]. Converted by long boiling with water into B'PrCl.—B'PrBr.I. [77°]. Triclinic orange tables.—B'PrBr.I. [480_580] Very unstable orange powder.—B'PrI₃. [62°]. Very stable bronzy brown prisms.—B'PrI₄. [50°]. Stable tables.

Iso-amylo-chloride B'C_sH₁₁Cl.—

 $B'_2(C_bH_1)_2P'Cl_s$. [220°]. Yellow crystalline pp. Iso-amylo-bromide B'O₂H₁₁Braq. [87°] (hydrated); [140°] (anhydrous) (Claus a. Tosse, B. 16, 1277)

 $B'C_3H_{11}I$. Isoamylo-iodide B'C,H,I. [185°]. Yellow monoclinic needles (Perkin, C. J. 14, 246; Nadler a. Merz, J. pr. 100, 129; Greville Williams, C. N. 1861, 219; Hoogewerff a. Van Dorp, R. T. C. 2, 40; 3, 352; Arzruni, R. T. C. 4, 62). Does not form cyanine on treatment with potash unless it contains the isoamyloiodide of (Py. 1)-methyl-quinoline, in which case di-isoamyl-cyanine iodide C₂₂H₃₅N₂I

[c. 100°] is produced. This body crystallises in lustrous green monoclinic crystals (containing $1\frac{1}{2}$ aq); a:b:c=2:379:1:1:669; $\beta=88^\circ$ 45'. It also forms brass-yellow crystals. It is very hygroscopic, nearly insol. ether, sl. sol. CHCl, acetone, and isoamyl alcohol. It is v. sol. alcohol, forming a deep-blue solution. Iodine converts it into C29H35N2I3 [189°], which is sl. sol. alcohol, v. sol. acetone, forming blue solu-tions. The solution of di-isoamyl-cyanine iodide in HClAq is colourless, and deposits on evaporation colourless scales of C29H35N, I2HCl. evaporation colouriess scales or $C_{2p}H_{2p}N_{2}L2HCI_{1}$, which at 100° gives off HCl, leaving bronzed $C_{2p}H_{13}N_{2}IHCI$. Moist Ag₂O forms uncrystallisable $C_{2p}H_{23}N_{2}(OH)$. Alcohol and AgCl produce $C_{2p}H_{23}N_{2}(OI)$ and corpusing in long blue prisms, and yielding $(C_{2p}H_{2q}N_{2}CI)_{2p}PtCI_{2p}$. Alcohol and AgNO₃ give $C_{2p}H_{3p}N_{2}(NO_{3})$ aq, which forms between $C_{2p}H_{3p}N_{2}(NO_{3})$ and $C_{2p}H_{3p}N_{2}(NO_{3})$. lustrous needles giving a blue aqueous solution and yielding colourless C₂₂H₂₃N₂(NO₃)2HCl and blue C₂₂H₃₃N₂(NO₃)HCl. Alcoholic ammonium sulphide converts the nitrate into reddish-yellow monoclinic crystals of C₃₈H_{s8}N₄S₃O₂, which yields $C_{a_3}H_{a_5}N_1S_2Cl_42PtCl_4$ as an orange pp. (N. a. M.). H.SO, converts di-isoamyl-cyanine iodide into $(C_{29}H_{35}N_2)_2SO_4$ 2aq, crystallising from hot water in blue needles.

Allylo-iodide B'C, H,I. [177.5°] (Pictet,

C. R. 95, 300).

Benzylo-chloride B'C,H,Cl 3aq. [65°]. iclinic tablets. It crystallises also as Triclinic tablets. B'C,H,Cl 2aq [130°] in trimetric crystals (Claus, B. 13, 2045; 16, 1279; 18, 1305). V. sol. water and alcohol, insol. ether. KMnO, oxidises it to benzyl-o-amido-benzoic acid and its formyl derivative. By treatment with KOH or Ag.O it is converted into a strong base, v. sol. water. Excess of KOH ppts. an oil which turns red in air. The benzylo-hydroxide yields quinoline on distillation (Bernthsen a. Hess, B. 18, 35). Mercuric chloride yields a crystalline pp. [142°].—(B'C,H,),PtCl_s. [246°]. Yellow pp.—B'C,H,ClBr₂. [92°]. Crystalline.—B'C,H,BrCl_s. [80°]. Yellow needles.—B'C,H,Br,. [100°]. Orange prisms.—B'C,H,BrI,. [110°]. Dark-[100°]. violet needles.

Phenacylo-bromide B'Br.CH.Bz. [1150-165°]. Needles, v. sol. water and alcohol, v. sl. sol. ether (Bamberger, B. 20, 3340).—B'HNO₃.

References .- AMIDO-, BROMO-, BROMO-AMIDO-, Bromo-nitro-, Chloro-, Chloro-nitro-, Iodo-, Nitro-, Oxy-amido-, and Oxy- quinolines.

Diquinoline v. DIQUINOLYL.

Isoquinoline C₀H,N i.e. C_cH₄<CH:OH. [23°].

(241° i.V.). Occurs, as well as quinoline, in coal-tar (Hoogewerff a. Van Dorp, R. T. C. 4, 125, 285; 5, 305).

Formation.—1. By the action of HI at 230° or of zinc-dust in a current of H at a low red heat upon the di-chloro- derivative [123°] obtained by the action of POCl, on the imide of $C_6H_4 < CH_2CO NH$ o-carboxy-phenyl-acetic acid (Gabriel, B. 18, 3470; 19, 1656, 2361; Le Blanc, B. 21, 2299).—2. Together with di-isoquinolyl, which yields B'₂H₂PtCl₄ [177°] by distilling henzylidone-ethyl-amine (Pictet a. Popovici, B. 25, 733).—3. By heating isocarbostyril or its

carboxylic acid with zinc-dust in a current of

hydrogen (Bamberger a. Kitschelt, B. 25, 1146; |

Zincke, B. 25, 1497).

Properties. - Hygroscopic tables. **Vialda** phthalic and cinchomeronic acids on oxidation by KMnO₄. Tin and HClAq give a tetra-hydride. Forms crystalline compounds with HgCl₂ and AgNO₄. Bromine in ether gives C₂H₂NBr₂, [82°], which forms very unstable C.H.NBr.HBr. [c. 133°], converted at 200° into bromo-iso-

[c. 133°], converted at 200° into bromo-isoquinoline [40°] (Edinger, J. pr. [2] 43, 191).

Salts.—B'₂H.PtCl₂2aq. [264°]. Reddishyellow crystals.—B'HAuCl₄. [225°]. Yellow needles.—B'HgCl₂. [165°]. White needles.—B'HgCl₂. [165°]. White needles.—B'HgCl₂. [165°]. Yellow needles.—B'H₂Cr₂O₇: needles.—Picrate B'C₄H₃N₅O₇. [223°]. Yellow needles.

Methylo-iodide B'MeI aq. [160°]. Flat yellowish needles. Treatment with AgCl and yellowish chloride gives (R'MeCl) PtCl [240°].

platinic chloride gives (B'MeCl),PtCl, [240°] (Claus, J. pr. [2] 38, 492). KOHAq added to B'MeI forms an oily base which yields (B'MeCl),PtCl, 6aq. Özidised by alkaline K_xFeCy, to ν -methyl-isoquinoline C,H₄ CH:CH [40°] (319°), sol. water, and yielding B'H,PtCl₆ 2aq (Decker, J. pr. [2] 47, 37). Ethylo-iodide B'EtI. [147°]. Yellowishyielding

red tables. Yields ethyl-phthalimide on oxida-

tion. Gives (B'EtCl), PtCl.

Benzylo-chloride B'C,H,Cl. water and alcohol, sl. sol. ether (Goldschmidt, M. 9, 678). Yields benzyl-phthalimide [115°] on oxidation by KMnO, in a solution kept neutral by HCl.

Phenacylo-bromide B'BrCH2Bz. [205°]. Formed from isoquinoline and ω-bromo-acetophenone dissolved in benzene (G.). Prisms (from alcohoi), v. sol. water. AgNO3 forms B'NO_s(CH₂Bz) crystallising in needles.

Diquinoline v. DIQUINOLYL.

QUINOLINE (B. 1)-CARBOXYLIC ACID

ÇH:C(CO₂H).C.CH:ÇH Quinoline ana-carb-CH:CH ___ C-N:CH oxylic acid. Quinoline-m-carboxylic acid.

[357°].

Formation.-1. Together with a smaller quantity of the (B. 3)-acid by heating m-amidobenzoic acid with glycerin, H.SO., and m-nitrobenzoic acid (Schlosser a. Skraup, M. 2, 518; 7, 519) .- 2. By saponifying its nitrile, which is got by distilling sodium quinoline (B. 1)- or (B. 4)sulphonate with KCy (Bedall a. Fischer, B. 14, 2574; 15, 683, 1980).—3 By heating quinoline (B. 1,4)-di-carboxylic acid (Skraup a. Brunner, M. 7, 153).

Properties .- White crystalline powder, sol. dilute acids and alkalis, insol. ether and benzene,

v. sl. sol. water and alcohol.

Salts.-HA'HCl 11aq: white needles .-(HA'), H, PtCl_s: yellow plates. — CaA', 2aq. — CaHA', 6aq: needles. — HO.CuA' 2aq: minute violet plates, insol. water. - AgA': crystalline pp.

Nitrile C₉H₈N.CN. [88°]. (above 360°). Formed as above and also from (B. 1)-amidoquinoline by diazotisation and treatment with CuCy₂ (Freydl, M. 8, 581). Crystals, sl. sol. Aq. Tetrahydride C₁₆H₁₁NO₂. [147°]. Formed

by reducing the acid with tin and HCl (Fischer by leading active with the late (Present a. Körner, B. 17, 765). Yields a crystalline nitrosamine C₁₀H₁₀N₂O₃. [186°]. ψ-Isomeride C₁₀H₁NO₃. [338°]. Perhaps

identical with the preceding. Formed by warm-

ing quinoline with m-amido-benzoic acid, nitrobenzene, glycerin, and H,SO, (Lellmann a. Alt, A. 237, 318). Got also by saponifying its nitrile which is formed by fusing sodium quinoline ψ-ana-sulphonate with KCy in a current of hot air (Lellmann, B. 20, 1449; 21, 397). Snowy powder. HA'HCl aq. H,A',H,PtCl,: needles.-ZnA'2.-AgA'.

Tetrahydride C10H11NO2. [147°]. by reducing the acid or bromo-quinoline carb-

oxylic acid with tin and HClAq.—HA'HCl aq.

Nitrile .C₉H₄N.Cy. [89°]. Needles (containing 1½aq), melting at 70°. Effloresces, and then contains and melts at 74.5°. —
B'₂H₂PtCl₈: needles.

Quinoline (B. 2)-carboxylic acid
CO₂H.C=CH.C.CH:CH
CH:CH.C-N:CH
CH:CH.C-N:CH

acid. [291°]. Formed by heating p-amidobenzoic acid with glycerin, p-nitro-benzoic acid, and H₂SO₄ (Schlösser a. Skraup, M. 2, 518). Formed also by heating its nitrile with HClAq at 140° (Fischer a. Wittmack, B. 17, 440). Thick prisms, sl. sol. hot water, g. sol. acids and alkalis.—HA'HCl.—(HA')₂H₂PtCl_g.—CaA'₂ 2aq. -AgA'.

Nitrile C, H, N2. [131°]. Formed by distilling potassium quinoline p-sulphonate (from sulphanilic acid) with KCy. Needles, forming a red solution in HClAq.

Quinoline (B. 3)-carboxylic acid

CH:CH.C.CH:CH Quinoline-m-carb-CO.H.C=CH.C-N:CH

oxylic acid. [248°].

Formation. -1. By oxidation of (B)-diquinolyl with CrO, and HOAc (O. Fischer a. Loo, B. 17, 1901; 19, 2473).—2. By oxidation of (B. 3)-methyl-quinoline (Skraup a. Brunner, M. 7, 142).-3. By heating the stannochloride of camido-phthalic acid with c-nitro-phthalic acid, glycerin, and H.SO. (Tortelli, G. 16, 367).

Properties.—Needles (from water).

Salts.—Cu(OH)A' aq.—AgA'.—HA'HCl aq: triclinic prisms.—H.A',H.,PtCl_s: orange prisms.

Quinoline (B. 4)-carboxylic acid CH:CH — C.CH:CH Ouinoline Quinoline-o-carboxylic CH:C(CO₂H).Ö—N:CH

acid. [187°].

Formation. -1. By heating o-amido-benzoic acid with o-nitro-benzoic acid, glycerin, and H₂SO₄ (Schlosser a. Skraup, M. 2, 518).—2. By Lelimann a. Reusch, B. 22, 1392).—2. By heating its nitrile with conc. HClAq at 150° (Lelimann a. Reusch, B. 22, 1392).—3. Together with the (B. 1)-isomeride, by heating quinoline (B. 1,4)-di-carboxylic acid (Skraup a. Brunner, M. 7, 153).

Properties.—Needles, m. sol. cold water and alcohol. FeSO, gives a purple colour in neutral solutions. — HA'HCl: yellowish prisms. — H₂A'₂HCl: golden prisms. — H₂A'₂H.QtCl₃: orange needles.—CaHA's: needles. - AgA': pp.

Methylo-iodide HA'MeI. Slender yellow needles (La Coste, B. 15, 196). Moist Ag₂O forms a solution of the hydroxide which reproduces HA' on evaporation.

Nitrile C₁₀H₈N₂. [84°]. Needles. Yields B'₂H₂PtCl₈, crystallising in orange needles.

Quinoline (Py. 1)-earboxylie acid

C₆H₄C(CO₂H):CH Cinchoninic acid. [254°]. Formation .- 1. By exidation of cinchenine.

cinchonidine. cinchotenine, cinchotenidine, cinchonitine, and cincholepidine (Weidel, A. 173, 84; M. 3, 79; Skraup, A. 201, 303; M. 2, 601; Forst a. Böhringer, B. 14, 436; Schnider-schnitsch, M. 10, 55).—2. By oxidation of (Py. 1)-methyl-quinoline (lepidine) (Hoogewerff a.

Van Dorp, R. T. C. 2, 11).

Preparation.—By boiling cinchonine with nitric acid of S.G. 1.3 (Königs, B. 12, 97; Claus,

B. 18, 362).

Properties.-Slender needles (containing aq) (Skraup) or triclinic crystals (containing 2aq) a:b:c = .746:1:.817; $a = 81^{\circ} 37'$; $\beta = 120^{\circ} 2'$ $\gamma = 86^{\circ} 37'$ (Muthmann a. Nef, B. 20, 637). By slow evaporation of an aqueous solution it is obtained in monoclinic forms (containing 2aq), $a:b:c = \cdot 276:1: \cdot 533; \beta = 98^{\circ} 3'$ (Ditscheiner, A. 173, 84; Claus, B. 20, 1604). V. sl. sol. water and alcohol, insol. ether. Yields quinoline on distillation with lime, and oxy-quinoline carboxylic acid on fusion with potash. On heating with conc. H2SO, it yields quinoline p-sulphonic acid (Georgiovitch, M. 8, 644). Sulphuric acid and P₂O₃ at 1.75° gives an (a)-sulphonic acid C_bH₂N(SO₃H)(CO₂H), which forms very bitter triclinic crystals (containing aq), nearly insol. tricinic crystals (containing aq), nearly insolcold water, giving the salts (NH₁)₂Λ" 2aq, CaA" 2½ aq, BaA" 3aq, PbA" aq, and CuA" aq. H₂SO₄ and P₂O₅ at 260° give a (β)-sulphonic acid C₁₆H₂NSO₅ crystallising in bitter needles (containing 2aq), m. sol. cold water, forming the salts (NH₁)HA" 2aq. BaA" aq, and PbA" 4aq (Weidel, M. 1, 845; 2, 565; Georgievitch, M. 8, 644).—KMnO₄ forms pyridine tricarboxylic acid.

Salts .- HA'HCl .- (HA') 2H2PtCla: triclinic prisms.—HA'HClICl 2aq (Dittmar, B. 18, 1618). —HA'HNO₃. — (HA')₂H₂SO₄: long prisms. — KA' ½aq. — CaA'₂ 1½aq: prisms (Weidel). —CaA'₂ (Skraup). —CuA'₂: dark-violet plates, sl. sol. hot water .- AgA': crystalline pp.

Dibromids C, H, NO, Br, [188°]. Long red needles, decomposed by boiling water (Claus, B. 18, 1307).

Di-iodide C₁₀H,NO_.I₂. [c. 242°]. Steelblue tables, nearly insol. cold water.

Ethyl ether EtA'. [13°]. Trimetric crystals, v. sl. sol. water, v. sol. ether, sl. sol. alcohol (Van der Kolf a. Van Leent, R. T. C. 8, 217).—EtA'HgCl. [153°]. Small needles.— (EtA')₂H₂PtCl_s. [204°]. Orange-yellow needles.

A mide $C_{10}H_{\rm w}N_{\rm s}O$. [181°]. Needles, v. e. sol. hot water. $-B'_{2}H_{2}PtCl_{\rm e}$. [250°-255°].

Benzylo-bromide C10H, NO2C, H, Br. [130°]. Silky needles, v. sol. water and alcohol, insol. ether. By heating the aqueous solution or by treatment with alkalis, it is converted, by loss of HBr, into the anhydride CO-O, which crystallises in dimetric tables (containing 3aq) [84°] and has a bitter taste. This anhydride is converted by alkalis into CaH, N(C,H,)CO2H [218°] (Claus a. Muchall, B. 18, 363, 1310).

Tetrahydride C10H11NO2. Formed from cinchonic acid, tin, and HClAq (Weidel, M. 2, 29; 3, 61). Yields a nitrosamine [137]. — B'HCl 1; aq: monoclinic crystals; a:b:c= ·932:1:1·942; $\beta = 90^{\circ}$ 41'. Heated with H₂SO, it gives disulpho-cinchonic acid and methylquinoline (cincholepidine). -B', H, PtCl.

Acetyl derivative of the Tetrahydride C₁₀H₁₀AoNO₂. [164°]. Trimetric crystals; a:b:c=848:1: 569. Sl. sol. cold water and al-

cohol.—CaA'₂ 2aq: minute needles.
Quinoline (Py. 2)-carboxylic acid
C₈H, CH: CO₂H.
[273°].

Formation .- 1. By heating acridinic acid at 125° (Graebe a. Caro, B. 13, 100). - 2. By oxidation of (Py. 2)-ethyl- (or methyl-) quinoline (Riedel, B. 16, 1609; Doebner a. Miller, B. 18, 1643).

Properties.—Slender needles, sol. alcohol, sl. sol. cold water. Dissolves in acids and alkalis. Oxidised by KMnO, to pyridine tricarboxylic

Salts .- HA'HCl: needles, v. sol. water .-Picrate: [216°]. -CuA'2. - AgA': small prisms. (HA'), H.PtCl.: orange needles.

Quinoline (Py. 3)-carboxylic acid

CH:CH Quinaldinic acid. [156°]. Formed from (Py. 3)-methyl-quinoline by oxidation with chromic acid mixture (Doebner a. Miller, B. 16, 2472). Got also by oxidation of (α)-diquinolyl (Weidel a. Strache, M. 7, 300). Needles (containing 2aq), v. sol. hot water, acids, and alkalis. —CuA'_2aq. —CaA'_2.—AgA': amorphous precipitate.—AgHA'_2HNO, aq: silky needles. — HA'HCl aq. — (HA')_2H_2PtCl, 2aq. — (HA')_4L_2Cr_O,: sparingly soluble red crystals.

Quinoline (B. 1,4)-di-earboxylic acid CH:C(CO₂H).C.CH:CH [270°]. Formed by $CH:C(CO_2H).C.N = CH$ heating amido-terephthalic acid with glycerin, H.SO., and o-nitro-phenol (Skraup a. Brunner, M. 7, 147). Long needles (containing 2aq), v. sl. sol. cold water. Salts.—HA'HCl 1 dq.—(HA').H.PtCl₈.—Cu₃A'₂(HO)₂ aq: bluish pp.
Quinoline (Py. 2,3)-dicarboxylic acid

 $C_0H_1 < CH:C.CO_2H$ $N=C.CO_2H$ Acridinic acid. Formed by oxidation of acridine with KMnO, (Graebe a. Caro, B. 13, 99). Long needles (containing 2aq), sl. sol. cold water, v. sol. alcohol. Does not combine with acids. Decomposed by heat into CO, and a mono-carboxylic acid [2750]

Quinoline (Py. 1,3)-dicarboxylic acid

C₀H, C(CO₂H): CH [246°]. Formed from (Py. 3)-styryl-cinchoninic acid by oxidation with alkaline KMnO, (Doebner a. Peters, B. 22, 3009). Needles, sl. sol. cold water and alcohol.—CuA" aq.—Ag₂A": white pp.

Quinoline (a) dicarboxylic acid C₀H₅N(CO₂H)₂. [270°]. Formed by saponifying its nitrile. Slender needles (containing aq), sl. sol. alcohol and ether.

Nitrile C,H,NCy2 [222°]. Formed by heating potassium quinoline (a)-disulphonate with KCy (La Coste a. Valeur, B. 20, 99). Needles (from alcohol), insol. Aq, v. sol. alkalis.

Quinoline (B. 2, Py. 3)-dicarboxylic acid CO₂H.C=CH.C.CH:CH [275°-280°]. ĊH:CH.Ö.N=C.CO,H

Formed by oxidation of benzylidene-quinoline (B. 2)-carboxylic acid (Von Miller, B. 23, 2261).

References.—Bromo-, Nitro-, and Oxx-QUINOLINE CARBOXYLIC ACIDS.

QUINOLINE (Py. 8).CARBOXYLIC ALDE-HYDE C,H,N.CHO. [71°]. Formed by oxida-

tion of (Py. 3)-quinolyl-acrylic acid with KMnO. (Miller a. Spady, B. 18, 3404; 19, 130). Monoclinic plates (from ligroïn), sl. sol. water. Reduces ammoniacal AgNO₃. Yields a phenylhydrazide C₁₈H₁₃N₂ [198°] crystallising in yellow plates.

QUINOLINE HYDRIDES.

Polymeride of quinoline dihydride C18H18N2. [162°]. Formed by reducing quinoline with zinc-dust and HOAc, zinc-dust and NH₃, zinc and HClAq, or alcohol and sodium-amalgam (Königs, B. 12, 101, 252; 14, 99; Wyschnegradsky, B. 12, 1481; Lellmann, B. 22, 1337). Amorphous powder. Its solution in conc. HClAq is ppd. by water and by NaOAc. Yields a nitrosamine.

Quinoline dihydride (?). (220°-226°). Found in small quantity among the products of the action of KOH on quinoline (O. de Coninck, C. R. 94, 87).—B'₂H₂PtCl₆.

Quinoline tetrahydride C.H., N i.e.

C₈H₄<CH₂,CH₂. [c. 10°]. (240° uncor.).

Formation.-1. By reduction of quinoline with zinc or tin and HClAq (Wyschnegradsky, Bl. [2] 34, 339; B. 12, 1481; 13, 2400), with zinc-dust and NH3Aq, with alcohol and sodiumamalgam (Königs, B. 14, 99; 16, 727), or with sodium (Weidel a. Glaser, M. 7, 328).—2. From carbostyril, alcohol, and Na (Knorr a. Klotz, B. 19, 3302).

Properties .- Needles, sol. water, volatile with steam. Secondary base. ICl forms in presence of HCl an amorphous pp. Colla LN (Dittmar, B.

18, 1619).

Reactions .- 1. The vapour passed through a red-hot tube yields indole and quinoline,—2. Chromic acid mixture yields quinoline.—3. Netro-benzene yields quinoline. p-Chloro-nitrobenzene at 200° does the same (Lellmann a. Reusch, B. 22, 1389).—4. HI and P reduce it to Lengfeld, B. 23, 1159).—5. Br forms cily CyH₁₀, and C₂H₂, and CyH₂, an chloride and NaOH form C,H,ON.SO.C,N, [67°], crystallising in plates, sl. sol. alcohol, water (Schotten a. Schlömann, B. 24, 3695) .-Methyl chloroformate gives C₀H₁₀N.CO₂Me [c. 35°], which may be oxidised by KMnO₄ in the cold to an acid [156°] and at 100° to a compound [175°] crystallising in red needles.-8. Diazobenzene chloride and aqueous NaOAc form $C_9H_{10}N.N_2C_9H_5$, which is split up by dilute H2SO4 into phenol and quinoline tetrahydride.-9. Potassium cyanate acting on the hydrochloride forms C₀H₁₀N.CO.NH₂ [150.5°], crystallising in needles, sl. sol. cold water. It is converted by conc. H₂SO₄ and HNO₃ at 0° into C₂H₈(NO₂)₂N.CO.NH₂ [191°], sl. sol. alcohol, and C₂H₃(NO₂)₂N [161°], v. sol. slochol, which forms a nitrosamine [127°] (Thomas, R. T. C. 10, 148).—10. Benzoic aldehyde and ZnCl₂ yield CHPh(C₉H₁₀N)₂ [153°], while p-nitro-benzoic aldehyde forms a corresponding body [177°] (Einhorn, B. 19, 1243).

Salts. - B'HCl. [181°]. — B',H,PtCl,. Prisms (from alcohol) or B'H₂SO₄. [137°]. tables (from water).

Acetyl derivative C.H. NAc. Yields CO.H.CO.NH.C.H.CO.H [1:2] on oxidation by KNnO.

Bensoyl derivative C.H., NBz. [750]. Tables (from alcohol). Oxidised by KMnO, to benzoyl-isatic acid (Schotten, B. 24, 772).

Nitrosamine C, H, N(NO). Oil. Converted by alcoholic HCl into the isomeric (B. 2)nitroso-quinoline tetrahydride [134°], which separates from benzene in steel-blue crystals, converted by NaNO₂ and HOAc into C,H₃N₂O₂ [98°] (Ziegler, B. 21, 864). Phenyl-hydrazine forms C_vH₁₀N₂O.PhN₂H₃ [120°]. Zinc-dust and HOAc reduce the nitrosamine to the hydrazine $C_0H_{10}N(NH_2)$ [56°] (c. 255°), which crystallises from ligroin, and forms B' H2SO, 2aq, crystallising in yellow plates. The hydrazine is oxidised in ethereal solution by ppd. IIgO to the tetrazone C18H20N4, which forms colourless needles [160°], sol. ether, sl. sol. alcohol.

Methylo-chloride v. Hydrochloride of

v-Methyl-ouinoling tetrahydride.

Ethylo-iodide B'Etl. Changed by alkalis into v-ethyl-quinoline tetrahydride, which is a liquid (254°-258°) yielding (C,H,0NEt), H.CdCl,, [105°], and (C,H,0NEt), H,PtCl, [c.460°) (Wyschnegradsky, B. 13, 2400; Claus a. Stegolitz, B. 17, 1329).

Quinoline tetrahydride C,H1,N. Formed by distilling cinchonine (1 pt.) with KOH (3 pts.) (O. de Coninck, C. R. 94, 87; A. Ch. [5] 21, 478). Got also by distilling brucine with potash (De Coninck, C. R. 99, 1077). Slightly hygroscopic oil, v. sol. acids. Reduces FcCl₃. May be oxidised to quinoline.—B'HCl: deliquescent needles, v. sol. water. - B', H, PtCl, -B'₂H₂PtCl₄: pale orange plates.

Quinoline hexahydride C,H13N. 720 mm. A product of the action of HI and P at 230° on the hydrochloride of quinoline tetrahydride (Bemberger a. Lengfeld, B. 23, 1155). Liquid, turning brown in air, m. sol. hot water. FeCl, gives a brown colour on warming. Diazo benzene sulphonic acid gives a light-red colouring matter. Phosphomolybdic acid gives a white pp. Potassio-mercuric iodide gives no pp. NaNO, in acid solution gives an oily pp. of the nitrosamine.—B'HCl. [170°]. Silky needles. B'HBr. Long silky needles.

Quinoline decahydride C,H,,N i.e.

CH₂·CH₂·CH.CH₂·CH₂·CH₂·CH₂·CH₂·CH₂·CH₂·CH₃·CH Formed by heating the hydrochloride of quinoline tetrahydride (3 pts.) with HI (16 pts. of S.G. 1.9) for 7 hours at 230° (Bamberger a. Lengfeld, B. 23, 1145). Needles or prisms (from ligroin). Smells like coniine. Fumes with HCl. Sublimes, in needles, in the cold. M. sol. water, v. sol. alcohol and ether, sl. sol. alkalis. Gives no colour with FeCl, or diazo salts. Reduces anmoniacal AgNO, in alcoholic solution. Phosphomolybdic acid gives a white flocculent pp. changing to needles. Potassio-mercuric icidida. iodide added to the acid solution gives scarlet crystals changing to black prisms on warming.

Reactions .- 1. Phenyl-cyanate forms, ethercal solution, C₉H₁₈N.CO.NHPh, crystallising in needles [148°].—2. Phenyl thiocarbimide in ether forms C,H16N.CS.NHPh, crystallising from chloroform in tables [134:5°].—3. An ethereal solution of CS₂ gives C₂H₁₈N.CS.SNH₂C₄H₁₆, crystallising in needles [120°], not decomposed by boiling alcohol, but converted by iodine into

(C.H., N)HI and S₂(OS.NC, H., 2), which crystallises in colourless needles [81°], sol. alcohol.
Salts.—B'HCl. [276°]. Small tables.—
B'HI. [253°]. Silky needles.—B'HAuCl,.
[96°]. Golden needles.—B',H,PtCl,. [207.5°].
Acetyl derivative C,H,gNAc. Oil.

Remacul derivative C.H., NBz. [44°].

Bensoyl derivative C. H₁₆NBz. [44°]. ISOQUINOLINE TETRAHYDRIDE C. H₁₁N. (232°). Formed by the action of tin and HCl upon isoquinoline (Hoogewerff a. Van Dorp, R. T. C. 5, 305). Liquid, smelling like isoquinoline, sl. sol. water. Absorbs CO, from the air. forming a crystalline carbonate. are forming a crystatine caronate. The aqueous solution reduces AgNO₃. Yields an oily nitrosamine.—B'HCl. [196°]. Tables, sol. alcohol. Not hygroscopic.—B'₂H₂SO₄: sol. alcohol.—B'₂H₂PtCl₂. [232°]. Reddish-yellow tables, decomposed by hot water.

QUINOLINE HYDROQUINONE v. DI-OXY-QUINOLINE.

QUINOLINE-IODOFORM Quinoline, Reaction 20.

QUINOLINE-QUINONE C.H.NO., i.e.

CH.CO.C.CH;CH CH.CO.C.N=CH. Formed by the action of cold chromic acid mixture on (B. 4,1)-oxy-amido-quinoline (Fischer a. Renouf, B. 17, 1644). Flat needles with green reflex (from alcohol), decomposing at 110°-120°. Its salts are decomposed by water. Reduced by sulphurous acid to dioxy-quinoline. Aniline in alcoholic solution forms, on boiling, the dianilide C₁₈H₁₀N₂O₂ crystallising from dilute alcohol in small copperred plates with green reflex [c. 190°], forming a

wiolet solution in HClAq.

Mono-oxim CH.C(NOH).C.CH:CH
CH.CO — C.N—CH

Formed by the action of NaNO2 and HClAq on (B. 4)-oxy-quinoline (Von Kostanecki, B. 24, 152). Needles (from alcohol). Gradually blackens below 220°, decomposing completely at 245°.

Di-oxim CH.C(NOH).C.CH:CH CH.C(NOH).C.N=CH. by adding hydroxylamine hydrochloride to an aqueous solution of the mono-oxim (Von Kostanecki a. Reicher, B. 24, 156). Minute crystals. Ac₂O yields a crystalline di-acetyl derivative de-composing below 160° with evolution of gas. Dyes cotton mordanted with iron salts greenishblack.

Quinoline-o-quinone C,H,NO... Formed by oxidising (B. 2) oxy-(B. 1 or 3)-amido-quinoline with FeCl, in acid solution (Matheus, B. 21, 1887). Unstable.—B'HCl: long reddish-yellow needles. Decomposed by Na₂CO₂, forming a brown solution. The sulphate forms yellow plates.

Mono-oxim C,H,N(OH)(NOH). from p-oxy-quinoline, NaNO2, and HCl (M.).

Golden needles (from HOAc), and HCi (M.). Golden needles (from HOAc), sl. sol. ether. Di-oxim C.H., N(NOH). Needles, decomposing at 190° (Von Kostanecki a. Reicher, B. 24, 158). Converted by cone. KOHAq into the anhydride C.H., N(N,O), which forms colourless needles, readily volatile with steam.

QUINOLINE (B. 1)-SULPHONIC ACID CH:0(80.H).C.OH:CH A product of the CH:CH --C.N=CH.sulphonation of quinoline (O. Fischer, B. 15, 6:3, 1979; 20, 731; La Coste a. Valeur, B. 20,

97). Formed also from amido-benzene m-sul phonic acid, nitrobenzene, glycerin, and H2SU at 160° (Lellmann a Lange, B. 20, 1446). Mono clinic needles (containing aq). Yields oxy-quino line [224°] by potash-fusion.—CaA'₂5aq: needles v. e. sol. water. According to Lellmann, there exists an isomeric quinoline (B. 1)-sulphonic acid, also got by sulphonation of quinoline, with H₂SO₄ (containing 50 p.c. SO₃ extra) at 260 (Lellmann, B. 20, 2172). This \(\psi\)-acid is converted by conc. H₂SO₄ at 250°-300° into the (B. 2)-acid (Lellmann, B. 22, 1391). The \(\psi\)-acid forms an hydrous crystals.

Tetrahydride C.H. N.SO.H aq. [315°] Formed by reducing the above acid (B. 4)-bromo quinoline (B. 1)-sulphonic acid and also (B. 4). oxy-quinoline (B. 1)-sulphonic acid with tin and HClAq (Lellmann a. Lange, B. 20, 3087; Claus, J. pr. [2] 42, 344). Trimetric crystals (from dilute solutions) or monoclinic crystals (from cone. solutions). FeCl_s gives a brown colour passing through purple to grass-green on warming.

Quinoline (B. 2)-sulphonic acid

SO,H.C=CH.C.CH:CH

CH:CH.C.N=CH. Formed by heating a mixture of amido-benzene-p-sulphonic acid, glycerin, nitrobenzene, and H₂SO₄ (Happ, B. 17, 191). Formed also (to the extent of 70 p.c.) by heating quinoline with conc. H2SO4 at 240°-300° and by heating the (B. 1)- or $(\beta 4)$ - acid with conc. H2SO at 240°-300° (Georgievitch, M. 8, 578, 639). Monoclinic needles (containing $1\frac{1}{2}aq$), sl. sol. alcohol and cold water. Not melted at 260°. Potash-fusion yields (B. 2)-oxy-quinoline [193°]. Bromine-water gives a yellow pp. of di-bromo-quinoline [126°] and at 100° Br (3 mols.) forms tri-bromo-quinoline [170°] (Claus a. Küttner, B. 19, 2884). Heating with KCy gives C.H.N.Cy [131°] which on saponification yields the carb.

oxylic acid [288°].
Salts. — KA' (dried at 120°). Tables. —
BaA'₂ (dried at 120°).—AgA': slender needles. —
Ag₂HA'₃: needles. — (HA')₁₈K₄I₉ 6aq: lustrous green crystals.

Ethyl ether EtA'2aq. Crystals, v. sol. water (Claus a. Happ, B. 18, 366).—EtA'KI; unstable brown needles, v. sol. water (Claus a. Stegelitz, B. 19, 921).—EtA'KBr.,—EtA'HgCl.,

Benzyl ether C,H,A'2aq. Monoclinic crystals.—C,H,A'KI, needles with blue reflex.

Quinoline (B. 3) sulphonic acid CH:CH.C.CH:CH SO₃H.O=CH.C.N=CH. [above 300°]. Formed by heating quinoline with H2SO4 (containing 15 p.c. SO, extra) at 130° (Claus, J. pr. [2] 37, 260). Small needles, v. e. sol. water, v. sol. alcohol. Potash-fusion yields oxy-quinoline [165°-200°]. Bromine forms di-bromo-quinoline [255°] and tri-bromo-quinoline [199°].—NaA'3aq. KA' 2aq. — CaA', 4aq. — BaA', 4aq. — PbA', CuA', 2aq: dark-green crystalline powder. Ethyl ether EtA'. [275°]. Needles (from

alcohol).

Chloride C.H.N.SO.Cl. Viscid mass. Amide C.H.N.SO.NH. [119°]. Crystalline. Quinoline (B. 4)-sulphonic acid :CH ____ C.CH:CH CH:CH -Quinolins o-sulphonic CH:C(SO,H).C.N=CH acid. Formed, together with a smaller quantity of the p- acid, by heating quinoline with fuming

H.SO, at 170° (O. Fischer a. Bedall, B. 15, 683, 1979; 20, 731; Riemerschmied, B. 16, 721; La. Coste a. Valeur, B. 20, 95; Claus, B. 19, 925, 2882; J. pr. [2] 37, 260). Formed also by heating quinoline with conc. H,SO, at 220° (Georgievitch, M. 8, 641). Monoclinic prisms, v. sl. sol. water. Oxidised by KMnO, to pyridine dicarboxylic (quinolinic) acid (Fischer, B. 17,755) and a small quantity of (1.9.3) and the small quantity of (1.9.3) and (1.9 a small quantity of (1,2,3)-sulpho-amido-benzoic acid (Zürcher, B. 21, 180). Changed by conc. H₂SO₄ at 250° to the (B. 2)-isomeride (Georgievitch, M. 8, 578). Bromine-water forms a yellow insoluble pp. and, at 100°, tri-bromoquinoline [198°].

Salts.—NaA' 5aq (Spies, J. pr. [2] 37, 265). -KA' 2aq. -CaA', 9aq. Monoclinic crystals. PbA', -CuA', 2aq: small green needles.

Ethyl ether EtA'. [66°]. Needles (from chloroform). Decomposed by boiling water.

Chloride C.H., NSO, Cl. [124]. Needles. Amide C.H., N.SO, NH., [184]. Needles Amide C,H,N.SO,NH, (from water) (Hoogewerff a. van Dorp, R. T. C. 8, 184). Converted by Br and KOHAq into C.H.NSO.NBrK 2aq, crystallising in yellow needles, m. sol. water, and converted by HOAc into C,H,NSO,NBrH, crystallising from acctone in needles, yielding (CoH.NSO2NBr)2Ba 2aq.

Quinoline (a)-disulphonic acid $C_9H_b(SO_3H)_2N$. Formed, together with the (β)someride, by heating quinoline (B. 4)-sulphonic acid with fuming H.SO, at 250° (La Coste a. Valeur, B. 19, 995; 20, 98). Yellow needles (containing 3aq), v. sol. water, insol. alcohol.-K₂A"3½aq: satiny plates, v. e. sol. water.—BaA"3aq. S. 4.08 at 15°.

Quinoline (β) -disulphonic acid

C₀H₃N(SO₃H)₂. Formed as above (La Coste a. Valeur, B. 19, 998; 20, 3199). Needles (containing 1 aq), v. sol. water, insol. alcohol .-KA" aq : crusts, sl. sol. cold water .- BaA" 2aq : white powder, sl. sol. cold water (difference from (a) - isomeride).

References. - Bromo- and Oxy-QUINOLINE SULPHONIC ACIDS.

ISOQUINOLINE SULPHONIC ACID

C₂H₂N(SO₂H). Formed by heating isoquinoline (1 pt.) with fuming H₂SO₄ (2 pts.) at 100° (Hoogewerff a. van Dorp. R. T. C. 5, 305).—

BaA', 9aq. Needles, v. sol. water.
QUINOLINIC ACID v. Pyridine Dicarri-OXYLIC ACID. The name is also given by Dewar (Pr. 30, 164) to an acid C₉H₉NO₃ [143°] formed in small quantity in the oxidation of quinoline (derived from cinchonine) by boiling aqueous KMnO. (a)-DIQUINOLYL O₁₈H₁₂N₂ i.e.

 $C_{o}H_{\bullet} < CH:CH:CH:CH:CH > C_{o}H_{\bullet}$ Diquinoline.

[176°]. (above 400°). V.D. 8·73 (calc. 8·86). Formation.—1. By heating quinoline with sodium at 192° (Weidel, M. 2, 491; 7, 327).—2. In small quantity (8 p.c.) by passing dry oxygen into a mixture of quinoline and quinoline hydrochloride in presence of platinum-black (Weidel,

M. 8, 120).

Properties. — Monoclinic plates, a:b:c=1.37:1:1.32; $\beta=109^{\circ}58'$. Insol. water, sol. alcohol, ether, and benzene. Oxidised by KMnO. and HOAc to cyclothraustic (C, H, N,O,), quinoline (Py. 8)-carboxylic, oxyisocinchomeronic (oxy-pyridine dicarboxylic), and o-amido-benzoic

acids (Weidel a. Strache, M. 7, 280, 806; 8, Alkaline KMnO, forms isocinchomeronic, o-amido-benzoio, and pyridanthrillic (C₁₅H₁₆N₃O₄) acid. MeOH and H₃SO₄ form B''MeSO₄H (Ostermayer, B. 18, 333, 597).

Salts.—B''H₂Cl₄ 4aq; white needles.—

B"H,PtCl, aq.—B"HAuCl, 2aq.—B"H,SO, aq. Methylo-chloride B"Me,Cl, 6aq: needles.

B'Me,Cl,2ICl. [238°]. Lemon-yellow pp.

Methylo-iodide B''Mel. [283°].

Ethylo-iodide B''Etl. Yellow needles

(from water), sl. sol. water (Roser, B. 17, 2769).

Sulphonic acid C₁₈H₁₁N₂(SO₂H). Formed by heating diquinolyl with H₂SO₄ (containing 5 p.c. SO₃ extra) (Weidel a. Glüser, M. 7, 308). Minute needles, almost insol. hot water, sol. conc. HClAq and H.SO4. Converted by potashcone. richa and H₂SO₄. Converted by potasniusion into oxy-diquinolyl [208°].—KA'2aq: needles, v. e. sol. water.—Cuh'₂2aq.

(a)-Disulphonic acid C₁₈H₁₀(SO₂H)₂N₂.

Formed by heating diquinolyl (10 pts.) with

H₂SO₄ (11 pts.) and SO₃ (34 pts.) at 170° (Weidel, M. 2, 503). Minute needles, sl. sol. water. Yields, by potash-fusion, di-oxy-di-quinolyl [239°].—K₂A" 5aq: needles.—CuA" 6aq: bluish-green crystals, nearly insol. water.

(β)-Disulphonic acid C18H10(SO3H)2N2 Formed, together with the mono-sulphonic acid, by heating (a)-diquinolyl (100 pts.) with H2SO (332 pts.) and SO, (18 pts.) for 20 hours at 190° (Weidel a. Glüser, M. 7, 322). Small needles, converted by potash-fusion into di-oxy-di-quinolyl [above 305°].—K.A" (dried at 120°): crystalline powder.—CuA" (dried at 120°).

(β)-Diquinolyl

CH:CH.C.CH:C.CH:CH CH:N—C.CH:C.CH:N—C₆H, [192°].

Formation .- 1. By heating quinoline with BzCl at 250° (Japp a. Graham, C. J. 39, 174) .-2. In very small quantity by distilling cinchoninic acid with lime (Weidel, M. 2, 501). -3. By passing quinoline through a red-hot tube (Zimmermann a. Müller, B. 17, 1965).-4. By distilling quinoline (B. 4)-sulphonic acid; the yield being 10 p.c. (O. Fischer a. Loo, B. 17, 1899; 19,

Properties .- Iridescent plates (by sublimation) or colourless prisms (from ether), sol. hot benzene, alcohol, and ether, insol. water. Weak base, the salts being decomposed by water. pase, the saits being decomposed by water. Oxidised by CrO₃ and HOAc to quincline (B. 3)-carboxylic acid. CrO₃ and H₂SO₄ give pyridyl-quincline carboxylic acid C₂H₃N.C.H₃N.CO₂H [273°]. Bromine forms C₁₈H₁₂N₂Br₁ [192°].

Salts.—B"H₂SO₄: sparingly soluble concentric needles.—B"H₂PtCl₆: granular pp.

Ethylo-iodide B"Etl. Very unstable

red crystals, decomposed by hot water.

C18H10(SO3H)2N2. Disulphonic acidFormed by heating the base (1 pt.) with conc. H₂SO₄ (10 pts.) at 180°. V. e. sol. water.— K2A" Baq: prisms.

(γ).Diquinolyl CH:N—C.CH:CH-CH-CH.C.N -CH CH:CH.C.CH:C—C=CH.C.CH:CH Di-p-

quinolyl. [178°].

Formation.—1. By boiling a mixture of benzidine, nitrobenzene, glycerin, and H,SO. (Roser, B. 17, 1817, 2767; O. W. Fischer, M. 5, 418; Colson, C. R. 108, 677). A better yield is got by using o-or p-nitrophenol instead of nitrobenzene (Ostermaver a. Henrichsen, B. 17, 2444). When crude benzidine is used there is also formed a base C_{2.}H₁₈N₂O₃, which yields B'2SnCl₂ [135°] and B''H_{2.}PtCl₂ 2aq (Colson, C. R. 107, 1003; 108, 677).—2. By heating azobenzene with glycerin and H₂SO₄ (Claus a. Stegelitz, B. 17, 2380).

Properties .- Monoclinic crystals, insol. water, sl. sol. ether, v. sol. hot alcohol and benzene. MeOH and H₂SO₄ at 180° form B"(MeHSO₄)₂2aq, crystallising in needles. Bromine in alcohol forms unstable $C_{18}H_{12}N_{.0}Br_{.2}$ and $C_{13}H_{12}N_{.2}Br_{.4}$, converted by HClAq at 190° into C18H11BrN2 [150°-

155°7.

Salts. - B"H2Cl2 4aq: white needles. B"HAuCl, 2aq: slender needles.—B"H, SnCl,: colourless needles. - B"H_PtCl₆ (dried at 105°) B"H₂Cl₂2ICl: cheesy pp. (Dittmar, B. 18, 1618).

-B"H₂SO₄3aq. -B'2H₂SO₄. -B"2H₂Cr₂O₇. -B"C₀H₃(NO₂),OH: minute yellow prisms.

Methylo-iodides B"MeI. Cryst

Crystals. B"Me₂I₂. [c. 300°]. Yellow needles, sol. water. Ethylo-iodide B"2Etl. [270°]. Needles.

Disulphonic acid C₁₈H₁₀(SO₃H)₂N₂. White powder, insol. water and alcohol.—
Na₂A" 5aq: small needles. The same, or an isomeric, disulphonic acid is got by heating benzidine disulphonic acid with o-nitro-phenol, glycerin, and \dot{H}_2SO_4 . It crystallises in plates or needles, and yields \dot{K}_2A'' aq.

(8)-Diquinolyl

CH:N-C.CH:CH CH.CH:CH.C.CH:CH

CH:CH.C.CH:C C.N=CH'
[148°]. Formed by heating o. p-di-amido-diphenyl hydrochloride with nitrobenzene, glycerin, and H2SO, (O. W. Fischer, M. 6, 546). Leaflets, insol. water, sol. hot alcohol and benzene. Bromine in presence of water forms orange bromne in presence or water forms orange needles of C₁₈H₁₂N₂Br₁.—B"H₂Cl₂: needles, v. c. sol. water.—B"H₂PtCl₆ aq: reddish-yellow crystalline pp.—Picrate. [168°]. Yellow needles.

Methylo-iodide B"MeI. [126°]. Needles.

Disulphonic acid C₁₈H₁₀(SO₂H)₂N₂. Four-sided tables, not melted at 300°. Si. sol. hot water. - BaA" 3aq: needles, m. sol. hot water.

(Py. 3, B. 1 or 3)-Diquinolyl $C_{18}H_{12}N_2$. [159°]. Formed (7 pts.), together with the isomeride [115°], by heating a mixture of m-amido-(Py. 3)phenyl-quinoline (20 pts.), glycerin (70 pts.), o-nitro-phenol (15 pts.), and H₂SO₄ (60 pts.) (Miller a. Kinkelin, B. 18, 1910). Small monoclinic tables, sl. sol. ether, cold alcohol, and chloroform.—B"H₂Cl₂2aq: plate's.—B"H₂PtCl₃ $-B''H_2SO_4$: easily soluble needles. $-B''C_6H_3N_3O_7$.

-B'H₂SO₁: easily solution needles. -B'U_eH₂N₂O₁. [240°]. Crystalline powder.

Methylo-iodide B''MeI. [263°]. Needles. (Py. 8, B. 3 or 1)-Diquinolyl C₁₈H₂N₂. [115°]. Formed as above (M. a. K.). Lightyellow triclinic crystals, v. sol. alcohol, ether, and benzene, sl. sol. ligroin. -B''H₂Cl₂3aq: tables, v. e. sol. water .- B"H2PtCla: crystalline.

--C.N=CH \cdot Formed from p-amido-(Py. 3)-phenyl-quinoline, glycerin, nitro-benzene, and H₂SO₄ (Weidel, M. 8, 140). It is also a product of the action of oxygen on a mixture of quinoline hydrochloride, aniline, and platinised asbestos at 180°. Monoelinic tables (from alcohol).—B"H,PtCl,: crystalline powder. B"HCl: yellow. B"H,Cl.

Methylo-iodide B"MeI aq. [232°]. Small needles (from water), sl. sol, boiling water.

Sulphonic acid C₁₈H₁₁(SO₃H)N₂. Insoluble powder. Potash-fusion yields an oxy-

diquinolyl [187°].

diquinolyl [187].

(B., Py. 1)-Diquinolyl C₁₈H₁₂N₂. [122°]. Got by heating (a)-amido-(Py. 1)-phenyl-quinoline [150°] with glycerin, nitro-benzene, and H₂SO₄ (Koenigs a. Nef, B. 20, 632). Large crystals (from benzene). May be distilled. V. e. sol. alcohol, v. sl. sol. ether. Strong base.—
B"H₂PtCl₃: granules, sol. cone. HIAq.

(B., Py. 1)-Diquinolyl $C_{18}H_{12}N_2$. [117°]. Got by heating (β) -amido-(Py. 1)-phenylquinoline [198°] with glycerin, nitro-benzene, and H.SO, (Koenigs a. Nef, B. 20, 634). Tables (from benzene), v. e. sol. alcohol. May be distilled. Strong base. — B'H,PtCl_e: ye needles.—Picrate. [248°]. Bulky flakes. yellow

(Py. 2,3)-Diquinolyl

 C_eH_i CH:C—C=N C_eH_i . [176°]. Formed by the action of (Py. 3)-quinolyl-acetic aldehyde on o-amido-benzoic aldehyde in alcoholic solution (Carlier a. Einhorn, B. 23, 2895).

Plates (rom alcohol).—Aurochloride: [248°].
—Platinochloride: [278°].—B"H₂Cl₂ 4aq.

Methylo-iodide B"MeI.

Diquinolyl tetrahydride C18H16N2. [118°]. Formed by heating (Py. 3)-chloro-quinoline with quinoline tetrahydride (Friedländer a. Weinberg, B. 18, 1533). Crystals, sl. sol. ligroin, insol. water. May be distilled. HClAq forms a deep-yellow solution.

Reference. - OXYDIQUINOLYL.

(Py. 3) QUINOLYL-ACETIC ACID

C₆H₄CH:CII N=C.CH₂CO₂H. [275°]. Formed from the aldehyde by potash-fusion or by oxidation Carlier a. Einhorn, B. 23, 2896). Formed also by oxidation of a-oxy-quinolyl-propionic acid with KMnO₄. Needles (from alcohol).—Hydrochloride: [243°]; needles. — Silver salt: white scales, yielding quinaldine on distilling with lime.

(Py. 3)-QUINOLYL-ACETIC ALDEHYDE C₁₁H_pNO i.e. C₂H₅N.CH₂.CHO. [104°]. Formed by careful oxidation of α-oxy-quinolyl-propionic acid (Einhorn, B. 18, 3467; 19, 908). Crystals (from alcohol). Yields a phenyl-hydrazide [199°].—B'₂H₂PtCl₆2aq.—B'C₆H₃N₃O₇. [212°].

QUINOLYL-ACETONE v. ACETONYL-QUINOL-

(Py. 3)-QUINOLYL-ACETYLENE

C.H.N.C:CH. Formed by distilling a solution of di-bromo-quinolyl-propionic acid with Na, CO, (Carlier a. Einhorn, B. 23, 2896). Volatile oil. Br forms C.H.N.CBr:CHBr.

(Py. 3)-QUINOLYL-ACRYLIC ACID

C₁₂H₂NO₂ i.e. C₈H₄ < CH: OH N=C.CH: CH.CO₂H. [193°]. Formed by the action of boiling potassium carbonate solution upon 'quinolyl-acrylo-trichloride' C.H.N.CH:CH.CCl, aq [145°], which is got by heating (Py. 3)-methyl-quinoline with chloral at 110° (Miller a. Spady, B. 18, 3402, 3465; 19, 130; Einhorn, B. 19, 908). Plates. Oxidised by KMnO, to aldehydo-quinoline. HBr forms acid. - *BaA',: β-bromo-quinolyl-propionic needles, sl. sol. cold water. - *HA'HOl: needles.

OWINGLYL-ACRYLO-TRICHLORIDE

TRI-(B. 2)-QUINOLYL-CARBINOL

(C.H. N), C.OH. [108°]. Formed by oxidising tri-quinolyl-methane with H, CrO, and HOAc (Noelting a. Schwarz, B. 24, 1608). Needles, v. sol. alcohol, sl. sol. ligroïn.

(B. 3, Py. 8)-QUINOLYLENE DIACRYLIC CH:CH.C.CH:CH

ACID

CO,H.CH:CH.C=CH.C.N=C.CH:CH.CO,H. [over 300°]. Formed by boiling tri-chloro-propenyl-quinolyl-acrylic acid with K₂CO₃Aq (Éckhardt, B. 22, 284). Sol. acids and alkalis. Insol.

water, sl. sol. hot alcohol.

DI-(B. 2)-QUINOLYL-ETHANE C₂₀H₁₀N₂i.c. C₃H₆N.OH₂·Ch₂N. [124°]. Formed by heating di-p-amido-di-phenyl-ethane with nitrophonol, glycerin, and H₂SO₄ (Comey, B. 23, 1115). Hexagonal plates, insol. water, sl. sol. ether.—B"H_Cl, 4aq: needles, v. sol. water.—B"H_Cl, - B"H_PtCl, - B"H_PtCl, - B"HAUCl, - Sulphate: prisms, m. sol. cold water.

(Py. 3)-QUINOLYL-ETHYLENE C,1H,N i.e.

 $C_{e}H_{\bullet} < CH:CH > N = C.CH:CH$. Formed by boiling β bromo-quinolyl-propionic acid with ono. K.CO₃Aq (Einhorn, A. 246, 172). Oil. — B'₂H, PtCl₃ 4aq. [187°].—B'HAuCl₄. [159°]. (B. 3, P₂y. 3). Di-quinolyl-ethylene C₆H₁, N₂

Formed by heating m-amido-(Py. 3)-styrylquinoline with o-nitro-phenol, glycerin, and H₂SO₄ (Wartmann, B. 23, 3650). Oil, v. sol. alcohol, sl. sol. ether.

Methylo-iodide B'MeI 13aq. Golden needles v. sol. hot water and alcohol.

Yields C₂₀H₁₁N₂Br₂McI. [210°]

QUINOLYL-DI-ETHYL-PHENOL C10H10NO i.e. C. H. N.C. H. Et. OH. This is probably the constitution of apocinchene (Comstock a. Königs,

B. 20, 2674; \hat{v} . vol. ii. p. 174).

(B. 4)-QUINOLYL-HYDRAZINE $C_0H_0N_3$ i.c.

CH:N-C ____C.N₂H³ [64°]. Formed from (B. 4)-amido-quinoline by diazotisation and treatment with SnCl₂ and HCl (Dufton, C. J. 59, 757; Böttinger, B. 24, 3277). Needler (from ether) or prisms (from ligroin). — B"H₂Cl₂: prisms. Converted by potassium cyanate and HCl into C₂H₈N.NII.NH.CO.NH₂ [235°], and by pyruvic acid into C,H,N.N,H:CMc.CO,H crystallising in orange needles, converted by boiling HClAq into quinindole (a)-carboxylic acid

HClAq into quinindole (a)-carboxylic actu $C_{12}H_{10}N_{.}O_{.2}$ [286°].

(B. 1)-Quinolyl-hydrazine [151°]. Formed in like manner from ana-amido-quinoline (Dufton, C. J. 61, 785). Yellow needles (from water). Yields B'HCl [248°] and is converted by cyanic acid into $C_{1}H_{2}NH.NH.CO.NH_{2}$ [255°], the horseign addition of the N. NH.NH.CO.NH 2005 and the horseign addition of the NH.NH.NH.CO.NH 2005 and the horseign addition of the NH.NH.NH.CO.NH 2005 and the horseign additional to the NH.NH.NH.CO.NH 2005 and the horseign and the NH.NH.CO.NH 2005 and the horseign and the by benzoic aldehyde into C.H.N.NH.N:CHPh [194°], by acetone into C.H.N.NH.N:CMc. [140°] and by pyruvic acid into the acid C.H.N.NH.N:CMc.CO.H [185°], whence boiling HClAq forms the corresponding quinindole carboxylic acid, which decomposes at about 300°.

DIQUINOLYLINE is DIQUINOLYL.

DI.(B. 2)-QUINOLYL KETONE (C.H.N)2CO. [174°]. Formed from di-p-amido-benzophenone, glycerin, H₂SO₄, and pieric acid (Noelting a. Schwarz, B. 24, 1608). Needles, v. sol. alcohol,

gl. sol. hot water. - B"H,Cl. [over 200°]. Needles, v. e. sol. water and alcohol

(Py. 3)-QUINOLYL-MERCAPTAN

CeH. CH: CH [174°]. Formed by heating (Py. 3)-oxy-quinoline with P.S. at 145° (Roos, B. 21, 620). Yellow plates, sl. sol. hot water, v. sol. hot alcohol. Yellow dye. Combines with acids and bases. Does not react with hydroxylamine or phenyl-hydrazine.

Ethyl derivative C.H.N.SEt. Formed from quinolyl-mercaptan, NaOEt, and Etl. Oil, decomposed by distillation .- B'HI. [154°] .-

B',II,PtCl, aq. [c. 190°]. Octahedra. TRI-(B. 2)-QUINOLYL-METHANE

CH(C,H,N), [202°]. Formed from p-rosaniline, glycerin, H,SO,, and pieric acid at 150° (Noelting a. Schwarz, B. 24, 1606). Needles (containing EtOH), melting at 98°. Melts at 202° when anhydrous. — B"'3HCl: plates, sol. water. — B"C₄H₃N₃O₇: yellow needles.—B", H₁₂Pt₃Cl₂₁: yellow crystals.—B""3MeI. [266°].

(B. 2)-QUINOLYL-METHENYL-AMIDOXIM

C(NOH)(NII.).C=CH.C.CH:CII CH:CH.C.N=CH. [105°]. Formed from CoH. N.Cy, hydroxylamine hydrochloride, Na₂CO₃, and dilute alcohol (Biedermann, B. 22, 2761). Yellowish needles, m. sol. hot water. Fehling's solution gives a greyish-green pp. FeCl, gives a deep-red colour. AgNO, gives a white pp. yielding a mirror.

Reactions .- 1. Phthalic anhydride on warming forms $C_9H_6N.C < N.O > C.C_6H_1.CO_2H$ [203°].

2. Ac_O yields $C_{_{0}}\mathrm{H_{_{6}}N.C} { <\!\!\!\! < \!\!\! < \!\!\!\! \stackrel{N.O}{\sim} \!\!\!\! > \!\!\!\! \mathrm{CMe}}$ [175°], crystallising in needles. - 3. The hydrochloride is converted by potassium evanate into $C_0H_1N.C(NOH).NII.CO.NH_2$ [165°]. 4. Chloroformic ether forms $C_0H_0N.C(NII).NO.CO.Et$ [97°], which is converted by NaOIIAq into $C_{\nu}H_{e}N.C \stackrel{N.O}{<_{NH}} > 0$ [155°].

Salts .- B'HCl: needles .- B'2H2PtCle. Acetyl derivative C.H.N.C(NOAc).NH [115°]. Formed by means of AcCl in the cold. Needles, insol. cold water, sl. sol. ether.

Ethyl ether CgH6N.C(NOEt).NH2. Formed from the amidoxim, NaOEt, and Etl. Needles, v. sol. alcohol and hot water.

(Py. 3)-QUINOLYL-PROPIONIC ACID
C_yH_nN.CH_y.CH_y.CO_yH. [116°]. Formed by reducing quinolyl-acrylic acid with sodiumamalgam (Cartier a. Einhorn, B. 23, 2896). Ethyl ether Eth'. [116°]. Needles.

Reference. -- OXY-QUINOLYL-PROPIONIC ACID.

DI-(Py. 3)-QUINOLYL DISULPHIDE [137°]. Formed by oxidising (C,H,N),Š,. quinolyl-mercaptan with H.O. in dilute alcohol (Roos, B. 21, 622). Plates (from alcohol), insol. water and alkalis.

QUINONE C.H.O. i.e. CH.CO.CH. Benzoquinone. Mol. w. 108. [116°]. V.D. (H = 1) 53.4 (calc. 54) (Hofmann, 7. 3, 583). H.C. 659,020. H.F. 45,200 (from diamond) (Berthelot a. Recoura, Bl. [2] 48, 699; A. Ch. [6] 13, 312, 335; C. R. 104, 1572).

Formation.—1. By oxidation of quinic acid with MnO₂ (4 pt.), H₂SO₄ (1 pt.), and water (1 pt.) (Woskresensky, A. 27, 268).—2. By

oxidation of hydroquinone (Wöhler, A. 51, 148).

8. By oxidation of benzidine, of aniline, and of p-phenylene-diamine by MnO₂ and H₂SO₄ (Hofmann, Pr. 18, 4).—4. By action of MnO₂ and H₂SO₄ on amido-benzene p-sulphonic acid and on phenol p-sulphonic acid (Schrader, B. 8, 759).

Preparation.—1. By adding conc. Na₂Cr₂O, Aq to a cold solution of aniline (1 pt.) in H₂SO₁ (8 pts.) and water (25 pts.), and extracting with ether (Nietzki, B. 19, 1467).—2. 20 g. of aniline are dissolved in 600 c.c. of water containing 160 g. of H₂SO₁; 20 g. of finely-powdered potassium bichromate are added by degrees, with constant agitation, keeping the temperature at 10°-15°. After standing over night 33 g. more potassium bichromate are added; the quinone is then extracted with ether, dried over CaCl₂, and the ether removed by distillation. The yield is about 86 p.c. of the theoretical amount (Schniter, B. 20, 2283; cf. Seyda, B. 16, 687; Nietzki, B. 11, 1102; A. 215, 127).—3. From p-amidophenol. p-Amido-phenol sulphate is dissolved in water, some H₂SO₄ added, and then PbO₂ gradually, wich shaking, till the violet colour first formed disappears. The quinone is extracted with ether. Yield theoretical (Schmitt a. Siepermann, J. vr. (2110, 317)

Siepermann, J. pr. [2] 19, 317).

Properties.—Yellow monoclinic prisms (from water) or plates (from EtI) (Hesse, A. 114, 299), or needles (by sublimation). Its odour is characteristic. V. sl. sol. cold water, m. sol. alcohol and ether. The solutions turn the skin brown. Sol. HClAq and cone. HNO₃. Its alkaline solution turns brown in air (Laurent, C. R. 26, 35). An alcoholic solution of hydrocerulignone deposits, even in dilute solutions, crystals of cerulignone with steel-blue reflex.

Reactions .- 1. Chlorine forms tri - chloroquinone.—2. HCl and KClO3 give tetra-chloroquinone (Hofmann, A. 52, 55).—3. Conc. HClAq forms chloro-hydroquinone (Wöhler; Städeler, A. 69, 308) .- 4. HIAq forms quinhydrone and hydroquinone.—5. HBr passed into a solution in chloroform ppts. quinhydrone, and finally forms brome-hydroquinone. HBrAq forms, on heating di-bromo-hydroquinone (Sarauw, A. 209, 99). 6. Bromine. (1 mol.) in CHCl, is instantly absorbed. Excess of bromine (2 mols.) appears to form C.H.Br.O2, which is split up by heat into HBr and two di-bromo-quinones C.H.Br.O. [2:5:4:1] and [2:6:4:1] (Nef, J. pr. [2] 42, 167).— 7. HNO, on heating yields oxalic and picric acids and HCy (Nietzki, A. 215, 138, —8. Ammonia gas forms emerald-green quinonimide C.H.NO, sol. water, the solution soon turning black (Woskresensky). NH, in presence of chloroform produces hydroquinone, quinhydrone, and brown C.H.NO. (Zincke, B. 16, 1556).—9. An alcoholic solution exposed to sunlight yields hydroquinone and aldehyde (Ciamician, G. 16, 111). - 10. Hydrasine hydrate gives hydroquinone and a compound $O_2H_4(OH)_2N_2H_4$ (Curtius a. Thun, J. pr. [2] 44, 191).—11. Heated in a sealed tube alone at 160°, or with water at 100°, it yields hydroquinone and quinhydrone (Scheid, A. 218, 227).-12. PCl, forms a thick oily product, C₁₂H₂O₄P₃Cl₈. Water acting upon this forms C₁₂H,O₄P₂Cl₈. Water acting upon this forms mono- and di-chloro-hydroquinone.—13. Heated with POCl, quinone gives mono- and di-chlorohydroquinone. An amorphous body C₂₁H₁₄O₁₁

is also formed.—14. Alcoholic H.S form C, H, SO, a yellowish crystalline mass, melting below 100°.-15. AcCl forms in the cold the di-acetyl derivatives of chloro-hydroquinone. On warming it also forms CeH2Cl2(OAc)2 (Schulz, B. 15, 652). AcBr, in like manner, gives $C_0H_0Br(OA0)_2$ and $C_0H_0Br_2(OAc)_2$ —16. Ac_O does not act below 200°, when it forms $C_0H_4(OAc)_2$ and a brown mass. 17. Cold dilute NaOAc converts it into hydroquinone (Hesse, A. 220, 365).—18. Aniline in boiling alcoholic solution forms di-phenyl-di-amidoquinone and hydroquinone 3C,H,O2+2NH2Ph quinone and hydroquinone $3U_0H_1U_2 + 2NH_2I^*n = O_0H_2(NHPh)_2O_2 + 2C_0H_1(OH)_2$. Other primary and secondary bases act in like manner.—19. o- and p- Nitro-aniline form red crystals $C_0H_1O_2C_0H_1(NO_2).NH_2$ melting at 97° and 120° respectively (Hobebrand, B. 15, 1976). o-Nitro-aniline in HOAc forms $C_0H_2O_2(NH.C_0H_1NO_2)$. [1:4:2:5] [305°] crystallising from alcohol in red needles (Leicester, B. 23, 2794).-20. o-Amidophenol in hot alcohol forms a base (C₂H₁₈N₁O₁?) which crystallises in violet needles [250°], al. sol. alcohol (Zincke a. Hebebrand, A. 226, 61). In alcohol (Zincke a. Hebebrand, A. 226, 61). In dilute acids it forms a red solution. Ac₂O yields $C_2, H_{16}Ac_2N, O_4$ [285°], while Bz_2O at 150° gives C_2, H_3Bz_2N, O_4 [265°]. Yields a crystalline nitrosoamine $C_2, H_{16}(NO)_2N, O_4$. Forms the salts $B''H_2Cl_2$, crystallising in needles with green lustre, $B''H_2SO_4$, $B''H_2PCl_3$, and a picrate crystallising in steel-blue needles [236°].—21. $C_9H_4(NH_2)(OMe)$ [1:2] forms $C_{20}H_{19}N_2O_4$ or $C_9H_2O_2(NH_2O_4)$. Ome) 2 crystallising in reddishviolet needles [230°], forming a blue solution in H_2SO_4 .—22. p-Amido-phenol hydrochlorids gives H2SO, -22. p-Amido-phenol hydrochloride gives C_bH₂O₂(NH,C_bH₄,OH)₂ crystallising in violet-brown needles, not melted at 290°.—23. (1,3,2). brown needles, not metica at 290°.—25. (1, 5, 2)Anido-o-cresol forms a compound [285°], which
gives a crystalline acetyl-derivative.—24. (2, 4, 1)Nitro-toluidine forms C₆H₄O₂,NH.C,H₆NO₂, decomposing at 300°, and C₆H₂O₂(NH.C,H₆NO₂),
(L.).—25. Acetoacetic ether and ZnCl₂ at 100° form C₁₆H₁₆O₆ [184°], crystallising in needles, insol. water, sol. hot alcohol. Conc. H₂SO₄ forms a deep-blue solution. Alcoholic potash forms $C_{14}H_{10}K_{2}O_{8}$ 2aq, the salt of an insoluble acid $C_{14}H_{12}O_{8}$ (Von Pechmann, B. 21, 3005). — 26. $C_{9}H_{4}(OH)(OMe)$ [1:4] in hot ligroin forms di-methyl-quinhydrone C₂₀H₂₀O₆, crystallising in lustrous greenish-black prisms, decomposed by warm water (Hesse, A. 200, 253).

Mono-oxim CO CH:CH C:N.OH or C(OH) CH.CH C NO no Nitrogo physical

C(OH) CH.CH C.NO. p-Nitroso-phenol. Mol. w. 123.

Formation.—1. By boiling nitroso-di-methylaniline (or nitroso-di-phenyl-aniline) hydrochloride with dilute NaOHAq (Baeyer a. Caro, B. 7, 809, 967; Ter Meer, B. 8, 622; Fischer, B. 19, 2995).—2. By adding KNO2 and HOAo to an aqueous solution of phenol (B. a. C.; cf. Stenhouse a. Groves, A. 188, 360).—8. By adding hydroxylamine hydrochloride to a cold dilute aqueous solution of quinone (Goldschmidt, B. 17, 213).—4. Formed also from aqueous phenol, hydroxylamine hydrochloride and H.O. (Wurster, B. 20, 2631). Free hydroxylamine merely reduces quinone to hydroquinone.

Properties.—Nearly colourless needles or greenish trimetric plates; a:b:a=:598:1:2-469.

M. sol. water, forming a light-green solution

which turns brown on boiling. V. sol. ether, acetone, and aqueous alkalis, sl. sol. HOAc. Decomposes at 120°-130°. Decomposed by hot Decomposes at 120-130. Decomposed by allowood. HClAq. When dissolved in phenol it gives, on addition of H,SO,, a cherry-red solution turned blue on addition of KOHAq. In this reaction the compound C, H, NO, is formed. Polyhydric phenols, containing two hydroxyls in the m-position, give by like treatment fluorescent 'dichroïns'; thus resorcin gives $C_{18}H_{15}NO_8$, $C_{36}H_{28}N_2O_{19}$, and azoresorcin (Brunner a. Chuit, B. 21, 249).

Reactions.-1. Oxidised by alkaline K, FeCy, to p-nitro-phenol.—2. Reduced by tin and HClAq to p-amido-phenol.—3. Nitrous acid gas passed into an ethereal solution forms diazophenol nitrate (Jaeger, B. 8, 894).—4. Gaseous HCl passed into a cooled ethereal solution forms HCl passed into a cooled ethereal solution forms di-chloro-amido-phenol [175°] and tri-chloro-amido-phenol (J.; Hirsch, B. 13, 1908).—5. A solution of HCl in McOH in presence of ice forms C₂H₂Cl₂(NH₂)(OMe) [72°]; while EtOH and HCl give C₂H₂Cl₂(NH₂)(OEt) [46°] (275°). 6. Conc. KOHAq at 180° forms azophenol C₁₂H₁₆N₂O₂ [214°] (Jaeger).—7. KClO₃ and HClAq form C₆H₄ClNO₂, crystallising in yellow needles, v. sol. alcohol, insol. water, and explading at 70° (Möhlen R. 19 281).—8. ploding at 70° (Möhlau, B. 19, 281).—8. ClO Me added to its sodium salt forms C₀H₁(NO).O.CO₂Me [137°], while ClCO₂Et yields C₀H₁(NO).O.CO₂Et [109°] (Walker, B. 17, 400). 9. BzCl added to the sodium salt in ether forms C.H.(NO).OBz, crystallising in yellowish needles [168°-175°], sol. hot alcohol (Walker).—10. Aniline forms azophenine C₆H₂(NPh)₂(NHPh)₂, p-Chloro-aniline forms, in like manner, tetra-chloro-azophenine [205°] (Fischer a. Hepp. B. 21, 677) .- 11. Bromine forms C, H2Br2O(NOH), crystallising in small leaflets, decomposed by water (O. Fischer, B. 21, 674).-12. Phenyl cyanate gives C.H.O.NO.CO.NHPh, crystallising in short yellow prisms decomposed at 160° without melting. It is converted by alkalis into the oxim, aniline, and CO, (Goldschmidt a. Strauss, B. 22, 3105).

Salts.-C.H.(NO)(ONa) 2aq. Red needles (from alcohol), v. sol. water, insol. ether. Decomposed by boiling water. Ppd. by NaOH from aqueous solution.—(C₈H₄(NO).O) Ba (dried at 100°). Red needles (from warm water).— -C_sH₄(NO).OAg aq. Violet crystals with green reflex.

Dioxim C(NOH) CH:CH C(NOH). Formed

by the action of hydroxylamine hydrochloride on the mono-oxim, on hydroquinone, and on pnitroso-aniline (Nietzki, B. 20, 613; 21, 430; Fischer, B. 21, 685). Yellowish needles (from hot water). Decomposes at 240°. Reduced by SnCl, and HCl to p-phenylene-diamine. Oxidised by alkaline K.FeCy, into insoluble di-nitroso-benzene. Ac.O forms a crystalline di-acetyl derivative, sol. hot alcohol.

C,H,<NCI Quinone-chlorimide [85°].

l'ormed by the action of bleaching powder on a solution of the hydrochloride of p-amido-phenol (R. Schmitt, J. pr. [2] 8, 1; 19, 816; Hirsch, B. 11, 1980; 13, 1903; Fogh, B. 21, 890; Andresen, J. pr. [2] 23, 167) or C.H.(NH₂).OEt. Purified by steam-distillation. Golden crystals (from HOAc). Sl. sol. cold water, v. sol. alcohol and ether. Explodes above 86°. Smells like quinone. Stains the skin brown. Turned brown by alkalis. Reduced by tin and HCl to p-amidophenol. Water at 100° forms quinone. Aqueous 80, forms amido-phenol sulphonic acid. HCl gives chlorinated amido-phenols. Gives Liebermann's colour reaction with phenol and H₂SO₄.
Quinone-di-chlorimide C₆H₄N₂Cl₂ i.e.

C₅H₄ NCI. Formed from p-phenylene-diamine hydrochloride and bleaching-powder solution (Krause, B. 12, 47). Needles (from water), decomposing at 124°. Almost insol. cold water. Its solution stains the skin brown. Reduced by SnCl₂ to p-phenylene-diamine. HCl forms tetrachloro-p-phenylene-diamine. Br gives di-chlorodi-bromo quinone. (β)-Naphthylamine forms C_{1s}H_{1s}N_sO, which dyes silk crimson and yields B'HNO₃ (Nietzki a. Otto, B. 21, 1745).

Quinone-phenylimide C₁₂H₁₁NO i.e.

 $C_6H_4<\stackrel{\mathrm{NPh}}{\circ}$ [97°]. Formed by oxidising p-oxydi-phenyl-amine in benzene by HgO (Ban-drowski, M. 9, 134, 415). Red crystals, v. sol. alcohol, ether, and chloroform. Decomposed by water and alkalis. Acids reproduce quinone. Reacts with aniline, forming p-oxy-di-phenylamine and di-phenyl-di-amide-quinone-phenyl-

Quinone-p-tolylimide C, H, NO. Formed in like manner from p-oxy-phenyl-ptolyl-amine (B.). Dark-red scales (from ligroin), sol, most solvents. Di-methyl-amido-phenylimide C14H14N2O i.e.

C.H. C.H. NMe. Phenol-blue. Formed by the action of nitroso-di-methyl-aniline on an alkaline solution of phenol, or by exidation of a mixture of phenol and phenylene-di-methyl-p-diamine (Möhlau, B. 16, 2851; 18, 2913). Formed also from quinone-chlorimide and di-methylaniline (Fogh, B. 21, 889). Steel-blue prisms (from water) (containing aq). Its solution in HClAq is blue. Conc. H.SO, forms quinone and $C_eH_4(NH_2)(NMe_2)$. Boiling NaOHAq forms NMe₂H and C_eH_4 . O. The sulphonio acid C₁₄H₁₄N₂SO₄ ½aq, formed from *p*-amidophenol-sulphonic acid in water by successive treatment with Cl and dimethylaniline, crystallises in bronzed needles, forming a blue solution in NaOHAq.

NaOHAq. Quinone tetrahydride $CO < CH_{r}CH_{2} > CO$. Diketohexamethylene. [78°]. Formed by heating the dihydride of di-oxy-terephthalic acid (succinyl-succinic acid) of 200° and distilling the product under reduced pressure (Hermann, A. 211, 322; Baeyer a. Noyes, B. 22, 2170). Prisms, v. sol. water. FeCl, does not colour its solution. Its alkaline solution turns brown in the air. Bromine forms C₆Br₁O₂. Reduces Fehling's solution. HCy forms C₆H₈(OH)₂Cy₂ [180°]. Yields a di-oxim which when quickly heated melts at 200°; when slowly heated at 192°. The di-phenyl-di-hydrazide C.H.(N2HPh)2 is obtained as a white pp. [125°] crystallising from alcohol in yellow prisms [150°], yielding a crystal-line hydrochloride B"H.Cl.

An isomeride of the tetrahydride CaHaOs, [1707], is got by the action of NaOHAq on succinyl-succinic ether. It crystallises in prisms (containing laq). It changes into the preceding isomeride on distillation. It reduces Fehling's solution.

Oxy-amido-, and Oxy-quinone.
TRIQUINONE v. BENZENE-TRI-QUINONE.

QUINONE DICARBOXYLIC ACID dihydride v. DI-OXY-TEREPHTHALIC ACID.

Tetrahydride v. Dihydride of DI-OXY-TEREPHTHALIC ACID.

Quinone tetracarboxylic acid. Methylether C₂O₂(CO₂Me)₄. [207°]. Formed by oxidation of C₂(OH)₂(CO₂Me)₄ with HNO₃ (Nef. A. 258, 318). Colourless prisms (containing 2MeOH) (from MeOH) or yellow needles (by sublimation).

Ethyl ether CoO2(CO2Et)4. Formed by oxidising di-amido-pyromellitic ether with conc. HNO₃ (Nef. C. 3:53, 428; A. 237, 28). Golden needles (from alcohol). May be sublimed. On treatment with KOHAq or with H₂SO₄ in HOAc it yields hydroquinone tetra-carboxylic ether. Zinc-dust and HOAc also reduce it to hydroquinone tetracarboxylic ether.

QUINOPHENOL v. OXY-QUINOLINE.

$C_{\mathfrak{s}}H_{\mathfrak{s}} < N > C_{\mathfrak{s}}O_{\mathfrak{s}}.$ DIQUINO-PHENAZINE

Formed by the action of dilute HNO, on CeH.: N2:C6O2(OH)2, which is got from rhodizonic acid and o-phenylene-diamine (Nietzki a. Schmidt, B. 21, 1228). Yellowish needles (containing 3aq), sl. sol. water. Converted by o-phenylene-diamine sulphate crystallising in greenish needles. into C21H12N6,

DIQUINOQUINONE CH/CO.CO\CH. Di-CO.CO

The di-oxim CoH2O2(NOH)2 is diquinoyl. nitrosoresorcin (q.v.) (Goldschmidt a. Strauss, B. 20, 1611; Kehrmann a. Messinger, B. 23, 2816). The dioxim is converted by hydroxylamine into the tetra-oxim, which, on heating amine into the tetra-oxim, which, with Ac₂O, yields the anhydride $C_eH_2N_4O_2$ crystalliaing in needles [61°], sol. ether. The tetraoxim may be reduced by SnCl, and HCl to tetraamido-benzene.

Triquinoquinone v. Benzene TRIQUINONE. Reference. - OXY-DIQUINOYL.

$C_6H_3Me < N > C_6O_4$ DIQUINO-TOLAZINE

Formed from rhodizonic acid and tolylene-odiamine, the product being oxidised by HNO, (Nietzki a. Kehrmann, B. 20, 324). Yellow needles (containing 2aq). On warming with an aqueous solution of a salt of tolylene-o-diamine it is converted into C2, H18O6, which crystallises from chloroform in needles (containing CHCl3).

QUINOVATANNIC ACID C14H18O8? Occurs in the bark of Cinchona nova (Quina nova) (Hlasiwetz, A. 79, 129). Translucent yellow mass, sol. water and alcohol, insol. ether. FeCl₂ gives a dark-green colour. NH₃Aq colours its solution brown. Its alkaline solution absorbs oxygen from the air. Boiling dilute H_2SO_4 splits it up into sugar and 'quinova red' $C_{28}H_{28}O_{12}$ (Rembold, A. 143, 273), which also occurs in the bark. Quinova red is a nearly black resin, nearly insol. water, v. sol alcohol, ether, and alkalis,

gives no colour with FeCl, and yields protocatechuic acid on fusion with potash.

QUINOVIN $C_{10}H_{16}O_{8}$ (Hlasiwetz) or $C_{28}H_{44}O_{11}$ (Oudemans, jun., R. T. C. 2, 160). Quinovabitter. Quinovic acid. $[a]_{b}=+59^{\circ}$. Occurr in false einchona bark from Cinchona nova (Pelletier a. Caventou, J. Ph. 7, 112; Winckler, Rep. Pharm. 51, 193; Buchner, jun., A. 17, 161; Peterson, A. 17, 165; Schnedermann, A. 45, 277; Rochleder a. Hlasiwetz, A. 79, 129; 111, 182). Occurs also in true cinchona bark (Schwarz. A. 80, 330; De Vrij, J. Ph. [3] 37, 255), in all parts of Cinchona Calisaya (from Java), and in

tormentilla root (Rembold, A. 145, 9).

Preparation.—The bark is extracted with boiling milk of lime, the extract ppd. by HCl and the pp. repeatedly dissolved in alcohol

and thrown down by water.

Properties.—Needles (from alcohol), almost insol. hot water, v. sl. sol. ether, v. sol. dilute alcohol. Tastes bitter. Dextrorotatory. Sol. aqueous alkalis. Resolved by acids into quinovic acid and quinovite. Does not reduce Fehling's solution.

Salts.—PbC₃₀H₄₀O₈aq.—(CuO)₃4C₃₀H₄₈O₈. (β)-Quinovin. [c. 235°]. [α]_D = + 28° in a 2·7 p.c. alcoholic solution. Occurs in cuprea bark (from Remijia) (Liebermann a. Gicsel, B. 16, 928). Scales (from dilute alcohol). Insol. ether, v. é. sol. alcohol. Dextrorotatory. Forms with alcohol the compound $C_{as}H_{s2}O_{11}5EtOH$, crystallising in large prisms. Split up by dilute acids into quinovic acid and quinovite.

Quinovite $C_0H_{12}O_4$ i.e. $C_0H_{3}O(OH)_3$. Quinovasugar. (c. 300°). $[a]_0=60^\circ$ (O.); $=+78^\circ$ (I. a. G.). Formed by the action of HCl on a hot alcoholic solution of quinovin; quinovic acid crystallises out, and the mother-liquor is neutralised by BaCO, filtered, and evaporated. Hygroscopic mass, sol. ether. Has a bitterswect taste. Does not ferment with yeast. Reduces Fehling's solution.

Tri-acetyl derivative C,H,O(OAc), [47°]. (c. 303°). White needles (Liebermann,

B. 17, 872).

Quinovic acid C.H.O. (Oudemans, R. T. C. 2, 160); $C_2H_{38}O_1$ (Hasiwetz a. Gilm, A. 111, 182); $C_2H_{38}O_2$ (Liebermann). $[\alpha]_D = +86^{\circ}$. Occurs in tormentilla root (Rembold, A. 145, 6). Formed from quinovin as above. White sandy powder composed of minute trimetric six-sided lamine, insol. water, v. sol. hot alcohol, sl. sol. ether. Tasteless. Ppd. from alkaline solutions by acids in a gelatinous form, gradually becoming pulverulent. Dextrorotatory. H2SO gives off CO and forms novic acid, quinochromin gives to CO and forms now sent, quinterform $C_{30}H_{44}O_2$ (crystallising in needles), quintervene $C_{32}H_{12}(?)$, and apoquinovic acid $C_{14}H_{26}O_4$ (crystallising in needles; whence $C_{16}H_{22}NaO_4$ $3^1_2_3aq$). Salts.—K_C2, $H_{30}O_1$ $1^1_2_3aq$; bulky pp.— $CuA''Ou_3(OH)_6$ 5aq: light-blue pp.— Ag_2A'' :

bulky pp.

Ethyl ether C32H16Et2O6. [127°-130°]. rystals, v. sol. alcohol and ether.

Pyroquinovic acid C₃₁H₃₈O₄. (above 360°). Formed by heating quinovic acid (Liebermann a. Giesel, B. 16, 936). Needles, insol. water, v. sol. alcohol and ether. Its alkaline solution is lævorotatory. On distillation, the distillate solidifies to a clear glassy mass, easily soluble in ether, and resembling gum copal in its proper-

ties. When this substance is heated with HI and P it yields a terpene (quinoterpene) which probably has the formula C_{so}H_{4s}. This terpene is also formed by direct reduction of pyroquinovic acid with HI and P (Liebermann, B. 17,

869).
Salts.—KA' (dried at 110°).—BaA'₂.
Quinoterpene C₃₀H₄₈. (above 360°). Formed

as above. Dextrorotatory.

Oxy-quinoterpene C₉H₁₈O₂ or C₂₈H₃₄O.

Cholestol. [139°]. (above 300°). Accompanies quinovin in false cinchona bark (Liebermann, B. 17, 871; 18, 1803; Hesse, A. 234, 377). Needles (from alcohol). Reduced by HI and P to quinoterpene. Yields an acetyl derivative [126°] and a benzoyl derivative [144°].

QUINOXALINE C.H., N. i.e. C.H., N.CH.

[27°]. (222° uncor.). Formed by the action of o-phenylene-diamine on glyoxal in aqueous solution (Hinsberg, B. 17, 320; A. 237, 334). White crystals, smelling like quinoline and piperidine, miscible with cold water, alcohol, ether, and benzene. Partially separated from aqueous solution by warming or by adding KOHAq. Its aqueous solution gives white pps. with HgCl, and AgNO,. Yields a sparingly soluble oxalate. Little attacked by oxidising agents. Sodium reduces it, in alcoholic solution, to phenylene-ethylene-diamine (Merz a. Ris, B. 20, 1190).- B'HCl: needles, v. sol. water. Decomposes at 184°.—B'H₂SO₄. [187°]. Silvery plates, v. sol. water.—B'₂H₂PtCl₆ (dried at 100°). Needles.

References .- ANIDO- and OXY-QUINOXALINE.

RACEMIC ACID v. TARTARIC ACID. RACEMIC CAMPHOR v. CAMPHOR.

RADICLE. Lavoisier and his followers regarded an acid as a substance formed by the combination of much oxygen with another body; the body with which the oxygen was combined was called by de Morvoau the radicle of the acid, and the name was used in this sense by Lavoisier. 'Il faut donc distinguer dans tout acide la base acidifiable, à laquelle M. de Morveau a donné le nom de radical, et le principe acidifiant, c'est-à-dire, l'oxigène' (Traité élé-mentuire de Chimie [1789] 1, 69). That the radicle of an acid might be either a simple or a compound substance is evident from de Morveau's use of the term; in speaking of the nomenclature of acids of unknown composition, he says: 'Nous nous sommes contentés de désigner l'être simple qui y modifie l'oxigère par l'expression de base acidifiable, ou, pour abréger, de radicle, de têt acide ' (Mémoire sur le Développement des Principes de la Nomenclature Methodique [1787]). Lavoisier, in 1780, extended the meaning of the term radicle when he said (Traité, 1, 209) that most of the oxidisable and acidifiable radicles of mineral compounds were simple bodies, whereas the radicles of compounds of vegetable and animal origin were generally composed of at least two simple bodies. The notion of radicles was here, and elsewhere, extended by Lavoisier to mean the bases or foundations whereon more complicated bodies were built up, generally by the addition of oxygen.

As organic chemistry advanced, and many compounds were obtained from animal and vegetable sources, attempts were naturally made to find some reason for the existence of so vast a number of compounds all composed of but three or four elements. Lavoisier's assertion that the radicles of organic compounds are themselves composed of two or more elements, was revived, adopted, and developed. Berzelius, Liebig, Dumas, and other earlier workers in organic chemistry were struck by the enormous number of compounds produced by the union

of the four elements carbon, hydrogen, oxygen, and nitrogen. They said the true elements of organic chemistry are the radicles cyanogen, amidogen, benzoyl, cthyl, &c., &c. Dumas (C. R. 5, 300) said: 'In mineral chemistry the radicles are simple, in organic chemistry they are compound; therein consists the whole difference. The laws whereby the compounds are formed and their reactions are regulated are the same in both.' Liebig said: 'Organic chemistry is the chemistry of compound radicles.' In 1832 Liebig and Wöhler made apparent the meaning and wide applicability of the dictum that organic chemistry is the chemistry of compound radicles' by their researches into the constitution of the compounds obtained from oil of bitter almonds. By regarding these bodies as compounds of the radicle benzoyl, C,H,O, they became comparable with the compounds of the radicles potassium and other metals. From this time the conception of the radicle was firmly established.

The elements are the simple radicles, on which, and by the combinations of which, compounds are built up. The reactions of a series of compounds often show such similarities that we are obliged to conclude that the compositions of these compounds are also similar; in many cases this similarity of composition can be made apparent only by supposing that a certain group, or collocation, of elements enters into the composition of all the compounds. Such a group of elements, playing the part of a simple body throughout a series of reactions, but nevertheless separable into two or more elements, is

called a compound radicle.

For an example of the working out of the conception of the radicle v. AMMONIUM COM-DOUNDS, vol. i. pp. 200-201. M. M. P. M.

RADI OIL. The product of the distillation of the wood of a juniper. Contains a sesquiterpene Cl. H₂₁, whose hydrochloride C₁₂H₂₁2HCl melts at 118° (Wallach, A. 238, 82).

RAFFINOSE C₁₂H₂₂O₁₆5aq (Morris a. Brown, C. J. 53, 619; De Vries, R. T. C. 8, 326; C. R.

106, 751; Tollens a. Mayer, B. 21, 1569). Melitose. Gossypose. Melitriose. Mol. w. 528 to 644 (by Raoult's method) (cal. 594); 596 (by rate of osmosis in leaves of Tradescantia). [c. 87°]. S. 17 at 16° (R.); 14 at 20° (Loiseau). S. (80 p.c. alcohol) 1.4 at 70°. [α]_D = 104.6 (M. a. B.). [α]_J = 116.6. H.O. 2,019,700 (Stohmann, J. pr. [2] [4]_D = 104.6. [2]_D = 104.6. [2]_D = 10 45, 320; cf. Berthelot a. Matignon, C. R. 111, 13). Discovered by Johnston (C. S. Mem. 1, 159) in a manna, which drops from various kinds of eucalyptus in Tasmania. Further examined by Berthelot (C. R. 41, 392) and Rischbiet a. Tollens (B. 18, 2611). Occurs also in cotton-seed (Ritthausen, J. pr. [2] 29, 351; Böhm, J. pr. [2] 30, 37), in beet-root molasses (Loiseau, Bl. [2] 26, 365; Tollens, B. 18, 26; A. 232, 201; Lipmann, B. 18, 3087; Lindet, G. B. 110, 705; Blanck, G. 18, 3087; Lindet, C. R. 110, 795; Bl. [3] 3, 682).

Preparation .- Cotton-seed cake is extracted with spirit (S.G. 848). The extract is boiled down to a small bulk, and then shaken with ether (to remove colouring matters). After a time lumps of sugar separate; these are dissolved in 80 p.c. alcohol at 70°, boiled with animal charcoal, and allowed to stand. In a week glittering needles, arranged in hemispherical masses, separate (H. Ritthausen, J. pr. [2]

29, 351).

Properties .- Groups of needles, v. c. sol. hot water, v. sl. sol. alcohol. Has a slightly sweet taste. Does not reduce Fehling's solution. Not turned brown by boiling KOHAq. At 108° it gives off its water of crystallisation without melting; the anhydrous raffinose is not very hygroscopic. A second hydrate (containing 6aq) may be got as lamellee by crystallisation from dilute alcohol (Berthelot, C. R. 109, 548; Bl. [3] 2, 656). Readily ferments, giving with good yeast approximately as much alcohol as cane-sugar, while with feeble yeast only onethird of that quantity is formed. Raffinose can be assimilated by young plants, being converted into starch (Brown a. Morris, C. J. 57, 486).

Reactions.—1. Boiling dilute H.SO, splits it into levulose and 'melibiose' C. H. O. I. which yields with phenyl-hydrazine the osazone $C_{21}H_{22}N_1Q_0$. The mixture of lævulose and melibiose shows $[a]_D=50^\circ$. On further boiling with dilute H2SO, the melibiose is hydrolysed, the product consisting of galactose (1 mol.), lawulose (1 mol.), and dextrose (1 mol.) (Scheibler a. Mittelmeier, B. 22, 1678, 3118; Tollens, A. 238, 508; 249, 227). Melibiose is identical with eucalyn, and may be reduced by sodiumamalgam to melibiotite C12H21O11, a syrup which does not reduce Fehling's solution, but yields galactose on boiling with dilute acids. Invertin also splits up rasilnose first into lævulose (which may be fermented by yeast) and melibiose, and then this melibiose may be split up at 36° by a conc. solution of invertin into dextrose and galactose. The Pneumococcus of Friedländer sets up fermentation in suitable solutions of raffinose (Percy Frankland, C. J. 59, 270). 2. NaOEt gives a compound containing 6 to 7 p.c. sodium.—8. Boiling HNO₃ (S.G. 1·15) gives 23 p.c. of mucic acid. Saccharic acid is also formed.

Salts (Beythien a. Tollens, A. 255, 195) .-

 $\begin{array}{l} -C_{18}H_{28}U_{16}BaO.-C_{18}H_{22}O_{16}2BaO.\\ C_{18}H_{22}O_{16}(CaO)_3 2aq.-C_{18}H_{22}O_{16}8PbO. \end{array}$

Estimation. - In a mixture of cane-sugar and raffinose, the amount of raffinose may be determined by observing the change of rotatory power after hydrolysis (Creydt, B. 19, 3115; Gunning, Fr. 28, 45). The raffinose may also be ppd. by lead acetate from a solution in methyl alcohol, and the effect on the polarising action of the liquid observed (Lotman, Chem. Zeit. 12, 391; Gunning)

RANGIFORMIC ACID C₁₁H₁₈O₂. [106°]. Occurs, together with atranoric acid, in the lichen Cladonia rangiformis (Paterno, G. 12, BANGIFORMIC ACID C11H18O1. 259). Plates (from benzene), sol. other. Its ammoniacal solution gives a flocculent pp. of

AgA' on adding AgNO₃.

RAPIC ACID C18H34O3. Occurs as glyceride, together with the glycerides of erucic and behenic acids, in rape-seed oil (Reimer a. Will, B. 20, 2387). Oil. Yields stearic acid on fusion with potash. The zinc salt melts at 78°. The Na salt is gelatinous, v. sol. water, sl. sol. alcohol.

REDUCINE C₁₂H₁₂N₂O₃ or C₆H₁₁N₃O₄. An alkaloid occurring, as well as para-reducine C₆H₂N₃O, according to Thudichum (C. R. 106, 1803) in urine. It reduces ferric, cupric, mer-curic, and silver salts, and forms an insoluble barium compound.

REDUCTION. This term is used as synonymous with deoxidation in its widest sense. v. DEOXIDATION, vol. ii. p. 377; and cf. OXIDA-

TION, vol. iii. p. 657. REGIANIN v. JUGLONE.

RENNET v. MILK and PROTEÏDS. RESACETIC ACID v. vol. i. p. 18.

RESACETOPHENONE v. DI-OXY-ACETO-

PHENONE.

RESINS. Amorphous substances, occurring in all parts of plants, but especially in the bark (Wiesner, Sitz. W. 52 [2] 118). Frequently associated with essential oils. Resins are also formed from various oils by atmospheric oxidation or by the action of alcoholic potash. Boiling aqueous potash resinifies aldehydes. P.O. converts various aldehydes (e.g. benzoic aldehyde) into resins. These resins are solid, translucent, with conchoidal fracture, insol. water, wholly or partially sol. alcohol and aqueous alkalis. The resins, therefore, contain acids. The resins soften when heated, but are decomposed by distillation. By potash-fusion protocatechnic acid is obtained from guaiacum, benzoïn, dragon's blood, asafœtida, esparto resin, myrrh, acaroid resin, and opopanax. By potash-fusion p-oxy-benzoic acid is got from benzoïn, dragon's blood, aloes, and acaroid resin; phloroglucin from dragon's blood, esparto resin. and gamboge; and resorcin from galbanum, asafætida, gum ammoniac, sagapenum, and acaroid resin (Hlasiwetz a. Barth, A. 134, 265; 138, 61; 139, 83). Dammar, sandarac, mastic, and incense-resin are not attacked by fused potash. Resins containing gum or mucilage, soluble in water, are called gum-resins. Resins mixed with essential oils are termed balsams. The following resins are completely soluble in alcohol of 95 p.c. : benzoïn, caranna, resins and balsams from conifers (colophony), dragon's blood, guaiacum, mani-resin, mastic from Alexandria and from Bombay, black balsam of Peru,

podocarpus resin, sandarac, balsam of Tolu, anthorrhea resin. The following resins are only partially dissolved by alcohol of 95 p.c.; ammoniac, asafœtida, bdellium, Canada balsam, ceradia resin, copaiba balsam, copal, dammar, elemi, euphorbium, euryops resin, galbanum, gamboge, liquidambar, common mastic, Mecca balsam, myrrh, olibanum, opopanax, white balsam of Peru, sagapenum, sonora-lac, and liquid storax (Hirschsohn, Ar. Ph. [3] 10, 481; 11, 54, 152, 247, 312, 434). Ether dissolves completely: caranna, Canada balsam, conifer resins, copaiba balsam, dragon's blood, elemi, guaiac-resin, mani-resin, mastic, podocarpus resin, and sandarac. Most other resins are partially soluble in ether. FeCl, gives in alcoholic solution a blue colour with guaiacum and caranna, a dark-green colour with benzoin and some sorts of asafeetida, and a black colour with gamboge, balsam of Peru, opopanax, storax, sagapenum, shellac, and xanthorrhœa resin. FeCl, gives in an alcoholic solution of Canada balsam and of some sorts of dammar, a pp. which disappears on heating, and with copal and sonora-lac a pp. which does not disappear on heating. Alcohol containing HCl is coloured brick-red by white balsam of Peru and ceradiaresin; red to violet by common myrrh and euryops-resin; blue to violet by some sorts of elemi; yellowish-brown to green by guaiacresin; yellow, changing through brown to cherryred, by benzoin and balsam of Tolu; crimson by xanthorrhoa resin; greenish, changing to dingy violet, by asafœtida; yellow by gamboge and caranna; light rose-coloured by podocarpus resin; and brown by other resins. Conc. H., SO. forms a cherry-red solution with benzoin from Siam and with balsam of Tolu; a yellow solution with gamboge; a solution with yellowishbrown fluorescence with asafeetida; and brown with other resins. A drop of H,SO, added to a solution of pine-wood resin in HOAc gives a red or violet colour as the liquids mix (Morawski, C. C. 1888, 1630). Fossil resins (e.g. amber) are often found in beds of coal and lignite, being clearly derived from plants. Schmidt a. Erban (M. 7, 655; cf. Kremel, Fr. 26, 262) have determined, for a great variety of commercial resins, the quantity of alkali necessary to neutralise an alcoholic solution, and the amount required for saponification, and also the amount of iodine the resins can take up. They also base a method of separation upon the relative solubilities of resins. A classification of red resins according to their solubility in chloroform, benzene, and CS₂ is given by Dobbie a. Henderson (Tr. E. 30, 624). Colophony softens under boiling water, while powdered shellac, mastic, elemi, and dammar agglomerate, and sandarac, copal, and amber remain unchanged (Kliebhau, C. C. 1888, 87). The products of distillation of colophony have been examined by many chemists (Fremy, A. Ch. [2] 59, 13; A. 15, 284; Pelletier a. Walter, A. Ch. [2] 67, 267; Thénard, Robiquet, a. Dumas, C. R. 1838, i. 460; Schiel, A. 115, 96; Couerbe, J. pr. 18, 165; Curie, C. N. 30, 189; Kelbe, B. 13, 1157; B. 14, 1240; A. 210, 1; B. 15, 808; Renard, C. R. 91, 416; B. 18, 2000; Bl. [2] 36, 215; Tilden, B. 13, 1604; Anderson, C. N. 20, 76; Mills, 'Destructive Distillation,' 31; Tichborne, Ph. [8] i. 302; Morris, C. J. 41,

167) by whom the following substances have been described as constituents: water, reti-Taghthou as constituents: water, real-maphtha C,H_a (108°) (P. a. W.), retinyl C,H_a (150°) (P. a. W.), retinol C,H_a (150°) (286°-246°) (P. a. W.), retisterene [67°] (325°) (T. R. a. D.), (P. a. W.), retisterene [67°] (325°) (T. R. a. D.), carbonic acid, carbonic oxide, ethylene (S.), replene (S.), heptane [37°) (T.), octane (S.), a valerylene (50°) (C.), cymenes (170°–178°) (K.), heptinene C, Π_a (104°) (R.), colophenone $C_{11}H_{18}O_a$ (S.) (97°), a terpene (160°) (S.), abietic acid (K.), isobutyric and methyl-propyl-acetic acids (K.), hydrocarbons $C_{11}H_{10}$ (190°–200°) (K.), and iso-butyric aldehyde (T.). Renard (A. Ch. [61, 1, 223]) found among the products of distillations. [6] 1, 223) found among the products of distillation of colophony (rosin oil), pentane, amylene, hexane, hexylene, toluene, toluene tetrahydride, toluene hexahydride, xylene, xylene tetrahydride, xylene hexahydride, m-ethyl-propyl-benzene, terpenes, isobutyric aldehyde and acid, and valeric aldehyde and acid. Lwoff (B. 20, 1017) found, in resin cel, valeric, heptoic, ennoic, and hendecoic acids. Resin oil is coloured violet by Il₂SO, of S.G. 1.53 (Holde, C. C. 1888, 952).

Resin of Pinus Laricio (Poir). [c. 100°]. V. sol. alcohol, ether, and oil of terpentine; insol. ligroin. Contains much methoxyl (Bamberger, M. 12, 441). Turned red by air, and finally brown. It contains a little free caffere acid C. H. (OH) . CH: CH. CO. H [195°] and ferulic acid [4:3:1] C. H. (OH) (OMe). CH: CH. CO. H [169°]. 4 p.c. of caffere and 1 p.c. of ferulic acid may be extracted by boiling with water. The resin also contains some vanillin Calla(OH)(OMe).CHO. The resin yields pyrocatechin and protocatechuic

acid on fusion with potash.

Resin of Picca vulgaris (Link). [c. 100°]. Contains methoxyl (Bamberger, M. 12, 456). Contains p-coumaric acid and vanillin. Potashfusion gives protocatechuic and p-oxybenzoic . acids.

Resin of Pinus sylvestris contains an acid $C_{10}H_{20}O_5$ [143°], insol. water, v. sol. alcohol, ether, and HOAc. $[a]_j = -74^\circ$. It yields the salts $C_{20}H_{20}A_5O_3$, $(C_{20}H_{20}O_3)_2Ba$ 2aq, $(C_{20}H_{20}O_3)_2C_4$, and $(C_{20}H_{20}O_{3})_{2}Cu$, and oily $C_{20}H_{20}EtO_{3}$, which on distillation forms oily $C_{20}H_{2}$, EtO_{2} . Alcoholic HCl converts the acid into an isomeride [160°]. $[\alpha]_i = -93^{\circ}$ (Shkateloff, J. R. 20, 477).

Resin from Ficus rubiginosa contains 'sycoceryl acetate ' C₃₄H₃₀O₂ [121°] which on saponification gives acetic acid and sycoceryl alcohol C₃₂H₅₄O [114°] (De la Rue a. Müller, *Tr.* 1860,

43; Kennie a. Goyder, C. J. 61, 916).

896 RESINS.

Formation.-1. By potash-fusion from galbanum (Hlasiwetz a. Barth, A. 130, 354), m-iodo-phenol (Körner, Bl. [2] 7, 261), phenolp-sulphonic acid (Glutz, Bl. [2] 8, 361), p-chloro-benzene sulphonic acid (Oppenheim a. Vogt, A. Suppl. 6, 376), from umbelliferone (Hlasiwetz a. Grabowski, A. 139, 99), from asafætida, from gum ammoniac, from sagapenum, from acaroid resin (Hlasiwetz, A. 130, 354; 138, 63; 139, 78), from o., m., and p. bromo-phenol (Fittig a. Mager, B. 8, 362), from p.-chloro-phenol (Faust, B. 6, 1022), from p-iodo-phenol above 165° (Nölting a. Wrzesinsky, B. 8, 820), from phenol (Barth a. Schreder, B. 12, 420), and from benzene m. or p. disulphonic acid (Barth a. Senhofer, B. 8, 1483; Fahlberg, Am. 2, 195).-2. By dry distillation of brazilin (E. Kopp, B. 6, 446). 3. By the action of nitrous acid on m-amidophenol (Bantlin, B. 11, 2101).

Preparation .- By fusing benzene m-disulphonic acid with NaOH (Müllhäuser, D. P. J.

263, 154).

Properties .- Colourless trimetric tables (from water, alcohol, or ether); $a:b:c = 912:1:1\cdot059$ (Calderon, C. R. 84, 779) or needles (from benzene). V. sol. water, alcohol, and ether, insol. chloroform and CS. Acquires a reddish tint on exposure to air. Neutral to litmus. Has a sweet taste. FeCl, colours its aqueous solution dark violet. Its ammoniacal solution, exposed to the air, becomes rose-red and finally brown. The ammoniacal solution leaves on evaporation a dark-blue mass, which forms a blue solution, turned red by acids. Bleaching-powder gives a transient violet colour. A drop of a solution of NaOCl gives a violet colour, quickly changing to yellow, and on heating to dark-red or brown (Stark, Ph. [3] 21, 848; Boddé, Ar. Ph. [3] 27, 656). Resorcin reduces boiling ammoniacal AgNO, and boiling Fehling's solution. On heating resorcin with a few drops of nitro-benzene and conc. H,SO, a blue mass is got which, when poured into water and made alkaline, gives a solution with vermilion fluorescence. If resorcin is added to conc. H.,SO, and a little NaNO,, and the mixture is heated to 100°, a product is got which, when mixed with water and rendered alkaline by NH_s, imparts to fusel oil a crimson colour with vermilion fluorescence (Bindschedler, M. 5, 168). Resorcin fused with phthalic anhydride forms fluorescein, which dissolves in aqueous alkalis with strong green fluorescence (Baeyer, A. 183, 8). Resorcin heated with alcohol, beet-sugar, and HClAq gives a reddish-violet colour (Ihl, Chem. Zeit. 13, 264). A solution of resorcin (1 pt.) in absolute alcohol (2 pts.), mixed with an aldehyde and a few drops of conc. HClAq, gives, after standing for some hours and then pouring into water, a resinous or crystalline pp. (Michael a. Ryder, Am. 9, 134). A mixture of resorcin and furfuraldehyde touched with a drop of HCl gives an indigo-blue substance, which dissolves with green colour in water, and is ppd. by HCl in blue flakes (Baeyer, B. 5, 25). On warming a liquid containing chloral or chloroform with resorcin and NaOH s yellowish-red colour with green fluorescence is got (Schwarz, Fr. 27, 668). Cupric sulphate and excess of ammonia form a deep-black liquid, which dyes wool black (Wagner, D. P. J. 220,

Titration.—1. Bromine-water is run in until all the resorcin is converted into tribromo-resorcin, which is ppd.: $C_6H_4(OH)_2 + 3BF_8 = C_6HBr_4(OH)_2 + 3HBr$. The excess is determined by adding KI and titrating with hyposulphite (Degener, J. pr. [2] 20, 322).—2. Potash and potassium iodide are added to the solution, and then a neutral solution of bleaching-powder is run in. On adding HCl a pp. of tri-iodo-resorcin is formed, and the excess of iodine is

titrated by hyposulphite (Degener).

Reactions.—1. Soda-fusion gives phlorogluein (65 p.c.), some pyrocatechin (3 p.c.), and tetra-oxy-diphenyl (1 p.c.) (Barth a. Schreder, B. 12, 503).—2. Exhaustive chlorination in presence of I forms CCl₄ and CO₂ (Ruoff, B. 9, 1483) .- 3. ICl forms tri-iodo-resorcin (Michael a. Norton, B. 9, 1752).-4. An alkaline solution gives with KI a violet-red pp. of C6H2I3KO2 (Messinger a. Vortmann, B. 22, 2320).-5. A solution of resorcin (10 g.) in water (100 c.c.) gives a purple colour with 5 c.c. of very dilute solutions of nitrates, to which a drop of 15 p.c. HClAq and 2 c.c. of H₂SO, have been added (Lindo, C. N. 58, 176).—6. Resorcin (15 g.) dissolved in water (70 c.c.) and warmed with a mixture of (60 c.c. of) HBrAq (S.G. 1.47) and (20 c.c. of) HNO₃ (S.G. 1.39) gives C₄₈H₃₃BrN₂O₁₃ as a lustrous violet mass, which forms a red solution in alcohol, changed by alkalis to a blue liquid (Brunner a. Krämer, B. 17, 1873; 21, 2481). It yields C4, H20Ac6BrN2O13 as an orangered amorphous powder [120°], v. sol. hot alcohol.

7. Resorcin (15 g.) heated with water (60 g.),
HNO₃ (20 c.c. of S.G. 1·39), and HCl (60 c.c. of S.G. 1.2) for half an hour on a water-bath forms a violet mass $C_{ss}H_{4s}ClN_{s}O_{1s}$, insol. chloroform, sol. alcohol and ether. It yields yellowish-brown flocculent $C_{66}H_{10}Ac_{g}ClN_{3}O_{18}$ (Brunner, B. 21, 2479).—8. A blue colouring matter (lacmoid) is got by heating resorcin (55 pts.) with NaNO₂ (18 pts.) at 130°, dissolving in NH3Aq and reppg. by HCl (Benedikt a. Julius, M. 5, 534).—9. Bromine in CS₂ forms C₆H₂Br₂(OH)₂ [111°] (Zehenter, M. 8, 293).—10. With Al₂Cl₈ it gives the compound (C₆H₄O₂)Al₂Cl₄, which is v. sol. hot CS₂, less sol. cold CS₂; decomposed at once by water into resorcin, Al₂O₃, and HCl (Claus a. Merklin, B. 18, 2934).—11. Dry ammonia passed into a solution of resorcin in dry ether forms (CaHaO2)NH2, which separates as a liquid, solidifying as colourless deliquescent crystals, turning green and afterwards blue in the air (Malin, A. 138, 80).-12. H₂O₂ and NH₂Aq give, after acidification, a brown pp. ('lacmoid') which forms an indigo blue solution in alkalis (Zulkowsky a. Peters, M. 11, 243; cf. Wurster, B. 20, 2934).—13. Animonium carbonate solution at 125° forms (4,2,1)and (6,2,1)- di-oxy-benzoic acid (Senhofer a. Brunner, Sitz. W. [2] 80, 504).-14. Ammoniacal CaCl₂ at 300° forms a brownish-red colouring matter [72°], insol. water and alkalis, sol. alcohol (Seyewitz, C. R. 109, 946).-15. Sulphur and NaOHAq form, on boiling, C₆H₄O₂S₂, a yellow powder, sol. alkalis, insol. water, and decomposing before fusion (Lange, B. 21, 263) .-16. K₂S₂O₇ acting on potassium resorcin forms C₅H₄(OH)(O.SO₂K) and C₅H₄(O.SO₃K)₂. The latter salt is converted, by heating in the dry state at 160°, into a salt of resorcin disulphonic acid (Baumann, B. 11, 1911). -17. COCl. forms

C.H.: CO, a red amorphous substance, insol. water, v. sol. alcohol (Birnbaum, B. 14, 1753).-18. An alcoholic solution of potassium xanthate forms $C_0H_1(OH)_2CS_2H$, crystallising in yellow needles [131°], sol. hot water (Lippmann a. Fleissner, M. 9, 296).—19. Acctone dicarboxylic acid and conc. H.SO, form (8) umbelliferone acctic acid C(OH): CH.Cl.O.CO CH = CH.Cl.C.(CH₂CO,H) CH [202], crystallising in needles (containing aq), insolether (Michael, J. pr. [2] 37, 469).—20. Benzene sulphonic chloride added to a solution kept slightly alkaline forms CoH4(O.SO2CoH5)2, crystallising from hot alcohol in needles [70°] (Georgesen, B. 24, 417).—21. Hydrogen ammonium o-sulphobenzoic acid forms C13H13NSO 2aq as pale-yellow crystals, v. sol. water and alcohol. Its alkaline solutions are slightly fluorescent. Conc. HClAq at 220° reconverts it into the parent substances (Fahlberg a. Barge, B. 22, 754). Resorcin (4 mols.) heated with o-sulphobenzoic acid (1 mol.) forms C31H20NSO8 4aq.-22. Chloro-acetic acid forms C.H.(O.CH, CO.H) [194°], which yields a di-bromo- derivative (Gabriel, B. 12, 1640).—23. ClCo₂Et acting on C₆H₄(OK)₂ forms C₈H₄(O.CO₂Et)₂, a thick oil (300°) (M. Wallach, A. 226, 84).—24. Dry oxalic acid (1 mol.) in a scaled tube at 200° forms 'resorcin-oxalein' C₂₀H₁₄O₂, a hygroscopic red powder, sol. alcohol and ether (Claus, B. 10, 1305; 14, 2563). At 100° it becomes $C_{20}H_{12}O_{6}$, which is less sol. alcohol. Dilute alkaline solutions are yellow, with dark-green fluorescence. Bromine gives $C_{20}H_1Br_2O_g$. HNO, forms $C_{20}H_0(NO_g)_Q$. H_2SO_g yields $C_{20}H_0(SO_g)H_0O_g$. Ac. O forms red $C_{20}H_{10}Ac_1O_g$ and colourless $C_{20}H_0Ac_1O_g$. $C_{20}H_0Ac_1O_g$. $C_{20}H_0Ac_1O_g$. $C_{20}H_0Ac_1O_g$. $C_{20}H_0Ac_1O_g$. $C_{20}H_0Ac_1O_g$. heated with resorcin (2 mols.) at 120° yields two compounds C14H2O3 one of which fluoresces green in alkaline solutions (Gukassianz, B. 11, 1184). 26. HOAc and ZnCl₂ at 145° form di-oxy-acetophenone. Resorcin (100 g.) boiled with HOAc (200 g.) and ZnCl₂ (300 g.) for two hours forms 'acetiluorescein' $C_{2}H_{18}O_{3}$ and 'resacetein' $C_{1e}H_{12}O_{4}$. Resacetein crystallises by spontaneous evaporation of its ammoniacal solution in red needles. Its solution in KOHAq is red, but soon turns brown. It yields the salts B'HCl 2aq and B'2H,SO, (dried at 110°) and a triacetyl derivative C₁₆H₉Ac₂O, [229°]. Acetiluorescein forms minute brownish-red crystals. Its dilute alkaline solutions exhibit green fluorescence (Nencki a, Sieber, J. pr. [2] 23, 540; Rasiński, J. pr. [2] 26, 58).—27. Resorcin (20 pts.) heated with formic acid (10 pts.) and ZnCl₂ (20 pts.) for 30 minutes at 140° forms 'resaurin' $C_{19}H_{14}O_6$ or $(C_6H_3(OH)_2)_2C < \stackrel{V}{C_0H_3(OH)}$. Resaurin is a brick-red hygroscopic powder, forming a red solution in alkalis, sol. alcohol, insol. ether and acids (Nencki a. Schmid, J. pr [2] 23, 517) .- 28. On heating with ZnCl, and [2] 23, 547).—28. On heating with 2nU₁ and acctoactic ether or oitric acid 'resocyanin' is formed (Wittenberg, J. pr. [2] 24, 125; 26, 74; Schmid, J. pr. [2] 25, 81). Resocyanin can be prepared by heating dry citric acid (60 g.) with resorcin (60 g.) and H₂SO₄ (150 g.) for an hour at 180°. Resocyanin C₂H₁O₂ [185°] is insol. cold water, sl. sol. ether, v. sol. alcohol. Its alkaline solutions are colourless with blue fluorescence. Its solutions are not

coloured by FeCl₂. It yields $\mathbf{C}_{21}\mathbf{H}_{12}\mathbf{Br}_{4}\mathbf{O}_{6}$ [250°] and $\mathbf{C}_{21}\mathbf{H}_{14}\mathbf{k}\mathbf{c}_{2}\mathbf{O}_{6}$ [150°]. Resocyanin yields resord when fused with potash. It may be reduced to a hydride C₂₁H₂₀O₆ [259°] which yields C₂₁H₁₈Ac₂O₆ [222°]. NaOMe and MeI give $C_{21}H_{18}Ac_2O_6$ [222°]. NaOMe and MeI give $C_{21}H_{18}Me_2O_6$ [159°].—29. A cold alcoholic solution of sodium malonic ether forms C, H,O [191°], which is v. sol. hot alcohol, insol. cold water. Its alkaline solutions are fluorescent. It splits up when heated above 191° into CO, and methyl-umbelliferone (Michael, Am. 5, 434 J. pr. [2] 35,455; 37,469).—30. Resorcin (7 pts.) heated with phthalic anhydride at 200° forms FLUORESCEÏN (vol. ii. p. 557).—31. Resorcin (2 mols.) heated with phthalimide (1 mol.) and H₂SO, at 100° forms C₂₀H₁₃NSO,, a light-yellow powder, insol. benzene and ether, v. sol. alcohol. It forms $C_{20}H_{12}NaNSO$, 7aq and $C_{10}H_{11}Ac_{2}NSO$, a yellowish-green crystalline powder (Ostersetzer, M. 11, 425).—32. g-Benzoyl-benzoic acid forms, on heating, di-oxy-tri-phenyl-carbinol carboxylic anhydride (v. vol. iii. p. 738) .- 33. Maleic anhydride forms, on heating, maleïc-fluorescein $CH:CH > C < C_0H_3(OH) > O$, which exhibits deep green fluorescence in alkaline solution and gives crystalline C₁₆H₈Et₂O₅ and C₁₆H₈Ac₂O₅ [157°] (Burckhardt, B. 18, 2864).—34. Succinic acid (13 g.) heated with resorein (20 g.) and H.SO₄ (40 g.) at 195° forms 'succinyl-fluorescein' $C_{ls}H_{12}O_s$ or $CH_{...}CH_2 > C < C_sH_{...}(OH) > O$, which is crystalline (containing 3aq) and fluoresces in alkaline solution. It yields $G_nH_nBr_nO_s$ (Nencki a. Sieher, J. pr. [2] 23, 153).—35. Tartaric acid 1 mol.) heated with resorcin (2 mols.) and H2SO, (1 p.c.) at 165° forms resorcin-tartrein, a dark olive-green powder, which fluoresces in alkaline solution (Fraude, B. 14, 2558).-86. Na₂CO₃ added to a solution of resorcin and quinone forms a deep-green solution changing through yellow to brownish-red on shaking with air (Wurster, B. 20, 2934).—37. Heated with aniline and CaCl₂ it yields m-oxy-di-phenylamine. With aniline and ZnCl, it yields diphenyl-m-phenylene-di-amine (Calm, B. 16, 2786; cf. Merz a. Weith, B. 14, 2345).—88. Aldehyde in presence of weak acids forms C1.H1.O4 or CH₃.CH(O.C₅H₄.OH)₂, yellow crystals, insol. water and other, sol. alcohol. At 120° this body is converted into brown crystalline C22H23O7. By heating the compound C₁₄H₁₁O₄ with zinc-dust in a current of hydrogen at 300°, resorcin is produced. Ac₂O at 140° gives C₁₄H₁₂Ac₂O₁ [282°] (Causse, Bl. [2] 47, 89; J. Ph. [5] 13, 354).—39. Chloral hydrate in aqueous solution containing NaHSO, forms silky needles of C14H12O6, insol. water and benzene, sol. ether and alcohol. Its alkaline solutions are fluorescent. It yields a diacetyl derivative [252°] (Causse, Bl. [3] 3, 861). Resorcin and glyoxylic acid yield the same $C_{11}H_{12}O_2$. By boiling chloral hydrate (5 pts.) with resorcin (10 pts.) and water (40 pts.) there is formed $C_0H_0O_3$ crystallising from dilute alcohol in yellowish needles, and yielding C_bH_bAc_bO_b [159°] and C_bH_bBc₂O₃ [165°] (Michael a. Comey, Am. 5, 350).—40. Benzoic aldehyde, alcohol, and a little HCl give C28H20O, xaq [above 330°], a colourless resin, insol. water, v. e. sol. alcohol. Its alkaline solution absorbs oxygen from the air. Ac O and NaOAc form Con Hi Ac O. HCl

converts it into the isomeric C26H20O4 4aq crystallising from alcohol in dimetric tables, reduced by sodium-amalgam to C₂₈H₂₂O₄ crystallising from alcohol in prisms, and converted by Ac.O and NaOAc into C_{2a}H_{1a}Ac.O crystallising from xylene in prisms (Michael, Am. 5, 840).—41. CH₂,CCl₂ and caustic soda form OH_3 . $C(O.C_6H_1.OOI_3$ and caustic soda form OH_3 . $C(O.C_6H_1.OOI_3$ [159°], v. sol. alcohol, sl. sol. hot water (Heiber, B. 24, 3684).—42. Camphor forms the compounds $C_6H_6O_2(C_{10}H_{10}O)$ [29°], $[a]_0 = 22\cdot5^\circ$, crystallising in hygroscopic rectangu-Lar plates, and C₂H₂O₂(C₁₀H₁₆O₁₂, a syrupy liquid, S.G. ¹⁶ 1.037; [a]_D = 25° (Léger, C. R. 111, 110).

48. Phenyl-hydrazine (2 mols.) rubbed with powdered resorcin (1 mol.) forms C₂H₂O₂N₂H₂Ph, crystallising in unstable satiny needles [76°], v. sol. benzene alcohol, and ether. It is decomposed by water and alkalis (Baeyer a. Kochendörfer, B. 22, 2195).—44. Quinone (1 mol.) added to a solution of resorcin (1 mol.) in hot benzene forms C₁₂H₁₀O₄ [c. 90°] crystallising in dark-red needles with green reflex, m. sol. water (Nietzki, A. 215, 136).-45. Cyanic acid passed into an ethereal solution of resorcin forms into an ethereal solution of resorein forms $C_8H_8N_2O_4$ [120°], sl. sol. ether, m. sol. hot water (Traube, B. 22, 1579).—46. Phenyl cyanate forms at 100° C_8H_4 (O.CO.NHPh)₂ [164°] (Snape, C. J. 47, 772).—47. Urea (2 pts.) in a current of CO_2 at 250° forms $C_{29}H_{29}N_1O_8$ (5aq, an olive-brown amorphous powder, melting above 360°, v. sl. sol but HOA2 and alkalis (Birnhamm, B. 13. sol. hot HOAc, sol. alkalis (Birnbaum, B. 13, 1619).—48. Heated with aqueous KHCO₃ or ammonium carbonate it yields di-oxy-benzoic acid.—49. Resorcin (1 pt.) mixed with acetone (2 pts.) and fuming HClAq (1 pt.) forms C₁₅H₁₀O₄ or CMe₂(O.C₆H₄.OH)₂, which crystallises in small prisms [213°], insol. water and ether, sol. KOHAq and Na CO Aq. It is decomposed by heat into acetone and resorcin. It forms a crystalline hydrate $C_{13}H_{16}O_{1}$ aq. Ac₂O yields $C_{13}H_{14}Ac_{2}O_{4}$ [126°] while BzCl gives $C_{13}H_{14}Bc_{2}O_{4}$ [115°] (Causse, Bl. [3] 7, 563).—50. Resorcin (20 g.) heated with K.CS, under pressure at 100° forms CH.S.O. [150°-155], sl. sol. CS., converted by potash-fusion into resorcin and (4,2,1)-di-oxybenzoic acid [205°] (Pribram a. Glücksman, M. 13, 626).

Mono-methyl ether C.H.(OH)(OMe). (244°). V.D. (H=1) 62·2 (obs.). Formed by heating resorcin (1 mol.) with KOH (1 mol.) and KMeSO, at 160° (Habermann, B. 10, 868). Formed also from resorcin, NaOMe, and MeI (Tiemann, B. 13, 2362; 14, 2019). Prepared by heating resorcin with MeOH and KHSO, for 10 hours at 180° (Wallach, B. 16, 151). Liquid, NaOHAq. Slightly volatile with steam. FeCl. colours its solution violet. Acetic anhydride forms C.H.(OAc)(OMe) (255°). KOH and K.S.O. form C₆H₄(OMe)(SO₄K), crystallising in plates, sol, water and hot alcohol.

sol. water and hot alcohol.

Di-methyl ether CaH4(OMe)x (215°)

**R. Schiff, B. 19, 562); (224°) (Stohmann).

**V.D. 68°8 (obs.). S.V. 157°13. S.G. 2 1°075.

**H.F.p. 74,034 [C,O₂ = 94,000; H₂₁O = 69,000]

(Stohmann, J. pr. [2] 35, 27). S.V. 157°1.

**Prepared by heating resorcin (1 pt.) with MeOH, KOH (1°5 pts.), and MeI (3 pts.) for 6 hours at 250° (Oechsner de Coninck, Bl. [2] 34, J49).

Oil, v. sol. alcohol and ether. Volatile with steam. Nct coloured by FeCl.

Methyl ethyl ether C.H.(OMe)(OEt). (216°). Formed from C,H,(OH)(OMe), KOH, and KEtSO, at 165°; the product being distilled with steam (Spitz, M. 5, 488). Liquid.

Methyl propyl ether C.H.(OMe)(OPr). (226°). Colourless liquid.

Methyl isobutyl ether C.H.(OMe)(OCH,2Pr). (234°). Liquid. Methyl isoamyl ether C.H.(OMe)(OC,H1). (236°). Liquid. Mono-ethyl ether C.H.(O

Mono-ethyl $C_oH_1(OH)(OEt)$. Liquid. HNO, saturated with nitrous acid added to its ethereal solution at 0° forms C_uH_z(NO₂)(OH)(OEt) and two colouring matters: C₂,H₂₀N₂O₂ [230°] crystallising in red needles, insol. water, sl. sol. boiling alcohol, forming a purple solution in H₂SO₄; and C₁₁H₁₁NO₂ [228°] crystallising in orange-red needles, forming a bluish-violet solution in H.SO, (Weselsky a. Benedikt, M. 1, 891).

 $C_{\epsilon}H_{\iota}(OEt)_{2}$. Diethyl ether (229°) (Pukall, B. 20, 1140); (235°) (Herzig a. Zeisel, M. 11, 300). Formed from resorcin, KOH, and Etl. Colourless prisms, volatile with steam. On adding one drop of KNO, solution followed by HClAq to its solution in HOAc, an intense emerald green colour is produced. Yields two di-bromo-derivatives [101°] and [77°]. Converted by dissolving in HOAc, adding NaNO₃, and passing in HCl into C₆H₃(NO)(OEt)₂ [123°] and C₈H₈(NO)(OH)(OEt), whence BzCl forms yellow crystals of C.H.(NO)(OEt)(OBz) [155°] (Kraus, M. 12, 374).

Hexa-chloro-di-vinyl ether

C₈H₁(OC₂Cl₃)₂. [54°]. Formed by heating C₈H₁(OAc)₂ with PCl₃ at 100° (Michael, Am. 9, 210). Long prisms, insol. hot water.

Di-propyl ether C₆H₄(OPr)₂. (251°). V.D. 702 (obs.). Liquid, m. sol. hot water, sol. alcohol, ether, and ligroin (Kariof, M. 1, 258; B. 13, 1677). Br forms C₆H₃Br(OPr)₂ [70°].

Mono-benzyl ether C.H.(OH)(OC,H.). Formed from resorcin, KOH, alcohol, and benzyl bromide (Schiff a. Pellizzari, A. 221, 376; G. 13, 504).

Di-benzyl ether $C_0H_4(OC_7H_7)_2$. [76°]. Glittering tables (from alcohol).

Tetra-nitro-di-phenyl ether
C_sH₁(O.C_sH₂(NO₂)₂)₂. [184°]. Formed from resorcin, NaOEt, and (1,2,4)-chloro-di-nitro-benzene in alcohol (Nietzki a. Schündelen, B. 24, 3586). Colourless plates. Converted by HNO, into a penta-nitro- derivative [68°], and by H2SO, and HNO, into the hexa-nitro-diphonyl ether [220°].

Di-acetyl derivative C₈H₄(OAc), (273°) (Nencki, J. pr. [2] 23, 147); (278° i.V.) (Typke, B. 16, 552). Formed from resorcin and AcCl (Malin, A. 138, 78). Oil.

Di-bensoyl derivative C.H. (OB2). [117°]. H.F. 124,598 (Stohmann, J. pr. [2] 36, 10). From resorcin (5 g.), benzoic acid (11 g.) and POCl. (13 g.), the latter being added slowly (Rasiński, J. pr. [2] 26, 64). Formed also by shaking resorcin with BzCl and NaOHAq (Hinsberg, A. 254, 254). Plates (from ether).

Anhydride C₁₂H₁₀O₂ i.e. O(C₂H₄·OH)₂. Resorcinyl oxide. Resorcin ether. Formed by heating resorcin with NaOH and CO₂ (Böttinger, B. 9, 182), with Na and CO₃ (Barth, B. 9, 308), with HClAq under pressure (Barth a. Weider, B. 10, 1464), or with H₃SO, (Barth, A. 164, 122; Kopp, B. 6, 447; Annaheim, B. 10, 976). Formed also by heating resorcin at 195° with the disulphonic acid of resorcin or of phenanthrene (Hazura a. Julius, M. 5, 191). Brownishred amorphous powder, acquiring by pressure a green metallic lustre. Nearly insol. water, v. sl. sol. cold alcohol and ether. KOHAq forms a dark red solution with green fluorescence. Potash-fusion reconverts it into resorcin. Oxidised by nitric acid to isophthalic acid. Yields C₁₂H₄Ac₂O₃, which forms a reddish-violet solution in alkalis, and C₁₂H₄Br₂O₃. Formed, together

Anhydride C₂₁H₁₈O₅. Formed, together with C₁₂H₁₀O₅, by heating resorein with HClAq at 180°. Brick-red powder, v. sol. alcohol and ether. Its alkaline solution is brownish-yellow with violet-blue fluorescence. Yields C₂₄H₁₆Ac₂O₅ and C₂₄H₁₂Br₂O₅. Oxidised by nitric acid to

isophthalic acid.

Resazurin C₁₂H₀NO₄ (B. a. K.), or C₁₂H₇NO₄ (Nietzki, B. 22, 3021; 24, 3366). Diazoresorcin. Azoresorcin. Resazoin. Formed by the action of nitrous acid on an ethercal solution of resorcin (Weselsky, B. 4, 613; M. 1, 889; 5, 607). Formed also by the action of MnO, and H,SO, on an alcoholic solution of resorcin and nitroso-resorcin. Prepared by adding furning HNO, (6 c.c.) to resorcin (10 g.) dissolved in ether (500 c.c.) at -7° , Dark-red prisms with green reflex. Insol. water and ether, v. sl. sol. cold alcohol and HOAc. Its alkaline solutions are bluish-violet. Conc. H2SO4 forms a red solution. HCl forms a crystalline hydrochloride. Yields Ba(C12H6NO4)2 crystallising in brown needles, and a sodium salt, which forms greenish needles, v. sol. water, sl. sol. NaOHAq, fluorescing brick red in dilute alcoholic solution. Resazurin forms C₁₂H₃Br₄NO₄ on bromination. Reactions.—1. AcCl in a sealed tube at 100°

forms C₁₂H₉Cl₂NO₃ (?) crystallising from HOAc in golden plates and amorphous $C_{26}II_{21}Cl_3N_2O_6$ (?) (Weselsky, A. 162, 288; Brunner a. Krämer, B. 17, 1854).—2. Conc. H₂SO, at 210° and conc. HClAq at 100° form resorufin.-3. On heating with tin and conc. HClAq an emerald-green solution is got, from which on cooling 'hydrodiazoresorufin hydrochloride ' separates as colourless leaflets or needles, which, when exposed to air, acquire a coppery lustre, and when heated in a current of air produce resorufin. Hydrodiazo-resorufin is dioxyphenoxazine, the formula being $C_8H_3(OH) < \stackrel{O}{\underset{NH}{\longrightarrow}} C_8H_3OH$ (Nietzki, B. 22, 3020). 4. Hot conc. HNO, forms 'tetrazoresorcin nitrate' C₁₈H₆N₇O₁₅ (?), crystallising in lustrous garnet-red needles, sol. water, alcohol, and ether with indigo-blue colour. According to Brunner a. Krämer (B. 17, 1864; 18, 587) these crystals are tri-nitro-resazurin $C_{12}H_a(NO_2)_3NO_4$. By heating them with conc. HNO, Weselsky obtained 'tetrazoresorufin nitrate' $C_{23}H_aN_{12}O_{21}(?)$, crystalliging from NHO in deals red conditions of from lising from NHO, in dark-red needles, and from wet ether in purple needles (containing 11 aq). Tin and HClAq acting upon either of these bodies form a red body, probably tri-amido-resorufin hydrochloride, and a colourless body, probably tri-amido-di-oxy-phenoxazine. By passing air through an ammoniacal solution of the colourless body there are formed lustrous green crystals of 'hydroimidotetrazoresorufin' C₃₈H₂₈N₁₄O, aq (W.) or C₁₈H₈(NH₃)₃NO₄ (B.) (possibly tri-amido-resorutin). — 5. Bromins added to its solution in NaOHAq forms (C₁₂H₃Pr₂NO₄)HBr as a lustrous green mass, forming a blue alcoholic solution with red fluorescence (Brunner a. Krämer, B. 17, 1862). Nietzki obtained C₁₂H₃Pr₄NO₄, which gave C₁₂H₃MaBr₄NO₄ 2aq, crystallising from dilute alcohol in lustrous green prisms.—6. Oxidised in KOH solution by H₂O, to oxyresazurin C₁₈H₂N₂O, (?), which forms almost colourless crystals giving a reddish-yellow solution in alkalis. This compound is also formed by alkaline KMnO₄. It is reduced by zinc-dust to C₁₈H₁₈N₂O, (?), crystallising in colourless needles (Ehrlich, M. 8, 425).

Acetyl derivative C₁₂H₆AcNO₄. [222°]. Formed by heating the sodium compound with NaOAc and Ac₂O at 100° (Nietzki, B. 22, 3024).

Ruby-red needles.

Ethyl ether C₁₂H_eEtNO₂. [215°]. Formed from the Ag salt, alcohol, and EtI. Dark-red needles. According to Weselsky the formula of the ether [202°] got from resazurin, alcohol, and HCl at 100° is C.H.Et.N.O.

HCl at 100° is C_{1s}H_sEt₂N₂O₆.

Resorufin C₁₂H₇NO₃ i.e.

CO.CH:CO.C.CH:COH CH:CH.C:N.C.CH:CH

resorufin.

Formation.-1. By heating resazurin with conc. H2SO, at 210 .- 2. By heating resorcin with a solution of nitrous acid in H.SO. (Brunner a. Krämer, B. 17, 1847).—3. By warming nitrosoresorcin with resorcin and H.SO, (Fevre, Bl. [2] 39, 593) .- 4. By heating resordin with nitrobenzene and H.SO, at 170°. -5. By the action of zinc-dust on an ammoniacal solution of resazurin (Weselsky a. Benedikt, M. 5, 608) .-6. By boiling resazurin (1 pt.) with FeCl. (2 pts.) and furning HClAq (10 pts.) and ppg. with water (W. a. B.).-7. By action of nitroso-phenol on resorcin or of nitroso-resorcin on phenol in presence of H.SO, (Nietzki, B. 22, 3020; 23, 718).-8. By adding MnO, to a solution of pamido-phenol and resorcin in conc. H2SO.

Properties. — Small dark-red grains (from dilute HClAq), insol. water and ether, sl. sol. alcohol. Forms a bluish-violet solution in H.SO. Alkalis form a crimson solution with scarlet

fluorescence.

Reactions.—1. Reduced by tin and HClAq or by zinc and HClAq to dioxy-phenoxazine C₁₂H₂NO₃, exystallising in nearly colourless needles, which soon become green in the air, and yielding C₁₂H₄Ac₂NO₃ [216*] crystallising in colourless needles, sl. sol. hot alcohol.—2. Bromine added to the alkaline solution yields the sodium salt C₁₂H₂Br₁NO₃Na 2aq, crystallising in lustrous green needles.—3. Nitric acid (8.G.1·37) forms a body crystallising in green needles, forming a purple solution in water, alcohol, and ether. This body is probably tri-nitro-resorufia. 4. Fuming HCl at 100° forms 'azoresorufyl chloride' C₂₁H₁₀Cl₁N₂O₃ (?) crystallising in red plates, sol. ether (Brunner a. Krämer, B. 17, 1857). Its alkaline solution exhibits red fluorescence.

Acetyl derivative C, H. AcNO. [228]. Formed by heating resorutin with Ac.O and NaOAc. Orange scales, v. sol. acetone, sl. sol. alcohol ar i ether.

Ethyl ether C, H, EtNOs. [225°]. Orangered needles (Nietzki).

Nitroso-resorcin v. vol. iii. p. 619. Diresoroin v. Tetra-oxy-diphenyl.

References .- AMIDO-, AMIDO-DI-IMIDO, BROMO-, DI-BROMO-AMIDO, BROMO-NITRO-, CHLORO-, IODO-, DI-IODO-NITRO-, NITRO-, NITRO-AMIDO-, and NITROSO-BESORCIN.

RESORCIN-BENZEÏN TETRA-OXY-TRI-PHENYL-CARBINOL.

RESORCIN CARBOXYLIC ACID v. Dr-oxy-BENZOIC ACID.

Resorcin (a)-dicarboxylic acid

C₆H₂(OH)₂(CO₂H)₂. [276°]. Formed, together with di-oxy-benzoic acid, by heating resorcin (1 pt.) with ammonium carbonate (4 pts.) and water (5 pts.) in a sealed tube (Senhofer a. Brunner, Bn. 2, 1266). Minute tables (from water), v. sl. sol. hot water. FeCl₃ colours its aqueous solution red. K1A"aq: needles.—K_2A"Baq: needles, v. e. sol. water.—BaA" 5½aq: needles.—CuA" 5 aq.—Ag.A": amorphous pp.

Resorcin (8)-dicarboxylic acid C_aH_a(OH)_a(CO_aH)₂. [250°]. Formed by heating (1,3,5)-di-oxy-benzoic acid with ammonium carbonate and water (S. a. B.). Four-sided prisms (containing aq), sl. sol. cold water. FeCl, colours its solution violet. - K2A".-Ba(HA")2 7aq.-BaA"4aq: needles. — Ba,C₈H,O₆2aq (dried at 160°). —PbC,H₄O₆ 1½aq.—Ca,M° 3½aq.

Resorcin dicarboxylic acid

 $C_6H_2(OH)_2(CO_2H)_2[4:2:5:1]$ (?). [192°]. Formed by oxidising the corresponding aldehyde [127°] (Tiemann a. Lewy, B. 10, 2212). Slender needles. Diresorcin dicarboxylic acid v. Tetra-oxy-

DIPHENYL DICARBOXYLIC ACID.

RESORCIN ALDEHYDE v. DI-OXY-BENZOIC

Resorcin dicarboxylic aldehyde v. Dr-oxy-

ISOPHTHALIC ALDEHYDE

RESORCIN-INDOPHANE C,H,N,O. Ppd., as K salt, by warming potassium tri-nitro-resorcin with aqueous KCy (Schreder, A. 163, 297). Small lustrous needles, forming a bluishviolet aqueous solution.—Na₂C₅H₂N₁O₆aq. — K₂C₅H₂N₁O₆aq: dark-brown lustrous crystals, exploding when heated.—BaC₁H₂N₁O₆aq. — DIRESORCIN-PHTHALEIN C₂H₂O₁O₅J₅laq

(Link, B. 13, 1654) or C₂₀H₁₂O₅ (Benedikt a. Julius, M. 5, 182). [245°]. Formed by heating diresorcin (tetra-oxy-diphenyl) with phthalic anhydride and SnCl₄ or H₂SO₄ at 115°. Silvery plates or needles, forming an indigo-blue solution in alkalis. Converted by heating with zincdust and caustic soda into diresorcin-phthalin C₃₂H₂₄O₁₀8½aq (L.) or C₂₀H₁₄O₆2aq (B. a. J.), crystallising from water in colourless plates [238°], forming a colourless solution in alkalis.
RESORCIN SULPHONIC ACID

C_eH₃(OH)₂(SO₃H). Formed by potash-fusion from the disulphonic acid (H. Fischer, M. 2,

337).-KA' 2aq : crystals.

Resorcin disulphonic acid C,H2(OH)2(SO3H)2. Prepared by sulphonation of resorcin (Piccard a. Humbert, B. 9, 1479; Tedeschi, B. 12, 1267). Deliquescent needles (containing 2aq), sol. water and alcohol, insol. ether. FeCl, gives a red colour. Gives phloroglucin on fusion with

potash. Bromine forms tri-bromo-resorcin even Pb_C,H_S,O, 4aq.

Resorcin disulphonic acid

C_eH₂(OH)₂(SO₃H)₂. Formed from di-amido-benzene disulphonic acid by the diazo- reaction (Limpricht, B. 8, 290). Long four-sided needles. BaA" 2aq : crystalline pp., got by adding alcohol to its aqueous solution.

Resorcin trisulphonic acid C₆H(OH)₂(SO₃H)₃. Formed by heating the disulphonic acid with fuming H₂SO₄ at 200° (Piccard a. Humbert, B. 10, 182). In neutral solution it gives a violet colour with FeCl.-Ba, A", 3!aq. Insol. water and HClAq.

References .- IODO-, NITRO-, and NITROSO-RESORGIN SULPHONIC ACID.

RESORCYLIC ACID v. DI-OXY-BENZOIC ACID. RESORCYLIC ALDEHYDE v. DI-OXY-BENZOIC ALDEHYDE.

Resorcylic dialdehyde v. DI-OXY-ISOPHTHALIC ALDEHYDE.

RETENE C₁₈H₁₈ i.e. CH.C₆H₁ [1:2] CH.C₆H₂MePr[1:2:6:3] Mol. w. 234. [98·5°]. (394°) (Schweizer, A. 264, 195). V.D. 8.3 (calc. 8.1) (Knecht, B. 10, 2074). S. (95 p.c. alcohol) 3 in the cold; 69 at 78°. S.G. (solid) 1.13 at 16°. H.C.v. 2,323,600. H.C.p. 2,326,100. H.F. -13,100 (Berthelot a. Vieille, A. Ch. [6] 10, 447). Occurs in scales in fossil pine-stems, accompanying fichtelite in peat bogs, and is a product of the distillation of wood (Fritsche, J. pr. 75, 281; Fehling, A. 108, 388; Wahlforss, Z. [2] 5, 73; Krauss, A. 106, 391; Ekstrand, Bl. [2] 24, 53; A. 185, 75; Bamberger a. Hooker, A. 229, 115). Produced by passing acetylene through a red-hot tube (Berthelot, J. 1866, 516). White plates, sol. alcohol, v. sol. hot HOAc, ether, and CS₂. Not attacked by potash-fusion or by alkaline KMnO₄. Dissolved by fuming HNO. It is not attacked by sodium-amalgam or HIAq at 200°. Reactions.—1. Absorbs chlorine, forming

C18H18Cl2, which splits up on heating into HCl and chloro-retene $C_{18}H_{17}Cl$, a crystalline body.— 2. Bromine and water form di-bromo-retene C18H16Br2 [180°] crystallising from CS2 in colourless tables. Excess of Br at 100° forms viscid $C_{18}H_{16}Br_4$ and crystalline $C_{18}H_{14}Br_4$ [212°].— 3. Oxidised by chromic acid mixture to retenequinone, phthalic acid, and HOAc. CrO, in HOAc forms retenequinone, retenic acid C18H18O2, and an acid C₁₆H₁₆O₃ crystallising from hot alcohol in plates [139°], forming NaA' and BaA'₂, both crystallising in plates.

Compound with picric acid C₁₈H₁₈C₄H₂(NO₂)₃OH. [124°]. S. (95 p.c. alcohol) 2·3 at 10°; 20 at 78°. Orange-yellow needles (from alcohol). Decomposed by water. Crystallises as $(C_{18}H_{18})(C_{6}H_{6})C_{6}H_{2}N_{2}O_{7}$ from benzene.

Compound with di-nitro-anthra-Dark orange-red needles (from quinone. HOAc).

Tetra-hydride C18H22. (280° at 50 mm.). Formed by adding Na to a solution of retene in isoamyl alcohol (Bamberger a. Lodler, B. 20, 3076). Pale-yellow liquid.

Dodeca-hydrids C₁₂H₃₀. (336° uncor.). Formed by heating retene with HI and P at 260° (Liebermann a. Spiegel, B. 22, 780). Colourless oil with bluish fluorescence. Vields no retenequinone when oxidised by HNO

Perhydride C₁₈H₃₂. [48°]. 719 mm. V.D. 8·69 (calc. 8·58). (335° i.V.) at This is probably the constitution of fichtelite (Bamberger a. Strasser, B. 22, 3361; Spiegel, B. 22, 3369; cf. vol. ii. p. 548). By heating with iodine it is converted into C₁₈H₃₀ (346° cor.) at 714 mm.

RETENE-FLUORENE v. METHYL-ISOPROPYL-

RETENE-GLYCOLLIC ACID C18H18O3 i.e. C₁₀H₁₀:C(OH).CO₂H. Formed by boiling retenequinone with NaOHAq (Bamberger a. Hooker, A. 229, 132). White crystals, sl. sol. hot water. -AgA': flocculent pp., sl. sol. hot water.
RETENE KETONE v. METHYL-ISOPROPYL-

DIPHENYLENE KETONE.

RETENEQUINONE C18H16O2 i.e.

 $CO.C_6H_4$ $CO.C_6H_2MePr$ Dioxy-Retistenequinone. relistene. [192°]. S. (95 p.c. alcohol) 15 at 0°; 2·2 at 78°. Formed by oxidising retene 0°; 2.2 at 78°. with CrO, in HOAc (Wahlforss, Z. [2] 5, 73; Ekstrand, A. 185, 75; Bamberger a. Hooker, B. 18, 1024; A. 229, 117). Orange-red prisms, v. sl. sol. cold alcohol and ether, sl. sol. aniline and HOAc, sol. benzene and chloroform. Not attacked by Cl in the cold. Not affected by hot HNO. Conc. H.SO, forms a green solution. Alcoholic potash imparts to its alcoholic solution a claret colour which disappears on shaking with air, but reappears on warming in absence of air.

Reactions.-1. Bromine forms C18H14Br2O2 [252°], crystallising from HOAc in orange prisms. 2. Cold NaOHAq does not dissolve it, but on boiling converts it into retene-glycollic acid.- On distillation with baryta it yields reteneketone and oily C_nH₂₄ (215-220°).—4. Distillation with zinc-dust forms retene.—5. HI and P reduce it to retene. - 6. In boiling alcoholic solution it is reduced by sodium-amalgam to retene diphenic acid $C_{16}H_{16}(CO_2H)_2$, an unstable resin yielding Ag_2A'' .—7. KMnO, forms oxy isopropyldiphenylene ketone carboxylic acid. -8. Phenyl-

ene-o-diamine forms $C_{1e}H_{1e} < \stackrel{C:N}{C:N} > C_0H_4$, crystallicing in really lising in needles [164°], insol. water, sl. sol. alcohol, v. sol. ether, resinified by strong acids. -9. Alcoholic ammonia added to a solution of the quinone in chloroform slowly forms the imide C18H18O(NH), crystallising in unstable golden needles.—10. Aqueous SO, forms hydroretene-quinone $C_{10}H_{10} < \begin{array}{c} C_{10}H_{1} \\ C_{10}H_{1} \end{array}$ crystallising in white

plates, sol. alcohol and alkalis. The same body is got by reducing the quinone with Zn and NaOHAq. It is oxidised by air to retenequinous.

Oxim C₁₈H₁₈O(NOH). [128.5°]. Golden

needles (from alcohol), decomposed by acids into the quinone and hydroxylamine. Forms green compounds with iron mordants (Von Kostanecki, B. 22, 1347).

RETENE DISULPHONIC ACID

C18H16(SO3H)3. S. c. 40 in the cold. Formed by sulphonation (Ekstrand, A. 185, 86). Needles (containing 10 aq), v. sol. water and alcohol. Its aqueous solution is ppd. by H₂SO₄, forming YOL IV.

H2A"5H2SO4, crystallising in hair-like needles .-K,A" aq (dried at 100'). S. c. 18. Small silky needles.—Na,A" aq (dried at 100'). S. c. 40 in the cold.—BaA" aq. S. 16.—SrA" 1 aq. S. 4.— CaA"8aq. S.5.—MgA"2aq (dried at 100°). S.4.-CuA' 5aq: long needles. S. c. 30.—PbA"aq (dried at 100°). S. 2.

Chloride C18H18(SO2Cl)2. [175°]. Prisms (from HOAc).

Retene trisulphonic acid C18H15(SO3H). Got by heating retene with fuming II.SO, at 100°. Crystalline mass, v. sol. water, alcohol, and ether; not ppd. by H₂SO₄.—Ba₂A'''₂18aq. Needles. S. 7.—Pb₃A'''₂18aq: slender needles. RETENIC ACID C₁₆H₁₆O₂. [222°]. A product of oxidation of retine (Ekstrand, A. 185, 111). Needles (from alcohol), v. sol. alcohol, ether, and HOAc. May be sublimed.-NaA: plates, m. sol. water.

RETINAPHTHA, is TOLUENE. RETINDOLE v. INDOLE.

RETISTENE is RETENE.

RHAMNETIN is the Methyl ether of

QUERCETIN (q.v.).

RHAMNITE $C_6H_{14}O_5$ i.e.

CH₃.CH(OH).CH(OH).CH(OH).CH(OH).CH₂OH. [121°]. [a]_D = 10.7°. Formed by reducing isodulcite with sodium-amalgam in a solution kept nearly neutral by H.SO. (E. Fischer a. Piloty, B. 23, 3104). Triclinic crystals, with sweet taste, v. sol. water and alcohol, sl. sol. chloroform, v. sl. sol. ether. Dextrorotatory. Does not reduce Fehling's solution.

RHAMNOHEPTOSE C,H1,O, СН(ОН).СН(ОН).СН(ОН).СН.

 $\frac{\mathrm{CH(OH).CH(OH).CH(OH).CHO}}{\mathrm{CH(OH).CHO}} \quad [\alpha]_D = 8^{\circ}.$ Formed by the action of sodium-amalgam on the lactone, [c. 160°], [a]_D = 55·6°, of hexa-oxy-octoic acid, which is formed from rhamnohexose by successive treatment with HCy and nexose by successive treatment with fley and baryta (Fischer a. Piloty, B. 23, 3106). Sweet syrup. Dextrorotatory. Yields C,II, O₆(N₂HPh) [200°] and C₈H₁O₅(N₂HPh)₂ [c. 200°]. Converted by treatment with HCy, followed by saponification, into hepta-oxy-ennoic acid CH(OH).CH(OH CH(OH).CH(OH).CH(OH).CH(OH).CO₂H the CH(OH).CH(OH).CH(OH).CH(OH).CO₂H the lactone of which [c. 172°] is levorotatory [a]_p = -51° .

RHAMNOHEXITE C.H.₁₁O₆ i.e.

ÇH(OH).CH(OH).CH(OH).CH3 [c. 173°]. CH(OH).CH(OH).CH₂(OH)

[a]₀ = 11.6°. Formed by reducing rhamnohexose with sodium-amalgam (Fischer a. Piloty, B. 23, 3106). Small colourless prisms (from hot alcohol). Does not reduce Fehling's solution.

RHAMNOHEXOSE C. $H_{14}O_{g}$ i.e. $GH_{a}CH(OH).CH(OH).CH(OH).CH(OH).CH(OH).CH(OH).CH(OH).CH(OH).CH(OH).CHO$. [181°]. [a]_D = -61°. Formed by reducing the lactone of isodulcite carboxylic acid with sodiumamalgam in acid solution at a low temperature (Fischer a. Piloty, B. 23, 3104). Small tables, sl. sol. alcohol. Its aqueous solution tastes sweet. Yields a di-phenyl-di-liydrazide [200°].

RHAMNOSE V. ISODULGIES.
RHATANINE C₁₀H₁₂NO₂. S. 8 at 100°.
S (alcohol) 01 at 15°; 04 at 76°. Occurs in the extract of rhatany root (Wittstein, J. 1854, 656; Ruge, Viertelj. d. nat. Ges. in Zürich, 6, Hett 3; Gintl, Sitz. W. [2] 60, 668; Kreitmair, 4. 176, 69). Spherical groups of white needles,

insol. ether. Not ppd. by lead acetate or subacetate. Resembles tyrosine. On heating with a little solution of Hg(NO₃)₂ it becomes rose-red, and gives a brown pp. on further addition of Hg(NO₃)₂. Boiling HNO₃ gives a red colour changing to blue, and finally to a fluorescent green. Sulphuric acid forms a sulphonic acid $C_{10}H_{12}NO_3(SO_3H)$ aq crystallising from alcohol in

Salts.—H₂\(\alpha''\)HCl: monoclinic prisms, decomposed by treatment with water or alcohol.— (H₂A")₂H₂PtCl_e.—Na₂A": deliquescent amorphous mass.—K₂A".—BaA" 2aq.—SrA" 2aq. phous mass.—A.A. .—Ban zuq.—Gra zuq.—CaA".—MgA".—Ag.A": minute needles, sl. sol. cold water.—H.A"H.YO.,: trimetric crystals.—H.A"H.,PO.; small prisms.

RHATANITANNIC ACID C.,0H.20, (Raabe,

J. 1880, 1060). Occurs in rhatany extract from the root-bark of Krameria triandra (Wittstein, J. 1854, 656; Grabowski, A. 143, 274). Amorphous, sol. water. Reduces Fehling's solution. Gives a dark-green colour with FeCl. Yields phloroglucin and protocatechuic acid on fusion with potash. 'Boiling dilute H2SO, forms 'rhatania-red ' C20H18O8, which yields pyrocatechin on distillation.

RHINACANTHIN C14H18O4. Occurs in the root of Rhinanthus communis (Liborius, J. 1881, 1022). Tasteless resin, sol. alcohol. Does not

form glucose on boiling with HClAq.

RHINANTHIN C29H32O20 (L.) or C81H38O400 A glucoside occurring in the seeds of the yellow rattle (Rhinanthus crista-galli), and giving rise to the violet colour of bread prepared from rye contaminated with these seeds. Occurs also in the seeds of Alectrolophus hirsutus (Ludwig, Z. [2] 5, 303; Ar. Ph. [2] 142, 199), and in the leaves and stalks of the snap-dragon (Anti-rhinum majus) (Phipson, C. N. 58, 99). Stellate groups of prisms, with bitter-sweet taste, v. sol. water and alcohol. Gives a bluish-green solution on warming with alcoholic HCl. Resolved by dilute HClAq into brown amorphous rhinanthogen and a sugar.

RHIZOPOGONIC ACID C25H36O4. [127°]. Obtained from the mushroom Rhizopogon rubescens by extracting with ether (Oudemans, R. T. C. 2, 155). Red needles, insol. water, v. e. sol. ether, chloroform, and boiling alcohol. alkaline solutions are intensely violet.—KA' aq:

minute dark-violet crystals.

RHODAMMINES RHODIUM-AMMONIUM COMPOUNDS, p. 405.

RHODANIDES, another name for Sulpho-

cyanides (q. v. vol. ii. p. 348).

RHODÂNIC ACID C,H,NS2O i.e.

HS.CH,CO.S.CN or CH2

CO.NH (Andreasch, M. 10,73). [169°]. Formed by warming an aqueous solution of chloro-acetic acid (1 mol.) with ammonium sulphocyanide (3 mols.) (Nencki, J. pr. [2] 16,1; B. 17, 2279; Ginsberg a. Bondzynski,
 B. 19, 113). Formed also by passing HCl into an alcoholic solution of thioglycollic acid and otassium sulphocyanide (Freydl, M. 10, 82). potassium suipnocyanius (riejui, Yellow six-sided prisms and tables, v. sl. sol. cold water, v. sol. alcohol and ether. Acid in reaction. Boiling baryta-water splits it up into HCyS and thioglycollie acid. Water at 200° forms CO₂, H₂S, NH₃, and thioglycollie acid. Reacts with aldehydes in presence of HCl, form-

ing compounds of the type R.CH:C(SH).CO.S.CN. Ethylidene-rhodanic acid C,H,NS,O [148°] forms yellow needles, sol. hot water. Benzylidene-rhodanic acid C10H,NS2O [200°] also forms yellow needles, converted by hot H2SO4 (4 pts.) into C10H7NS2O3, crystallising in needles, yielding NaA', KA', and NH,A', and converted by HNO₃ nto C₁₀H_aN₂S₂O₇, crystallising in yellow needles yielding NaA' aq. o-Nitro-benzylidene-rhodanic acid C₁₀H_aN₂S₂O₃ [189°] crystallises from dilute alcohol, and may be reduced to o-amido-benzylidene-rhodanic acid, which yields C₁₀H₁AcN₂S₂O [280°-285°] and C₁₀H₆Ac₂N₂S₂O [189°]. p-Nitro-benzylidene-rhodanic acid [252°] is also crystalline (Bondzynski, M. 8, 357). FeCl, added to a hot solution of rhodanic acid forms a brown pp., from which alcohol extracts C₂H₃N₃S₅O₃ as a brownish red powder, forming a red solution in alkalis.

Salts.—CuA', aq: yellowish-green amorphous pp.—(C₃H₃NS₂O), CuCl: golden needles. RHODATES. No salts have been isolated the acidic radicle of which is composed of Rh and O; but there is some reason to think that such salts exist in the solution obtained by passing Cl into an alkaline solution of Rh2(OH),; v. under Hydrated rhodium dioxide, p. 405.

RHODINOL C₁₀H₁₈O i.e. CH₂·C(C₂H₂).CH:CH.CH.Me.CH₂OH. (217°). S.G. 1¹⁵·88. Occurs in German and Turkish oil of roses (Eckart, B. 24, 4205). Oxidised by chromic acid mixture to an aldehyde, rhodinal, and rhodinolic acid. P2Os yields a terpene. KMnO4 forms valerio, butyrio, acetic, oxalic, and carbonic acids and C₆H₁₄O_a, possibly an alcohol.

RHODIUM. At. w. 102-7. Mol. w. unknown. Melts at c. 2000° (Pictet, C. R. 88, 1317). S.G. 12·1 (Deville a. Debray, J. 12, 240). S.H. 05803 (10° to 97°; specimen contained trace of Ir) (Regnault, A. Ch. [3] 63, 1). C.E. 0000085 at

40° (Fizeau, C. R. 68, 1125).

Occurrence.-With the other Pt metals in platinum-ore; the p.c. of Rh varies from 0 to c. 5; as much as 12.3 p.c. was found in a South American ore by Deville a. Debray (A. Ch. [2]

29, 137; cf. Kern, C. N. 35, 88).

Del Rio (v. D. a. D., l.c.) found an alloy of Rh and Au in Mexico, containing from 34 to 43 p.c. Rh. Rhodium was separated from the other Pt metals in 1803 by Wollaston (T. 1804. 419), at the same time as he isolated Pd. The name rhodium was given by W. because of the rose-

colour of the salts (ρόδον = a rose).

Formation.—1. By reducing RhCl, 3NaClAq by Zn, H, formic acid, &c .- 2. By strongly heat-

ing RhCl 3.3NH Cl.

Preparation.—Rh is generally prepared by adding iron to the mother-liquors from which Pt has been extracted (v. Platinum, this vol. p. 286), and then treating the solid so ppd. The processes for the treatment of this residue are many; that described here is the one employed by Claus (J. pr. 85, 129), and by Gibbs (J. pr. 84, 65; 94, 19), and is a modification of Claus's older method (cf. Deville a. Debray, C. R. 78, 1782). The platinum-residue-which contains Rh, Ru, Pd, Ir, Cr, Cu, and Pb-is fused at a bright red heat with 1 pt. Pb and 1 pt. PbO; the regulus, after separation of slag, is treated with nitric acid (equal vols. conc. acid and water); the insoluble residue is washed, dried, and mixed

with its own weight of NaCl, and this mixture is heated to low redness, in a large porcelain tube, in a stream of Cl, for some time; the treatment with NaCl and Cl is repeated; after cooling, the contents of the tube are lixiviated with water, when RhCl₃.3NaCl dissolves with small quantities of the corresponding salt of Ir and traces of some of the other metals. The solution is heated with HNO3Aq, to transform IrCl, into IrCl, and Ir is then removed, as IrCl, 2AmCl, by fractional ppn. with conc. The filtrate from the last pp. of AmClAq. IrCl..2AmCl, which is almost quite free from all metals except Rh, is evaporated to dryness with HNO, Aq, to decompose the AmCl; the residue is mixed with 3 or 4 times its weight of S, and heated to bright redness in a covered porcelain crucible, which is packed in powdered charcoal in a larger earthen crucible. The regulus thus obtained is boiled for some time with aqua regia, and then with conc. H₂SO₄; it is then fused, at a low red heat, with 3 or 4 pts. Zn, whereby an alloy of Rh and Zn is formed, with the production of so much heat that part of the Zn is volatilised. After cooling, the alloy is digested with conc. HClAq, to remove impurities, and is then dissolved in aqua regia. NH, Aq is added to this solution till the pp. which forms has dissolved: the solution is boiled, and evaporated until yellow Rh2(NH3)10Cla separates; the whole is then evaporated to dryness at 100°, and the residue is treated with warm dil. HClAq until the washings show no yellow colour; the residue is dissolved in boiling water, and the liquid is filtered, hot, into dil. HClAq; the small yellow crystals of Rh2(NH3)10Cle which separate are re-crystallised several times from hot, dil. NH3Aq, whereby the salt is obtained quite pure. The pure Rh2(NH3)10Cl6 is decomposed by heating strongly in a graphite crucible, and the Rh thus obtained is fused in a lime crucible in the O-H flame (v. vol. iii. p. 642). The fusion removes the last traces of Os and Si. For other methods of preparing Rh v. Bunsen, A. 146, 265; Fremy, C. R. 38, 1008; Lea, Am. S. 38, 81, 248; Schneider, P. Supp. 5, 261; Philipp, D. P. J. 220, 95; Martius, A. 67, 357; Wilm, Bl. [2] 34,

Properties.—A very hard, white metal, with a tinge of blue-grey; about as ductile and malleable as Ag. Melts only in the full O-H flame, without volatilising; spits on cooling; is superficially oxidised when very strongly heated in air. Insoluble in acids when compact, but the finely divided metal ppd. from solutions is sol. HNO,Aq, and also sl. sol. HClAq in presence of air (Wilm, Bl. [2] 34, 679). Alloys of Rh with Bi. Cu, Pb, Pt, or Zn are attacked by HNO,Aq. Rh is obtained as a black porous solid by reducing solutions of Rh compounds by Zn, Hg, EtOH, or HCO,H (v. Claus, J. pr. 85, 139; Wilm, lc.). The finely divided Rh obtained by heating the purpureochloride takes up c. 13 p.c. O when heated in a stream of air (RhO requires 13-5 p.c. O), and the O is given up by heating in H.

In its chemical relationships Rh is closely allied to Ru and Pd, and less closely to Os, Ir, and Pt; v. Noble metals, vol. iii. p. 628.

The at. w. of Rh has been determined (1) by analyses of RhOl, 3KCl (Berzelius, P. 18, 442 other occupies when the reagents are added, [1828]); (2) by analyses of a large number of and comparing the two, 00019 g. Rh can be

different Rh compounds (Claus, J. pr. 85, 139 [1862]); (3) by analyses of Rh₂(NH₃)₁₆Cl₄ and Rh₂(NH₃)₁₆Cl₅ (Jörgensen, J. pr. [2] 27, 433, 489 [1883]); (4) by reducing pure Rh₂(NH₃)₁₆Cl₄ in H, and determining the residual Rh (Seubert a. Kobbé, A. 260, 314 [1890]); (5) by determining S.H. of Rh (Regnault, A. Ch. [3] 63, 1). No compound of Rh has been gasified. The older values for at. w. of Rh varied from 104'3 to 103. Seubert a. Kobbé have shown that the true value is less than 103.

Reactions and Combinations .- 1. Rhodium black heated in air combines with O to form RhO, according to Wilm (B. 15, 2225). Leidié (Bl. [2] 50, 664) says that the products contain from 14.5 to 17.8 p.c. O (RhO requires 13.5 p.c. O). -2. Oxidised to Rh₂O₃, and then to RhO₂, by fusion with potash and nitre (Claus, l.c.); also by heating strongly with barium peroxide (D. a. D., l.c.) .- 3. Fusion of Rh black with potassiumhydrogen sulphate produces what is probably a double Rh-K sulphate (Claus, l.c.). 4. Heated in chlorine to c. 400°, RhCl₃ is formed (v. Leidić, Bl. [2] 50, 664) .- 5. Mixed with scalium-chloride and heated in chlorine, RhCl, 3NaCl is produced; KCl and Cl, and BaCl, and Cl, act similarly (Berzelius, P. 13, 435; Bunsen, A. 146, 266).— 6. RhS is formed by heating Rh black in vapour of sulphur (B., l.c.).—7. Rh dissolves in molten phosphoric acid (Fischer, P. 18, 257), also in molten acid phosphates (Rose-Finkner, Hand. d. anal. Chem. 6th ed., 1,354). -8. Finelydivided Rh dissolves in molten zinc (Jörgensen, J. pr. [2] 27, 433, 489).—9. Hydrogen is absorbed in large quantities by Rh. The finely divided metal obtained by heating RhCl.3AmCl becomes sensibly hot when H is passed over it (Wilm, l.c.) .- 10. Rh black decomposes chlorine water, forming HClAq and O, and solutions of hypochlorites, forming chlorides and O (Jörgensen, l.c.). It also decomposes hydrogen peroxide, giving off O .- 11. Rh black decomposes formic acid solution to H and CO.; alcohol in presence of alkali is oxidised to alkali acetate, and H is given off, at c. 30° (D. a. D., A. Ch. [2] 29, 137; 56, 385; cf. Hoppe-Seyler, B. 16, 117).—12. When Rh black obtained by heating RhCl, 3AmCl is heated in coal-gas, or in ethylene, the volume of the Rh increases and C is absorbed (Wilm, Bl. [2] 34, 679).

Detection .- Rh may be brought into solution in water, either by repeated fusion with KHSO. or by mixing with NaCl and heating to low redness in Cl. To detect Rh in solution, Demarcay (C. R. 101, 951) recommends to add AmCl to a neutral, or an almost neutral, solution which has been boiled with HClAq, then to add fairly conc. freshly prepared NaClOAq, and then a 20 p.c. acetic acid solution, drop by drop, with constant shaking, till any pp. formed by the NaClOAq dissoves to an orange-coloured solution; on standing, this solution decolourises, deposits a greyish pp., and finally acquires an intense sky-blue colour, which remains for some time. Free HNO₃ or H₂SO₄ should be absent, not much acetic acid should be added, and the temperature should not be raised. By taking two equal portions of the liquid to be tested. diluting one with water to the same bulk as the other occupies when the reagents are added, detected in 3 c.c. liquid. The other Pt metals ! give no reaction with NaClOAq under the above conditions.

Rhodium, alloys of. Rh alloys with many metals, by fusion with them. Some of the alloys seem to have definite compositions, e.g. Rh.Pb and RhZn₂. Descriptions of the alloys will be found in the papers referred to:—As (Wollaston, T. 1804. 419); Bi (W., l.c.); Au (W., l.c.; van Riemsdyk, J. 1880. 1269); Fe (Faraday a. Stodart, G. A.: 66, 167); Pb (Debray, C. R. 90, 1195; Deville a. D., C. R. 44, 1101; 94, 1557); Pt (D. a. D., l.c.); Ag (W., l.c.); Sn (D., l.c.; Leidié, C. R. 106, 1076); Zn (D. a. D., l.c.; Bunsen, A. 146, 271; Jörgensen, J. pr. [2] 27,

Rhodium, ammonio-salts of, v. Rhodium-

AMMONIUM COMPOUNDS, p. 405.

Rhodium, chlorides of. The only chloride of Rh which has been isolated with certainty is RhCl. The lower chloride RhCl, probably exists.

RHODIUM DICHLORIDE RhCl2. This chloride probably exists. Berzelius obtained a greyishred powder, to which he gave this composition, by heating Rh in Cl, warming the product with KOHAq, and treating the hydrated oxide so formed with HClAq, when RhCl₃ dissolved and RhCl₂ (?) remained (P. 13, 437). According to Fellenberg (P. 50, 63) RhCl₂ is obtained, as a rose-red powder, insol. water, HClAq, or HNO, Aq, undecomposed by KOHAq, by heating RhS in Cl. Claus (J. 1855, 423) and Leidié (C. R. 106, 1076; 107, 234) regard the existence of RhCl2 as unproved. According to L., no substance of constant composition is obtained by F.'s method.

(?) Double salt, Am, RhCl, xH2O. The compound to which Wilm gave this composition, and which he said was obtained by adding AmCl to RhCl, Aq in presence of much aqua regia (B. 16, 3033), is almost certainly identical with Am, RhCl, NH, NO, 3, ILO, obtained by Leidié (v.

AMMONIUM CHLOR-RHODITE, infra).

REDDIUM TRICHLORIDE RhCl, (Rhodo-chloride, Rhodo-rhodic chloride, RhCl, RhCl, RhCl, is Rhodium sesquichloride, Rh2Cl6). the simplest formula possible, but it is not necessarily molecular. Leidić (C. R. 106, 1076; 107, 234) prepared RhCl, by heating the alloy RhSn, in a rapid stream of dry, airfree Cl at the B. P. of S, until SnCl, ceased to be formed, allowing to cool, and removing Cl by a current of CO₂. The chloride is thus obtained as a sealing-wax-red powder. The alloy RhSn, is formed by fusing 1 part finely divided Rh with 30 to 50 parts Sn, and treating the product for a day or two with fairly conc. HClAq at 0° (Debray, C. R. 104, 1470, 1577). RhCl, was also formed by Jörgensen (J. pr. [2] 27, 433) by heating Cl.Rh₂(NH₃)₁,Cl₄ in a stream of Cl. Leidié (Bl. [2] 50, 664) says that RhCl₃ is not obtained pure by Claus' method of heating Rh in Cl, as part of the RhCl₃ is decomposed at the temperature which must be employed to cause combination of Rh and Cl. Leidié (l.c.) could not obtain pure RhCl, by heating Rh,S, in Cl, nor by heating the double chlorides of Rh and alkali metals with H2SO4, as recommended by Claus; in the latter reactions L. obtained alkali sulphate and Rh₂(SO₄)₃. RhCl₃ is a red powder, insol. water and acids; decomposes to Rh and

Cl at c. 450°-500° (L., l.c.). When moist RhCl. is heated in vacuo, or in a stream of N, it is partially decomposed at 100°, and wholly at 360°, to Rh₂O₃ and HCl (L., l.c.). Slowly reduced by H at low redness (v. Claus, J. 1855, 423).

TRICHLORIDE HYDRATE RHODIUM OF RhCl.,4H.O. Said to be formed by Claus (l.c.) by dissolving freshly ppd. Rh(OH), in HClAq, and evaporating; by Berzelius (P. 13, 437) by decomposing K,RhCl₈Aq by H₃SiF₈Aq, filtering, and evaporating. Described as a dark-red, glassy, deliquescent solid; e. sol. alcohol, insol. ether. Leidié (Bl. [2] 50, 664) could not obtain this. nor any definite, hydrate of RhCls.

Double salts. Chloro-rhodites

RhCl₃·3MCl, or M_3 RhCl₅. M = Am, $\frac{1}{2}$ Ba, $\frac{1}{2}$ Pb, Hg, K, Ag, Na. Also M_2 RhCl₅; M = ?Am, and K.

Ammonium chlor-rhodite 2Am, RhCl, 3H, O (Ammonium-rhodium trichloride). Large, red, rhombic prisms (v. Keferstein, P. 99, 275); by adding cone. HClAq to Na,RhCl,Aq, filtering from NaCl, and adding conc. AmClAq (Claus, l.c.; Wilm, B. 16, 3033; Leidié, l.c.). Sol. water, or dil. AmClAq; insol. alcohol. The salt Am, RhCl., H.O. said to be formed by heating a solution of the preceding salt (Vauquelin, A. Ch. 93, 204), could not be obtained by Leidié (l.c.).

Double salt with ammonium nitrate, 2(Am,RhCl, NH,NO,).7H,O. Obtained, as violet-red crystals, by adding HNO, Aq to Am, RhCl, Aq, and then excess of AmClAq, concentrating, and drying the crystals in vacuo. Scarcely sol. HNO, Aq; when boiled with water gives off same gases as are obtained by boiling

AmClAq with aqua regia.

Potassium chlor-rhodites (1) K,RhCl, 3H,O. Dark-red triclinic prisms; by adding conc. KClAq to RhCl,Aq, and allowing to evaporate (Claus, l.c.). Obtained by Seubert a. Kobbé (B. 23, 2556) by saturating the filtrate from the salt K₂RhCl₃ (infra) with HCl, filtering from KCl, and evaporating. Leidić (l.c.) failed to obtain this salt.

(2) K2RhCl3.H2O (no water, according to L.). Brown triclinic prisms, sl. sol. water. Gives Rh, KCl, and Cl when heated to redness. Formed by heating a mixture of 1 part spongy Rh with 2 parts KCl, in a stream of Cl, so long as Cl is absorbed, dissolving in water, filtering, and evaporating under reduced pressure (S. a. K., *l.c.*).

Sodium chlor-rhodite Na, RhCls.9H,O. Prepared like the K salt (Berzelius, Claus, Leidié).

The lead, mercurous, and silver salts are obtained by adding Pb(NO₃),Aq, HgNO₃Aq, or AgNO Aq, to solution of an alkali salt (Claus, I.c.). The barium salt is obtained like the K and Na salts (Bunsen, A. 146, 276). Compounds of RhCl, with methylamine chlorides are described by Vincent (Bl. [2] 44, 513).

Rhodium, cyanides of, and derivatives, v. vol.

ii. p. 346.

Rhodium, hydrosulphide of, $RhS_3H_3(=Rh_2S_3.3H_2S).$ A brownish - black, voluminous pp., obtained by passing H2S into solution of a Rh salt at c. 100° (Leidié, Bl. [2] 50, 664). Insol. acids, or alkali sulphide solutions; decomposed by Br and aqua regia. Gives off H.S. and forms Rh.S. when boiled with much water in N, or when heated with water in a sealed tube to 100°.

Rhodium, hydroxides of, v. Rhodium oxides AND HYDRATED OXIDES.

Rhodium, iodide of. The black substance obtained by Jörgensen in making Rh2(NH3)10I4 (v. Iodopurpureorhodium iodide, p. 406) was probably RhI₃; analysis gave 21.8 p.c. Rh, the formula requiring 21.3 p.c. According to Claus (l.c.) an iodide of Rh is formed when KIAq is added to solution of a salt of Rh.

Rhodium, oxides and hydrated oxides of. Rh and O combine, when Rh is strongly heated in O, probably with formation of RhO. only oxides of Rh which have been isolated with certainty are Rh₂O₃ and RhO₂; RhO also probably exists, and there are indications of the formation of RhO₃. The hydrated oxides, or hydroxides, are Rh₂O₃SH₂O [=Rh(OH)₃], and $RhO_{2}.2H_{2}O = Rh(OH)_{1}$.

RHODIUM MONOXIDE RhO (Rhodous oxide). Probably formed when Rh black is heated in a stream of air (Wilm, B. 15, 2225). Leidić (Bl. [2] 50, 664) says that from 14.5 to 17.8 p.c. O is taken up; RhO requires 13.5 p.c. O. The grey powder obtained by heating Rh(OII), was looked on by Claus as probably RhO. Deville a. Debray (A. Ch. [3] 61, 83) obtained what they regarded as RhO containing a little PbO by melting Rh with PbO, Pb, and borax, cupelling, and treating the residue with IINO3Aq. RhO is said to be fairly easily reduced to Rh by heating in H.

RHODIUM SESQUIOXIDE Rh2O3 (Rhodo-rhodic This oxide may be formed when Rh oxide). black is heated to redness in air. Leidié found from 145 to 17.8 p.c. O taken up (BL [2] 50, 664); Rh₂O₄ requires 18.92 p.c. O. Rh₂O₃ was obtained by Claus (J. pr. 76, 24; 80, 282; 85, 129) by heating Rh(NO₄); in a Pt crucible till revides of N consell to the particular till. oxides of N ceased to come off; also by fusing Rh with BaO2 and Ba(NO3)2. Fremy (A. Ch. [3] 44, 385) says that Rh₂O₃ is produced by heating Na₃RhCl₆ to redness in a stream of O. Rh₂O₃ is also formed by heating RhO3H3. Rh2O3 forms a grey solid; insol. acids; reduced by H to Rh (Claus, l.c.). Fromy obtained it as lustrous, metal-like, crystais, somewhat volatile when heated in a stream of O, which decomposed ClAq giving HClAq and O.

HYDRATED RHODIUM SESQUIOXIDE. Rh2O3.3H2O (Rhodo-rhodic hydroxide, RhO3H3). A black gelatinous pp. formed by adding excess of KOHAq, and a little alcohol, to Na₃RhCl_cAq. Sl. sol. conc. HClAq (Claus, l.c.). (2) Rh₂O₃.5H₂O (Hydrated rhodo-rhodic hydroxide, RhO, H₂.H.O). Obtained by adding KOHAq to solution of IthCl, the latter being in excess, allowing to stand till the pp. is citron-yellow (the first rosc-red pp. contains the hydrate mixed with K_sRhCl_e), and washing with hot water (Claus, l.c.). The whole of the KOH cannot be removed from the pp. by washing. Sol. HClAq, HNO, Aq, H,SO, Aq, H,SO, Aq, and when freshly ppd. also in acction Also sol. conc. KOHAq, but reppd. on acid. dilution (Descotils, Gm.-K. 3, 1261). Said by Leidié (C. R. 107, 234) to be sol. in solution of alkali hydrogen oxalates. Solutions of this hydrate in acids yield the salts Rh,3X on evaporation; $X = 2NO_3$, C_2O_4 , SO_4 , SO_3 , &c.

RHODIUM DIOXIDE RhO, (Rhodi- or rhodic oxide). A brown solid; obtained by repeatedly

Insol. soids, or boiling KOHAq. Reduced to Rh by H at a high temperature (Claus, L.c.)

HYDRATED RHODIUM DIOXIDE RhO, 2H,O (Rhodic hydroxide, RhO, H4). Obtained by Claus (l.c.) by leading Cl into a solution of $Rh_2O_3.5H_2O$ in KOHAq till a dark-brown gelatinous pp. was formed, then adding pieces of KOH from time to time, and continuing the passage of CI until pp. became more compact, and green, and the solution became blue-violet. A greenish solid, sol. HClAq, forming a greenish-blue solution, which evolves Cl and becomes the deep-red colour of RhCl, solution (cf. Jörgensen, J. pr. [2] 27,

Rhodic acid and rhodates (?). blue-violet solution obtained by passing Cl into Rh₂O₃.5H₂O in KOHAq (supra) is fairly permanent, but after some time it ppts. a blue powder, gas is given off, and the liquid becomes colourless. When the blue powder is dried it becomes green RhO.2H2O. A blue pp. is also obtained by carefully neutralising the blue-violet solution by HNO, Aq; this powder, when moist, is sol. HClAq, with evolution of Cl; on heating, more Cl is evolved, and the liquid becomes the red colour of RhCl, solution. Claus (l.c.) regarded the blue-violet solution as containing potassium rhodate, and the blue pp. he looked on as rhodium trioxide or rhodic anhydride, RhO3.

Rhodium, salts of. But few salts are known obtained by replacing H of oxyacids by Rh; the chief are nitrate, nitrite, oxalates, phosphates, and sulphates; a few double salts are also known.

Rhodium, sulphides of. Rh and S combine when heated, probably forming RhS. Rh, S, is formed by ppn. from Rh salts.

RHODIUM MONOSULPHIDE RhS (Rhodous sulphide). Said by Berzelius to be formed by heating finely divided Rh in S vapour; also, accord ing to Vauquelin (A. Ch. 88, 167), by heating Am, RhCl_a with S. Fellenberg (P. 50, 63) obtained RhS by heating dry Rh, S_a in CO₂(?). A white-blue, lustrous solid; heated in air gives spongy Rh; heated in Cl forms RhCl, and S2Cl, (F., I.c.). RhS is insol. aqua regia, according to Debray (C. R. 97, 1333.) (v. also Gibbs, J. pr. 91, 171; Lecoq de Boisbaudran, C. R. 96, 152).

RIDDIOM SESQUISULPHDE Rh_S, (Rhodo-rhodic sulphide). Formed, by passing H,S into solution of a Rh salt, as a black pp. according to Leidić (C. R. 106, 1076, 1533) the pp. is Rh_S, 3H_S (p. Rhodium, hydrosulphide of, p. 404), which becomes Rh_S, by heating for some time with water at 100°, in a closed vessel or in N. Leidić (Lc.) obtained Rh_S, in black crystalling tablets by heating RhCl. to 360° in a stream line tablets, by heating RhCl₃ to 360° in a stream of H.S; according to L., this is the only method whereby pure Rh,S, can be prepared. Loses 8 p.c. S when heated in N to dull redness; all S expelled only in O-H flame (L., l.c.). Insol. alkali solutions; not acted on by HClAq, HNO,Aq, BrAq, or aqua regia (L., l.c.). Forms the double salt Rh₂S₃.3Na₂S, by adding excess of conc. Na₂SAq to Na₂RhC₁₈Aq; decomposed by water, stable in presence of excess of alkali M. M. P. M. sulphide (Leidié, l.c.).

RHODIUM - AMMONIUM COMPOUNDS. (Rhodammines. Ammoniacal rhodium bases.) When a solution of Rh in aqua regia is evafusing finely divided Rh with KOH and KNO, porated with excess of NH, Aq a compound Rh.Cl. 10NH, is obtained. By treating this body with moist Ag₂O and water in the cold Rh; Ol, O. H. 10NH, is formed; if heat is used, the product is Rh,O,H,.10NH, These compounds react as definite salts, which exchange their more negative radicles without losing Rh or NH. The classification of the rhodiumammonium compounds generally adopted is similar to that used for the Cr and Co compounds (v. vol. ii. pp. 158 and 222). In the following general formulæ M and X represent negative radicles, which may be the same or different

M₂.Rh₂.10NH₃.X₄ or N₄H₆(NH₄)₅(Rh₂M₂).X₄ Purpureo-rhodium series.

Rh. 10NH, X. 2H2O or N, Ha(NH4), Rh2. X6. 2H2O Roseo-rhodium series.

Rh2.12NH3.X6 or N4H4(NH1)8Rh2.X6 Luteo-rhodium series.

The Rh compounds were investigated by Berzelius (Lehrbuch, 5th ed., 3, 956); Vauquelin der Platinmetalle, Dorpat, 1854); and more recently by Jörgensen (J pr. [2] 27, 633; 34, 894; 44, 48).

L. PURPUREO-RHODIUM COMPOUNDS M.Rh. 10NH. X4. Changed to roseo salts, without loss of NH, by boiling with alkali solution. The two atoms of radicle represented by M., are not removed by the ordinary reagents for removing this radicle from salts.

Chloro-purpureo- series (Jörgensen, l.c.).

Chloropurpurcorhodium chloride Cl₂Rh₂10NH₃Cl₄. This salt is prepared by dissolving the alloy RhZn₂ in aqua regia, evaporating to dryness, treating the residue with water, filtering, adding excess NH₂Aq, evaporating to dryness at 100°, heating with dil. HClAq, and filtering while hot; the insoluble salt is washed with dil. HClAq, dissolved in boiling water, and the hot solution is filtered into HClAq (1:1 by volume); the purpureo-chloride which separates is washed with dilute HClAq, and then with alcohol. Small lustrous yellow rhombic crystals; isomorphous with chloropurpureo-cobalt chloride (v. Topsöe, J. pr. [2] 27, 433; Keferstein, A. Ch. 99, 275). S.G. 2.079 at 18°. S. 56 cold water, considerably more sol. hot water. Sol. without decomposition in hot cone. H2SO, also in boiling NaOHAq. Easily reduced to Rh, but not acted on by such exidisers as aqua regia or HClAq and KClO₃. Heated in CO₂ gives Rh, NH₄Cl, NH₃, and N; heated in H, gives Rh, NH₄Cl, and NH₃; heated in HCl gas, gives Rh and NH,Cl; heated in Cl gives RhCl, and NH,Cl. Reacts with various substances to exchange Cl, for equivalent quantities of other negative radicles. Combines with PtCl, to form the double salt Cl.Rh.10NH.Cl.2PtCl.
Chloropurpureorhodium hydroxide

Cl2.Rh2.10NH3. (OH)4. Known only in solution, which is obtained by rubbing the chlorochloride with a little water and moist Ag2O for a few minutes, and filtering. Reacts strongly alkaline; gives salts by neutralisation with various acids. After warming, the solution contains roseo-chloride, and hydroxide Rh₂.10NH₂.Cl₂(OH)₄, along with Rh₂.10NH₄.(OH)₆, and gives a pp. with AgNO, Aq.

The other salts of this series are the

 $M = Cl_2 \cdot Rh_2 \cdot 10NH_3$.

Bromopurpureo- series (Jörgensen, l.c.). Bromopurpureorhodium bromide

Br₁Rh₂10NH₂Br₄. Deep-yellow rhombic crystals; S.G. 2.65 at 17.5°; scarcely sol. water. Prepared similarly to the chlorochloride, using HBrAq in place of HClAq; also by dissolving the chlorochloride in 7 p.c. hot NaOHAq, digesting for about an hour at 100°, adding excess conc. HBrAq, washing the pp. which forms with dil. HBrAq and then with alcohol; also by saturating solution of roseo-hydroxide, Rh₂.10NH₃.(OH)₆, with dil. HBrAq and heating for some time at Forms a double salt with platinic bromide, Br., Rh., 10NH., Br., 2PtBr., The bromo-nitrate, Br., Rh., 10NH., (NO.)., and bromo-silicofluoride, Br., Rh., 10NH., 2SiF., have been isolated.

Iodopurpureo. series (Jörgensen, l.c.).
Iodopurpureorhodium iodide I.,Rh.,10NH,.I. Prepared by heating the roscohydroxide with excess of HIAq for some time; then transforming the impure product into iodochloride by washing with water, then with alcohol, rubbing repeatedly with dil. HClAq, dissolving in hot water, and filtering into dil. HClAq. The iodochloride is then dissolved in hot wafer and poured into KIAq; the ppd. iodo-iodide is crystallised from hot water. Reddish-yellow, rhombic crystals; S.G. 3:11 at 14:8°; very sl. sol. cold water. Forms a double salt with 2PtI. The other salts of this series are the iodo-chloride MCl₁, iodo-nitrate $M(NO_3)_1$, iodo-silicofluoride $M(SiF_0)_2$, and iodo-sulphate $M(SO_4)_2$.6aq. $M=I_2.Rh_2.10NH_3$.

Nitratopurpureo-series (Jörgensen, J. pr. [2] 31, 49). Nitratopurpureorhodium nitrate (NO₃)...Rh₂·10NH₂·(NO₃)₄. Formed by heating the roseonitrate Rh₂·10NH₃·(NO₃)₈ to 100°; also by adding an equal vol. cone. HNO₃Ag to an aqueous solution of the rosconitrate, and heating at 100°. Yellowish-white crystals; deflagrates when heated. The other salts of this series are nitrato-chloride MCl, and nitrato-dithionate M(S₂O₆)₂. 2aq. M = (NO₃)₂. Rh₂. 10NH₃.

Nitritopurpureo- series or Xantho-

series (Jörgensen, J. pr. [2] 31, 49). Nitritopurpurcorhodium nitrate

(NO₂)₂·Rh₂·10NH₂·(NO₃)₄ (Xanthorhodium nitrate). 5 g. chlorochloride are heated with 50 c.c. water and 30 c.c. NaOHAq (7 p.c.) till dissolved; after cooling, 10 g. crystallised NaNO, are added and then a slight excess of dil. HNO,Aq (1 acid: 2 water). The powder which separates after a time is washed with dil. HNO, Aq, and then with alcohol, and is crystallised from hot water. Octahedral crystals, isomorphous with corresponding Co salt. Insol. alcohol and dilute HNOsAq; sl. sol. cold water; easily sol. hot water and conc. HNO, Aq. No reaction with ordinary reagents for nitrites, e.g. KIAq, KMnO,Aq, &c. Conc. H2SO, does not evolve NO₂.

The other salts of this series are: xantho-

bromide MBr., xanthochloride MCl., xantho-dithionate M(S₂O₄), 2aq, oxalate M(C₂O₄), silicofluoride M(SiF₃), sulphates M(SO₄), and $M(SO_4)_3.8H_2SO_4$. $M = (NO_4)_2.Rh_2.10NH_2$.

11. ROSEORHODIUM COMPOUNDS

Rh., 10NH, X, 2H,O. All the atoms of the negative radicle in these salts react similarly; e.g. AgNO, Aq ppts. 6Cl from the chloride. Heated to 100° 2H2O is given off, and purpureo- salts remain. These compounds are generally formed by treating the chloropurpureo- compounds with hot alkali solutions. Many are prepared from the hydroxide by the action of acids (Claus, l.c.; Jörgensen, l.c.).

Roseorhodium hydroxide Rh, 10NH, (OH) Prepared by heating chloropurpureochloride with excess of moist Ag2O and water for some days, filtering from AgCl, and evaporating in vacuo. A yellow deliquescent solid, with strongly alkaline reaction; ppts. metallic hydroxides from salts; decomposes NH, salts, giving off NH, Neutralises acids, forming roseo- salts.

Roseorhodium bromide Rh., 10NH, Br g. 2H, O. Ppd. by adding cone. HBrAq to solution of the hydroxide; also by boiling chloropurpureo-chloride with NaOHAq, and then adding excess of conc. HBrAq. Pale-yellow crystals; changes to the purpurco- salt at 100°, or by crystallising from hot water. The other salts of this series MI₂(SO₄)₂; nitrate M(NO₃)₃, and the double salt M(NO₃)₂. PtOI₅; phosphate M(IIPO₄)₃,4aq, and the sodium pyrophosphate M(NaP₂O₃)₂.23aq; sulphate M(SO₄)₃.3aq, and the double salt M(SO,)2.PtCl.

III. LUTEORHODIUM COMPOUNDS Rh., 12NH ,. X .. These salts are very stable. Their colours are the same as those of corresponding roseo- salts. The chloride can be prepared by heating the chloropurpureochloride with conc. NH3Aq; most of the other salts are obtained from the chloride (Jörgensen, J. pr. [2] 44, 48, 63). The negative radicles are all acted on similarly by reagents.

Luteorhodium chloride Rh 12NH 3.Cl . Prepared by heating chloropurpurcochloride with c. 30 times its weight NH3Aq (25 p.c. NH3) for several days at 100°-102°, dissolving in hot water, and ppg. by cone. HClAq. S. c. 12 at 8°. Not and ppg. by conc. HClAq. S. C. 12 at 5. Av. Changed to chloropurpureochloride by digestion with HClAq at 100°. Forms the double salt Rh. 12NH., Cl. 3PtCl., Gaq. The other salts of this series described by Jörgensen are: bromide MBrs., nitrates M(NO₂), and M(NO₂), the head of the MCPO. phosphate M(PO₄), 28q and sodium luteopyrophosphate M(NaP₂O₇), 23aq, and sulphate M(SO₄), 5aq.

Rhodium-pyridine compounds. Compounds of Rh with pyridine, C,H,N, and negative radicles have been prepared by Jörgensen (J. pr. [2] 27, 433). The compounds examined contain 8C₅H₃N, and correspond with the chromtetrammonium series of ammoniacal compounds (vol. ii. p. 159), and with the octammine series of ammoniacal Co compounds (vol. ii. p. 225). The composition of these pyridine compounds is represented by the formula M,Rh,(C,H,N),X,; where M = Cl and X = Br, Cl, OH, NO, and SO. The salts resemble the NH, compounds generally. The chloride (X = Cl) is prepared similarly to chloropurpureorhodium chloride, using pyridine in place of ammonia; the other salts are prepared from the chloride by the action of acids. AgNO, Aq ppts. one-third of the halogen only from the chloride and bromide. M. M. P. M. RHODIZONIC ACID v. DI-OXY-DIQUINOYL.

RHEADINE $C_nH_nNO_a$. [232°]. S. (80 p.c. alcohol) 09. S. (ether) 08 at 18°. An alkaloid occurring in all parts of the red poppy Papaver Rhaas, and in the white seed capsules of the white poppy Papaver somniferum (Hesse, A. 140, 145; 149, 35; 153, 47). Small white prisms, nearly insol. water, alcohol, and ether. May be sublimed. Tasteless, and not poisonous. Its solution in very weak HCl is colourless, but in conc. HClAq and in H₂SO₄ it forms purple solutions, the base being partially decomposed. The colourless solution is ppd. by tannin and by HgCl2.

Salts.-B'2H2PtCl62aq: yellow amorphous pp.-B'HI 2aq: mass of minute prisms.

Rheagenine $C_{21}H_{21}NO_{6}$. [223°]. S. (80 p.c. alcohol) '07. S. (ether) '06. Formed by boiling rhoadine with dilute H.SO. Small crystals (from alcohol), sl. sol. ether, alcohol, and water, v. sol. dilute acids. Its alcoholic solution turns litmus blue. Cannot be sublimed. Not coloured by acids. Its salts taste bitter. - B'2H2PtCla-B'HI: short prisms, m. sol. hot water.

RIBONIC ACID C,H₁₀O₄ i.e. CH₂(OH).CH(OH).CH(OH).CH(OH).CH(OH).CO₂H.

Tetra-oxy-valeric acid. Formed by heating CH2(OH).CH(OH).CH(OH).CH(OH).CO2H, arabonic acid, with pyridine in a closed vessel at 130° (E. Fischer a. Piloty, B. 24, 4216). When set free from its salts it changes into the lactone .-

HgA'₂: needles.—CdA'₂: $(a|_{\rm p}=0.6^{\circ})$. Needles.

Lactons C₃H₃O₅. $(72^{\circ}-76^{\circ})$. $(a|_{\rm p}=-18^{\circ})$.

Colourless prisms, v. e. sol. water and alcohol, v. sl. sol. ether. Converted by heating with yridine and water at 135° into arabonic acid. HNO, yields tri-oxy-glutaric acid. Phenyl hydrazine forms C₂H₂O₂(N₂H₂Ph) [164°].

RIBOSE *C₃H₁O₃. Formed by reducing the lactone of ribonic acid with sodium-amalgam

(Fischer a. Piloty, B. 24, 4220). Colourless syrup. Yields a phenyl-hydrazide [155°] and a p-bromo-phenyl-hydrazide C₁₁H₁₅O₁N₂Br [165°].

RICINELAIDIC ACID C18H34O3. [58°]. Formed by the action of nitrous acid on ricinoleic Formed by the action of nitrous sons on action (Boudet, A. 4, 16; Playfair, A. 60, 322; Bouis, A. Ch. [3] 44, 82; Ulrich, Bl. [2] 9, 225). Got also by saponifying ricinelaidin. silky needles, v. sol. alcohol and ether. Reddens litmus. Yields n-heptoic acid on oxidation with HNO₃ (Krafft, B. 21, 2735). Alkaline KMnO₄ yields two tri-oxy-stearic acids [120°] and [116°] (Grüssner a. Hazura, M. 10, 196; Mangold, M. 13, 326). Forms oily $C_{18}H_{31}Br_2O_3$, converted by KOHAq in the cold into $C_{18}H_{33}BrO_3$, whence alcoholic potash forms an acid melting at 71°.

Salts.—BaA'; unctuous powder.—AgA'; white powder, sol. NH₄Aq.

Ethyl ether EtA'. [16°]. Crystalline.

Anide C₁₈H₃₃NO₂. [93°] (Rowney, Chem. Gas. 1855, 361).

Reference. BROMO-RIGINELAIDIC ACID.

BICINELAIDIN. [45°] (Bouis); [66°] (Boudet). Formed by the action of nitrous fumes on castor oil. Solid, v. sol. alcohol and ether. Split up by boiling KOHAq into glycerin and potassium ricinclaidate. Yields heptoic aldehyde (enanthol) on dry distillation (Bertagnini, A. 85, 282). Yields octyl alcohol and potassium sebacate on distillation with potash (Bouis). **RIGINIC ACID** C₁₈H₃₁O₃ i.e. C₁₇H₃₂(OH).CO₂H. [81°]. (252° at 15 mm.). Formed by distilling barium ricinoleate in vacuo (Krafft, B. 21, 2736). Plates (from dilute alcohol). Yields, on oxidation by HNO₃, n-heptoic acid and an acid [c. 103°] not volatile with steam. Converted by HCl into diricinic acid Steam. Converted by HCI into difficults acid C₁,H₂₂(OH).CO.O.C₁,H₂₂.CO.2H, triricinic acid C₁,H₂₂(OH).CO.O.C₁,H₂₂.CO.O.C₁,H₂₂.CO.2H, and polyricinic acids. Sulphuric acid forms these acids, as well as SO₃H.O.C₁,H₂₂.CO.2H, SO₃H.O.C₁,H₃₂.CO.2H, &c. II₂SO₃ acting on castor oil forms the compound

acids, constituting Turkey red oil. The polyricinic acids are converted by boiling KOHAq but not by Na CO, into ricinic acid. Hot water decomposes the polyricino-sulphuric acids into H.SO, and polyricinic acids (Juillard, Bl. [3] 6,

RICININE. An alkaloid occurring, according to Tuson (C. J. 17, 195; C. N. 22, 229; cf. Werner, C. N. 22, 203), in the seeds of the castor oil plant (Ricinus communis). Rectangular prisms or laminæ, insol. water, nearly insol. ether, sol. alcohol.

RICINISOLIC ACID v. TRI-OXY-STEARIC ACID.

RICINOLEÏC ACID C_{In}H_{ai}O₃ i.e. CH₂.[CH₂]₃.CH(OH).CH:CH[CH₂]₈.CO₂H (?) [17°]. Occurs as glycoride in castor oil (Bussy 108; Svanberg a. Kolmodin, J. pr. 45, 431; Bonis, A. Ch. [3] 44, 103; 48, 99; Petersen, A. 118, 69). Prepared by saponification of castor oil by KOH or HCl and purified by means of its Ca or Ba salt (Claus, B. 9, 1916; Krafft, B. 21, 2731). Crystalline mass, miscible with alcohol and ether. Its alcoholic solution is alkaline in reaction. Does not absorb oxygen from the air. Yields C₁₈H₃₃AcO₅. Yields polymerides when heated with water in closed vessels (Scheurer-Kestner, C. R. 113, 201).

Reactions .- 1. Oxidised by HNO3 to azelaic acid C_pH₁₀O₄, oxalic acid, and heptoic acid.— 2. Alkaline KMnO₄ forms two isomeric tri-oxystearic acids (Dieff, J. pr. [2] 39, 345; B. 20, 1211; Hazura a. Grüssner, M. 8, 475; Mangold, M. 13, 326).—2. Nitrous acid forms ricinelaidic acid.—3. Yields methyl hexyl ketone (173°) and an acid C₁,H₂,O₂ [81°] on distillation of the Ba salt.—4. The Na salt on distillation with NaOH salt.—4. The Na salt on distillation with NaOH yields methyl hexyl ketone, sec-octyl alcohol and sodium sebacate Na₂C₁₆H₁₆O₁,—5. Bromine forms oily C₁₆H₁₃Br₂O₂, converted by alcoholic potash into C₁₈H₁₃Br₂O₃, whence Br forms oily C₁₆H₂₃Br₂O₃, converted by alcoholic potash at 120° into ricinostearolic acid C₁₈H₂₂O₃, which combines with bromine forming unstable oily C₁₈H₂₂Br₄O₂.—6. PCl₃ forms C₁₈H₂₂Cl₂O.—7. HI and P give C₁₈H₂₃IO₂.

Salts.—BaA'₂: soft scales (from alcohol), sl. sol. water.—SrA'₂: small grains (from alcohol).—CaA'₂ (dried at 100°). [80°].—MgA'₂: slender needles, v. sol. alcohol.—PbA'₂. [100°]. Crystalline mass, v. sol. ether.—ZnA'₂.—AgA': ourdy pp.

ourdy pp.

Ethyl ether EtA'. Oil. Amide C, H3: CONH. Nodules [66°]. (from alcohol).

References .- Bromo- and Oxy- RICINOLSIC ACID.

RICINOLIC ACID v. TRI-OXY-STEARIC ACID. RICINOSTEAROLIO ACID C₁₈H₃₂O₃. [51°]. Formed by heating the dibromide of ricinoleic acid with alcoholic potash (Ulrich, Z. 1867, 547). Groups of needles (from alcohol), v. sol. ether. Volatile.-BaA'2: plates (from alcohol)

[135°].—AgA': granular pp. RICINOSTEAROXYLIC ACID [78°]. Formed by heating ricinostearolic acid with moist Ag₂O (Ulrich, Z. 1867, 550). Dendritic groups of needles (from alcohol), v. sol. ether.—BaA'₂.—AgA'; granular pp. decomposed by hot alcohol.

ROBININ C₂₅H₃₀O₁₆. [195°]. Occurs in the blossoms of the acacia (Robinia pseudacacia) (Zwenger a. Dronke, A. Suppl. 1, 257). Thin yellow needles (containing 51 aq). Neutral in reaction. Tasteless, sl. sol. cold water and alcohol, insol. ether. Sol. alkalis, forming yellow solutions. The ammoniacal solution turns brown in air. FeCl, gives a brown colour. Its alcoholic solution is ppd. by lead subacetate. Reduces hot Felling's solution. HNO, forms oxalic and pieric acids. Split up by boiling dilute acids into quercetin and a sugar.

ROCCELLIC ACID C₁, H₃₂O₄. [132°]. S. (boiling alcohol of S.G. 819) 55. Occurs in various species of Roccella (Hecren, S. J. 59, 346; Liebig, P. 21, 31; Schunck, A. 61, 64; Hesse, A. 117, 332). Four-sided prisms, insol. water, v. sol. alcohol and ether, sl. sol. warm benzene.

Sol. Na CO Aq and borax.

Salts.-BaA" (dried at 100°).-CaA" aq: amorphous pp. -Pb, A"2(OH), 2aq: white powder.

 $Anhydride C_1, H_{10}O_3$. Got by heating the acid above 220°. Oil, v. sol. hot alcohol and ether.

Anilide C₁, H₃₀O₂(NHPh)₂. [55°]. Got by heating the acid with aniline at 190°. Colourless laminæ (from alcohol), insol. water, NH,Aq, and HClAg

ROCCELLININ C18H16O. Occurs in Roccella tinctoria (Stenhouse, A. 68, 69). Silky needles (from alcohol), nearly insol. cold alcohol and other. Its solutions in alkalis are not coloured by air. Not decomposed by boiling KOHAq. Does not pp. metallic salts.

ROCHELLE SALTS, Potassium-sodium tar-

trate; v. TARTRATES.

ROSANILINE $C_{20}H_{21}N_{2}O$ *i.e.* ([4:1] $C_{20}H_{1}(NH_{2}))_{2}C(OH).C_{4}H_{3}M_{2}(NH_{2})[1:3:4].$ Tri-amido-di-phenyl-tolyl-carbinol. Formed by oxidation of a mixture of aniline, o-toluidine, and p-toluidine (Hofmann, J. pr. 77, 190; 87, 226; Pr. 12, 2; Mühlhäuser, D. P. J. 266, 455, 503, 547). SnCl., As.O., HNO., Hg(NO.), FcCl., and nitrobenzene may be used as oxidising agents. For the production of a red colouring matter it is essential that there should be present a base with methyl in the p-position to amidogen (p-toluidine, (1,3,4)-xylidine, or mes-idine), and also a base with H in the p- position to amidogen (e.g. aniline, o-toluidine, or (1,3,2)xylidine) (Rosenstiehl, C. R. 82, 415; 94, 1319; 95, 238; 98, 433; A. Ch. [6] 2, 360). When nitro-benzene is used as oxidising agent it appears to be itself reduced to benzene and nitrogen, and not to take part in the formation of rosaniline. Thus, when chloro-nitro-benzene, nitro-aniline, or di-nitro-benzene is used, a substituted rosaniline (e.g. chloro-rosaniline) is not formed (Lange, B. 18, 1918). Colourless needles or plates, obtained by ppg. a solution of one of its salts with NH₂Aq and recrystallising. Nearly insol. water, sl. sol. NH₂Aq, m. sol. alcohol, insol. ether. Turns red in air. Dyes silk and wool in acid, neutral, and even in slightly ammoniacal solutions.

Reactions.-1. Reduced by ammonium sulphide or powdered zinc to tri-amido-di-phenyltolyl-methane (leucaniline) (Hofmann, Pr. 12, 2) .- 2. Yields alkyl derivatives on heating with alkyl iodides and phenyl derivatives on heating a salt with aniline (Hofmann, Pr. 13, 9). Benzyl chloride, methyl iodide, and MeOII form $C_{20}H_{16}(C,H_{,)_4}N_3MeI$, crystallising in lustrous green needles (Hofmann, B. 6, 263).—3. The hydrochloride, heated with water at 235°, forms NH,Cl, phenol, red crystals of C20H20N2O2 [176°], and colourless crystals, which turn red in air and then crystallise from alcohol in red needles C₂₀H₁₉NO₃ (Liebermann, B. 5, 144; 6, 951).-4. The hydrochloride, heated with dilute HClAq at 240°, yields aniline and toluidine (L.).—
5. Water at 270° forms di-oxy-benzophenone, di-amido-phenyl-tolyl-ketone, oxy-amido phenyltolyl-ketone, phenol, and NH₃ (Liebermann, B. 6, 951; 11, 1435; 16, 1927).—6. Potassium cyanide added to rosaniline acctate in alcohol yields $C_{21}H_{20}N_4$, a white crystalline powder, sol. HClAq, and reppd. by NII₃Aq. 1t separates from alcohol in monoclinic crystals. It forms crystalline salts .- 7. A solution of a rosaniline salt is decolourised by SO2, and the solution is turned red, and afterwards violet, by aldehydes, and gradually deposits copper-coloured scales of alkylidene derivatives (Schiff, Bl. [2] 7, 518). C.H. CH: C.H., N., Thus cenanthol forms yields B'IIAsO, which yields B'HAsO, and B'H.PtCl_s.-8. *Œnanthol* reacts with rosaniline acetate in the cold, forming $(C_7H_{11})_3(C_{20}H_{16}N_3)_2$ (Schiff, $D\bar{l}$. [2] 5, 291) .- 9. By exhaustive chlorination it yields CCl, and per-chloro-benzene (Merz a. Weith, B. 16, 2876).—10. Boiling Ac₂O yields a tetra-acetyl derivative as a reddish am uphous powder. The same body is got by treating triacetyl-tri-amido-di-phenyl-tolyl-methane acetyl-tri-amido-di-phenyl-tolyl-methane with K.Cr., and HOAc (Renout, B. 16, 1303). A mono-acetyl derivative C20H18AcN3, got by heating rosaniline hydrochloride with acetamide, is reddish brown and yields dark-blue B'HCl with metallic lustre (Beckerhinn, J. 1870, 768).-11. May be sulphonated by H.SO, containing SO, at 130° (Schoop, Chem. Zeit. 11, 572).—12. By diazotisation followed by reduction with tin and HCl in the cold it is converted into 'roshydrazide,' the nydrochloride of which forms green crystals, and dyes cotton brownish-red (Ziegler, B. 20, 1557). -13. Br forms a tetra-bromo-rosaniline (?) crystallising from benzene in prisms (Caro a. Graebe, A. 179, 203).—14. Aldehyde forms a blue product which is converted by Na₂S₂O, into aldehyde green C₂₂H₂₇N₃S₂O, an amorphous green mass, sol. alcohol and ppd. by ether (Cherpin; Usebe, J. pr. 92, 337; Hof-

mann, B. 8, 761; Gattermann, B. 22, 227).

Salts.—These are derived from the anhydrous base C,H,N:C(C,H,NH_2),—C,H,,N,HCl.

Red crystals with green lustre. Insol. ether, sl. sol. water, m. sol. alcohol. Its solution in water or alcohol is crimson. Dyes wool and silk magenta. The absorption-spectrum has been studied by Hartley (C. J. 51, 169) .- C, H, N. 3HCl. Ppd. by conc. HClAq. Yellowish-brown needles. more sol. alcohol and water than B"HCl .-Decomposed by much water, forming B"HCl.-C₂₀H₁₉N₃4HCl or (C,H₆NH₃Cl).CCl(C,H₄NH₃Cl). Got by passing dry HCl into rosaniline powder (Rosenstiehl, Bl. [3] 9, 122). Reddish-brown and hygroscopic, forming a magenta solution. Fumes in air, giving off HCl. After keeping it is not completely soluble. - C20H19N34HBr. Resembles the preceding salt.—C₂₀H₁₉N₃HOAc. Large crystals with green metallic lustre; v. sol. water tals with green metallic lustre; v. sol. water and alcohol. $-(C_{20}H_{19}N_3)H_*PtCl_9$. Amorphous. $-(C_{20}H_{19}N_3)H_*PtCl_9$. $-C_{20}H_{19}N_3HBr$. Sl. sol. water. $-C_{20}H_{19}N_3HH$. Green needles, v. sol. water. $-C_{20}H_{19}N_3HNO_3$: small crystals. $-(C_{20}H_{19}N_3)H_2SO_1$ (dried at 130°). Crystals with green lustre. Does not form an alum with Al_(SO,)3 (Wood, C. N.38,1).-C20H1,0N3C,H3N3O,0 Red needles, very slightly sol. water. — $(C_{20}\Pi_{19}N_3)_2\Pi_2C_2O_4$ aq. — Tannate: ppd. by adding tannin to an aqueous solution of a salt of rosaniline. Red mass, insol. water, sol. alcohol and HOAc (E. Kopp, J. 1862, 694) .-Aurinate: Got by heating equivalent quantities of resamiline and aurin with alcohol (Dale a. Schorlemmer, C. J. 43, 186). Hexagonal crystals with green lustre (Dyson, C. J. 43, 471). More sol. alcohol than either constituent. Dyes silk magenta.—Phenate C₂₀H₁₂N₂C₃H₄O. Got by heating rosaniline with phenol, dissolving in alcohol, and ppg. with water (Dyson, C. J. 43.

Para-rosaniline C₁₀H₁₀N₃O i.e. ([1:4]C₀H₄(NH₂))₃COH. Tri-amido-tri-phenyl-carbinol.

Formation. - 1. From tri-nitro-tri-phenylmethane by exidation by CrO₃ and HOAs followed by reduction of the resulting tri-nitro-triphenyl-carbinol with zinc-dust and HOAc (E. a. O. Fischer, B, 11, 195, 473, 612, 1079, 1598; A. 194, 242) .- 2. By heating a mixture of aniline and p-toluidine with arsenic acid (Rosenstiehl, A. Ch. [5] 8, 192); formed therefore in the preparation of resamiline (Graebe, B. 12, 2241).-3. By heating p-nitro-di-amido-tri-phenyl-methane with FeCl₂ at 170° (O. Fischer, B. 15, 678).—4. By heating p-nitro-benzylidene bromide with aniline (Zimmermann a. Müller, B. 17, 2936). 5. Hy heating aurin with NH, Aq at 180° (Dale a. Schorlemmer, B. 10, 1016).-6. By heating di-amido-di-phenyl-methane (from aniline and formic aldehyde) with aniline, aniline hydrochloride, and nitro-benzene or arsenic acid.

Properties. — Crystallino plates. Nearly colourless; sl. sol. water; absorbs CO₂ from air. Its solution in conc. HClAq is coloured grassgreen by a crystal of KClO₂.

Reactions.—1. Yields o-toluidine and diamido-benzophenone [237°] on boiling with HClAq for a long time (Wienelhaus, B. 19, 110). 2. HIAq at 190° forms aniline and p-toluidine 3. Nitrous acid forms the tri-diazo-derivative, which on boiling is converted into aurin.—4. Reduced by sinc-dust and HClAq to tri-amido-triphenyl-methane.—5. KCy added to its hydrochloride in presence of alcohol forms 'hydrochloride in presence of alcohol forms 'hydro-

eyanpararosaniline ' C, H,, N, HCN, crystallising from hot alcohol in colourless prisms, forming sonverted by conc. HClAq (55 g.), water (55 g.), and aldehyde (22 g.) in the cold into aldehyde blue, a dark-blue hygroscopic powder, ppd. by adding NaCl to the product after dilution with water (Gattermann, B. 22, 227). Aldehyde blue yields, on distillation, a solid base C10H, N.

Salt .- C10 H18 N3 Cl. S. . 24 at 90

Tri-methyl-rosaniline v. TRI-METHYL-TRI-AMIDO-DI-PHENYL-TOLYL-CARBINOL.

Hexa-methyl-pararosaniline v. Hexa-methyl-TRI-AMIDO-TRI-PHENYL-CARBINOL.

Phenyl-resamilines v. HEXA-PHENYL-TRI-AMIDO-TRI-PHENYL-CARBINOL and TRI-PHENYL-TRI-

AMIDO-DI-PHENYL-TOLYL-CARBINOL.

ROSEINE. A name for salts of Rosaniline. **ROSEMARY OIL.** S.G. 15.905. a = +42'to +9° 48' in 100 mm. (Schimmel, Ph. [3] 21, 940; 22, 328). Obtained by steam-distillation from Rosmarinus officinalis (Kane, Trans. Irish Acad. 18, 135; Lallemand, A. 114, 197; A. Ch. [3] 57, 404; Gladstone, J. 1863, 549; Montgolfier, Bl. 1816, 18; Bruylants, J. Ph. [4] 29, 508). Contains a terpene (165°), dextrorotatory camphor, borneol, and cineol C₁₀H₁₈O (176°-179°) (Weber, A. 238, 89). The cineol forms a hydrochloride (C₁₀H₁₀O) HCl, a tetra-bromide [124°], and the iodide C₁₀H₁₀I₂ [79°].

ROSE OIL. Obtained by steam-distillation from rose leaves. Contains a stearoptene $C_{16}H_{31}$ [34°] (365°) which is not attacked by chromic acid mixture and appears to be a paraffin (Maracia mixture and appears to be a parainn (Markownikoff, B. 23, 3191; J. pr. [2] 48, 311; cf. Blanchet, A. 7, 154; Gladstone a. Dale, C. J. 17, 1; Salkülünski, N. R. P. 24, 129; Bauer, D. P. J. 204, 253; Flückiger, Z. [2] 6, 126; Panajotoff, B. 24, 2700; Eckart, B. 24, 4205). Rose oil also contains rhodinol (q.v.). Bulgarian oil of roses contains roseol C10H20O (225° cor.), which is oxidised by KMn₀, to C₁₀H₁₀(OH)₁ (240°) S.G. ⁹₆ 1·0445; ²⁰₁ 1·0343; and is reduced by HI to C₁₀H₂₂ (159°) S.G. ⁹₆ ·7700; ²⁰₇₅₅₄ (Ladenburg, J. pr. [2] 48, 293).

ROSEOCOBALT SALTS v. COBALTAMINES,

vol. ii. p. 226.

ROSEOCHROMIUM SALTS v. CHROM-AMMO-NIUM SALTS, vol. ii. p. 160.

ROSEORHODIUM SALTS v. RHODIUM-AMMO-

NIOM COMPOUNDS, this vol. p. 407.

ROSEWOOD OIL. The oil got by steamdistillation from the wood of Convolvulus scoparius contains a terpene C₁₀H₁₆ (249°) (Gladstone a. Dale). Rosewood also contains a black resin $C_2H_{2i}O_6$ [95°] S.G. 15 1.266, which is insol.

water, sol. alcohol, and gives a blood-red colour with H.SO. (Terreil a. Wolff, Bl. [2] 33, 435).

ROSINDOLES. Red colouring matters, greatly resembling rosaniline, formed by heating indoles with BzCl, and by oxidation of benzylidene derivatives of indoles (E. Fischer a. Wagner, B. 20, 815). Thus methyl-ketole yields dimethyl rosindole, C₂₅H₂₀N₂, which may possibly be CPh(C,H,NH) NC,H.

 $\begin{array}{lll} \textbf{ROSINDONE} & \textbf{C_6H_4} \diagdown \begin{matrix} \textbf{CO.CH:C.NPh} \end{matrix} \begin{matrix} \textbf{C_6H_4} \\ \end{matrix} \\ \end{array}$ Rosindulone. [262°]. Formed by heating rosin-

duline with conc. HClAq at 170° under pressure (Fischer a. Hopp, A. 256, 238; 262, 244).

Formed also from oxy-naphthoquinone and phenyl-o-phenylene-diamine (Kehrmann, J. pr. [2] 43, 269; B. 24, 586). Red hexagonal tables, insol. hot water, m. sol. boiling alcohol, forming a scarlet solution with brick-red fluorescence. Reduced to naphthophenazine by distilling in a current of H over zinc-dust. Converted by p-toluidine at 130° into p-tolyl-rosinduline. Oxidised by CrO, to rosindonic acid C₂₂H₁₁N₂O₃, which crystallises in colourless needles, sl. sol. alcohol, insol. water, v. sol. ether.

ROSINDULINE C₂₂H₁₂N₃ i.e.

CH

CH

CH

 $C_eH_4 < \overline{C(NH).CH:C.NPh} > C_eH_4.$ Г199°7. Formed by heating benzene- azo- (a)-naphthylamine with aniline and alcohol at 1650 under pressure (Fischer a. Hepp, A. 256, 236). Formed also by heating phenyl-o-phenylene-diamine with oxy-naphthoquinone imide, HOAc, and alcohol at 100 (Kehrmann, J. pr. [2] 43, 269; B. 24, 587). Reddish-brown plates, v. sol. alcohol and ether, insol. water. Conc. H2SO, forms a green solution, becoming red on dilution. The alcoholic solutions exhibit reddish-yellow fluor-

escence.—B'HCl 3 aq: red needles.

Rosinduline. This name has also been given to the phenyl derivative of the preceding body

(v. vol. iii. p. 9).
ROSOLIC ACID v. TRI-OXY-DI-PHENYL-TOLYL-CARBINOL and TRI-OXY-TRI-PHENYL-CARBINOL.

ROTTLERIN C₁₁H₁₀O₂? [200°]. A yellow substance occurring in the fruit of Rottlera substance occurring in the fluit of Institution in the fluit of Institution in India (Anderson, N. Ed. P. J. [2] 1, 300; Jawein, B. 20, 182). It is identical with Mallotoxin (q. v.).

RUBAZONIC ACID C₂₀H₁,N₅O₂. Formed by oxidation of oxy-amido-phenyl-methyl-pyrazole (Knorr, A. 238, 137). Got also by boiling pyrazole-blue with NH,Aq. Prepared from the phenyl-hydrazide of oxy-phenyl-methyl-pyrazole by reduction with zinc dust and HOAc, followed by oxidation with FeCl, (Buchka a. Sprague, B. 22, 2551). Insol. water and dilute acids, v. sol. ether and benzene. Its solutions in alkalis are deep violet, but on boiling become yellow.

RUBERYTHRIC ACID C₁₈H₂₀O₁₄ i.e. C₁₄H₆O₂(OH).O.C₁₂H₁₄O₃(OH), Rubianic acid. [260°]. Obtained from madder-root by extracting with boiling absolute alcohol (Rochleder, A. 80, 321; 82, 205; Schunck, A. 66, 176; Liebermann a. Bergami, B. 20, 2241). Lemon-yellow needles, v. sol. hot water, v. sl. sol. cloohol, insol. ether. Its alcoholic solution is yellow. Alkalis form blood-red solutions. It does not ferment with yeast. Boiling dilute acids split it up into alizarin and sugar. Ac2O and NaOAc yield allizarin and sugar. Ac₂U and NaUAC yield $C_{2a}H_{2a}Ac_{a}O_{14}$, crystallising in yellow needles $[230^{\circ}] \cdot C_{2a}H_{2}KO_{14}$.—BaA'₂aq. **RUBIAN** $C_{2a}H_{34}O_{15}$. A glucoside in madder root, split up by acids, alkalis, or the madder-

ferment (erythrozym) into glucose, alizarin, and other bodies (Schunck, P. M. [4] 12, 200, 270; J. pr. 59, 465). Amorphous resin, v. sol. water, m. sol. alcohol, insol. ether. Its solutions are very bitter. Yields ruberythric acid on treatment with baryta. It is probably a mixture of ruberythric acid and other bodies.

RUBIANIC ACID v. RUBERYTHRIG ACID. RUBIDINE. A general name for homologues of pyridine of the formula OHH, N, e.g. DI-METHYL-ISOBUTYL-PYRIDINE.

Bubidine C, H, N. (280°). S.G. 22 1.017. Occurs in coal tar (Thenius, Rep. Chim. app. 4, 181). Liquid, sl. sol. water, miscible with alcohol and ether. Its salts redden in the air. Bleaching-powder gives a red colour. Colours acidified fir-wood red. — B'₂H₂PtCl₄: reddish

crystalline powder.
RUBIDIUM. Rb. At. w. 85.2. Mol. w. unknown. Melts at c. 38.5° (Bunsen, A. 125, 367). S.G. c. 1.52 (B., I.c.). Refraction-equivalent 12.1 (Gladstone, Pr. 18, 49); 11.6 (Kannonikoff, J. R. 1884 [1] 119). Chief lines in emission-spectrum are two in the red, Rb, and Rb,, 7800 and 6297; and two in the violet, Rb, and Rb, 4216 and 4206 (Kirchoff a. Bunsen, P. 113, 337; Lecoq de Boisbaudran, Spectres lumineux [1874] 46; v. also B. A. 1884. 438). Beketoff (J. R. 1888. 363) gives $[Rb^2, O] = 94,900$.

Occurrence.-Never free. Salts are widely distributed, but in very small quantities, along with salts of Cs, and frequently also salts of Li K, and Na. Many lepidolites contain Rb salts amounting to c. 24 p.c. Rb (K. a. B., P. 113, 337; 119, 1; Grandeau, A. Ch. [3] 67, 155; Allen, Am. S. [2] 34, 367). Traces of Rb salts have been found in specimens of orthoclase (Erdmann, J. pr. 86, 377, 448; Laspeyres, A. 134, 349; petalite (Grandeau, l.c.); micas (Schrötter, J. pr. 85, 458); basalt (Engelbach, A. 135, 126); carnallite (Erdmann, l.c.); in alum obtained on the island of Volcano (Cossa, Acc. dei Lincci, 11, 9); saltpetre (Dieulafait, C. R. 98, 1545). Small quantities of Rb salts, varying from c. .0002 to c. .03 g. RbCl per litre, occur in mineral springs (v. Bunsen, A. 122, 347: Grandeau, A. Ch. [3] 67, 155; Schrötter, J. pr. 85, 458; Redtenbacher, J. pr. 85, 458; Böttger, J. pr. 89, 378). Traces of Rb salts have been found in sea water (Sonstadt, C. N. 22, 25, 44); in fumaroles giving out boric acid (Hofmann, J. C. T. 1863. 354); in coffee, tea, cocoa, and tobacco (Grandeau, l.c.); in the ashes of beetroot (G., l.c.; Lefèvre, C. R. 55, 430); in the ashes of various plants (von Than, A. Suppl. 2, 81); in normal human urine (Schiaparelli a. Peroni, G. 10, 390). According to Lockyer a well-marked Rb line occurs in the solar spectrum (Pr. 27, 279).

Historical.-In 1860 Bunsen applied the method of spectroscopic analysis, then being worked out by him along with Kirchoff, to the examination of the residue obtained by evaporating very large quantities of the water from a mineral spring at Dürkheim. Two red lines appeared which were not known to belong to any element. By further investigation Bunsen separated the chloride of the element, and on electrolysing the molten chloride he obtained metallic globules, which rose to the surface and took fire. By strongly heating an intimate mixture of the carbonate of the new element with finely divided charcoal and distilling into a re-ceiver under rock-oil, Bunsen obtained the metal in some quantity. The name rubidium was given because of the characteristic lines in the red part of the spectrum (ruber = dark red) (v. Bunsen, A. 113, 337; 122, 347).

Formation. -1. By distilling the mixture of Rb.CO. and C obtained by carbonising Rb.H tartrate (Bunsen, l.c.; Setterberg, A.211, 100).-2. By distilling a mixture of RbOH and Al (Beke-

toff. J. R. 1888, 363).-8. By passing a strong electric current through molten RbCl, the positive electrode being graphite, and the negative an iron wire, globules of Rb rise to the surface, and there take fire. If the negative electrode is surrounded with H (v. Lithium, vol. iii. p. 148), a smalt-blue substance is formed, which dissolves in water with formation of RbOH and H; this blue solid is probably a lower chloride than RbCl, perhaps Rb,Cl (Bunsen, l.c.).

Preparation .- The saline residues from the manufacture of lithium compounds from Saxon lepidolite (at Struve's works in Leipzig) were found by Bunsen (l.c.), Heintz (J. pr. 87, 310), and Erdmann (J. pr. 86, 294) to be rich in Rb salts. The specimen examined by Bunsen contained 19.75 p.c. RbCl. Cossa (B. 11, 811) recommended the natural alum from the island of Volcano as a good raw material for preparing

Rb salts.

1. Bunsen's method (A. 122, 351) for separating Rb is based on the different solubilities in water of the platinochlorides of K. Rb. and Cs: these solubilities at 17° are in the ratio of 15:2:1. One kilo. of the saline residue from the preparation of Li compounds from Saxon lepidolite is dissolved in 2.5 kilos, water, and ppd., when cold, by 30 g. Pt in aqua regia. After settling the liquid is drawn off, and the pp. is boiled 25 times in succession with small quantities of water (1.5 kilos, in all), each portion being poured into the liquid which was drawn off from the pp. by the PtCl4. The 4 kilos. of liquid and washings are evaporated to 2.5 kilos. While this evaporation is proceeding, the washed platinochloride pp. is dried at 100°, heated nearly to redness in a stream of H until a mixture of Pt with RbCl, and perhaps a little CsCl, remains (if the solid melts reduction is incomplete); and the RbCl is dissolved out in hot water. The Pt which remains is dissolved in aqua regia, and added to the liquid which has been evaporated. The pp. is washed with small quantities of water as before, dried, and reduced in H, the supernatant liquid and washings being evaporated. The reduced Pt is dissolved and added to the liquid, and so on. These processes are repeated seven or eight times. From 1 kilo. material Bunsen obtained .125 kilo. RbCl, containing 3-4 p.c. KCl and a little CsCl. To separate KCl, the approximately pure RbCl is dissolved in water (36 g. in 1 litre), heated to boiling, and a boiling solution of PtCl, (30 g. Pt in aqua regia, diluted to 1 litre) is added; the pp. is washed repeatedly with water at 40°-50°, then dried, and reduced in H; the RbCl is dissolved in water, and the Pt in aqua regia, and these processes are repeated until the RbCl shows no trace of the red lines of K in the spectroscope. Finally, Bunsen separated CaCl by transforming the chlorides into carbonates, and treating the powdered salts with boiling absolute alcohol until the insoluble RbCl ceased to show the blue lines of Cs in the spectroscope (RbCl is insoluble, while CsCl dissolves, in absolute alcohol). This process has been modified by Heintz (J. pr. 87, 310), Grandeau (A. Ch. [8] 67, 155), Piccard (J. pr. 86, 449), Böttger (J. pr. 89, 878), Schrötter (J. pr. 85, 458), de Boisbaudran (Bl. [2] 17, 551), and others.

2. Redtenbacher's method (J. pr. 95, 148) is

based on the different solubilities of the alums of K, Rb, and Cs; the solubilities in water, at 17°, are as 22:4:1. The method has been modi-17°, are as 22'4:1. The method has been mounded by Stolba (J. pr. 99, 49), Godefiroy (A. 181, 176), Petersen (D. P. J. 224, 176), Cossa (B. 11, 811), Setterberg (A. 211, 100), Robinson a. Hutchins (C. N. 49, 253). The mother-liquor from which Li₂CO₃ has been separated by Schrötter's method (vol. iii. p. 149) is evaporated with 18°CO Ac with addition of Al (SO). with H₂SO₄Aq, with addition of Al₂(SO₄)₃, whereby Rb and Cs alums are obtained mixed with K alum. Or lepidolite may be decomposed by heating with H,SO, and CaF, the residue boiled with five or six volumes water, KOH added equal to 5 p.c. of the quantity of lepidolite used, the whole boiled with water, and filtered hot, when the alums crystallise out on cooling (Stolba, I.c.). The alums are dissolved in half their weight of boiling water, half as much cold water is added, and after stirring the whole is let cool to 45°, when almost all the Rb and Cs alums separate, leaving much K alum in solution. The solution in water, and cooling, are repeated, tomperature being allowed to fall to 40°; the alum which separates is dissolved in water equal to half the weight of the original quantity of mixed alums, boiled for some time, and allowed to cool to 60° while being stirred. The crystals which separate are almost pure Cs alum; the mother-liquor, when evaporated, yields almost pure Rb alum.

To prepare the metal, RbCl or Rb alum can be transformed into RbOII, and Rb prepared therefrom; or the RbOH may be dissolved in the proper quantity of tartaric acid to form RbH tartrate, which may then be charred, and Rb obtained from the mixture of Rb₂CO₂ and C

so formed.

To prepare RbOH, the RbCl is converted into Rb₂SO₄ by H₂SO₄Aq, the Rb₂SO₄ is dissolved in water, boiled, BaOAq is added, the liquid being kept boiling. BaSO, is removed by decantation, and the liquid is evaporated to dryness in a silver dish as quickly as possible. RbOH is obtained from Rb alum by dissolving in hot water, ppg. Al₂O₃ by slight excess of NH,Aq, filtering hot, evaporating to dryness in a Pt dish, strongly heating till (NH4)2SO4 is removed, and then proceeding to decompose the Rb₂SO₄ by BaOAq as already described. RbOH is mixed with Al clippings in the ratio 2RbOH:Al (=1 part Al to 7.5 parts RbOH), and the mixture is heated to full redness in a furnace, in an iron cylinder, connected by an iron tube with a glass receiver. The Rb distils over, and appears like Hg in the receiver. As H is given off, the Rb is surrounded by a non-oxidising atmosphere (ARbOH + 2Al = Rb,O.Al,O. + 2Rb + 2H.). From 28 to 33 p.c. of the Rb in RbOH is obtained (Beketoff, J. R. 1888. 363; abstracts in C. J. 58, 108, and B. 21, Ref. 424). For a description of the method of preparing Rb from Rb₂CO₃ and C v. Bunsen (A. 125, 367) and Setterberg (A. 211, 100). An explosive compound similar to the compound of K and CO (this vol. p. 300) is liable to be formed.

For a method of separating Rb from Cs and K, based on the formation of double compounds of RbCl with SbCl₂, and with SnCl₄, v. Muthmann (B. 26, 1019 [1893]).

Properties .- A very lustrous, white metal,

with an extremely faint tinge of yellow. Soft as wax, even at -10° ; melts very easily (c. 38.5°). Lighter than water. Bunsen (A. 125. 367) made one determination of S.G., which gave 1.52, but the result is not final. Heated in absence of O, the metal distils below redness, forming a blue vapour. Rb dissolves in liquid NH₃ (Seeley, C. N. 23, 169). When exposed to air Rb is at once covered with a greyish-blue film, which is supposed to be a suboxide: much heat is produced, and the metal soon takes fire. Decomposes cold water very rapidly, with evolution of H, which takes fire. Rb is the most positive element next to Cs. It closely resembles K in its chemical relations (v. Alkalis, METALS of the, vol. i. p. 114). The at. w. of Rb has been determined (1) by determining Cl in RbCl by Bunsen (P. 113, 339; 115, 584 [1861]), Piccard (J. pr. 86, 454 [1862]), and Godeffroy (A. 181, 180 [1975]). (2) 189 [1875]); (2) by determining V.D. of RbCl and RbI at c. 1200° (Scott, Pr. E. 14, 410). The S.H. of Rb has not been determined; but from observations of the molecular heats of RbCl and Rb₂CO₃, and comparisons of these with those of the corresponding salts of metals that have normal atomic heats, it is probable that the atomic heat of Rb is c. 6.4, and, therefore, that the S.H. is c. 075. The atom of Rb is monovalent in the gaseous molecules RbCl and RbI.

Reactions and Combinations.—1. Rapidly oxidises in air; much heat is produced, and the metal ignites. Beketoff (J. R. 1888, 363) gives [Rb²,0] = 94,900.—2. Decomposes cold water, with rapid evolution of H and production of RbOHAq; Beketoff (Le.) gives [Rb,H²OAq] = 96,400, with formation of RbOHAq and H.—3. Burns in vapour of chlorine, bromine, iodine, sulphur, and arsenie, forming compounds with

those elements (Bunsen, l.c.).

Detection and Estimation. — Phosphomolybdic acid gives a yellow pp. insol. acids (Debray, Bl. [2] 5, 404). Silicotungstic acid (SiW₁,0₂,H₃,xH₄,0) ppts. Rb salts, but not salts of K (Godeffroy, B. 9, 1365). As Cs salts are ppd. by SbCl₃ in conc. HClAq, added to solutions containing conc. HCl (as 6CsCl.SbCl₃), while Rb salts give no pp., Rb can be separated from Cs salts by addition of HClAq and SbCl₃ in HClAq (G., B. 8, 9). Rb is best detected by the spectroscope. The most characteristic lines are in the blue-violet, Rb₂(λ = 4206), and Rb₃(λ = 4216): '0002 mgm RbCl can be detected (Bunsen, l.c.). Rb is determined in the form of RbCl. For the separation of Rb from K, and estimation of the Rb, v. Bunsen (l.c.). Bunsen determined RbCl in presence of CsCl by finding the sum of the two chlorides, then estimating the total Cl, and calculating the quantity of each salt.

Rubidium, amalgam of. When conc. RbClAq is electrolysed, using Hg as negative electrode, a solid, white, lustrous, crystalline amalgam is formed. Decomposes cold water rapidly; becomes oxidised superficially in air, and then deliquesces with formation of RbOH. Is electropositive to K amalgam (Bunsen, A. 122, 847).

347). Rubidium, bromide of. RbBr. Formula probably molecular, from analogy of RbCl and RbI. Formed by burning Rb in Br. Also by saturating HBrAq with Rb₂CO₂, and evaporating.

White, lustrous, regular octahedra. S. 98 at 5°, | 104'8 at 16° (Reissig, A. 127, 38). Melts at c. 683° (Carnelley, C. J. 33, 279). Combines with IBr, to form RbBr.IBr; and with Br to form RbBr.Br; (Wells a. Wheeler, Am. S. [3] 43, 475).

Rubidium, chloride of, RbCl. Mol. w.

20-57. V.D. at 1200°-1500° 69-7 (Scott, Pr. E. 14, 410). Melts at c. 710° (Carnelley, C. J. 33, 279). By burning Rb in Cl. Also by saturating HClAq with Rb.CO₃, evaporating, and crystal-lising from water. Also by reducing Rb.PtCl₆ in H, and dissolving out RbCl in water (cf. Preparation, p. 411). White, lustrous, cubical crystals; unchanged in air; decrepitates when heated, and then melts, and volatilises at a very high temperature. S. 76.38 at 1°, 82.89 at 7°; sol. alcohol (Bunsen, l.c.). Molten RbCl is a good conductor of electricity (Hampe, Chem. Zeitung, 1887. No. 54). Double compounds: RbCl combines with many metallic chlorides; some at any rate of the products, e.g. the platingand platini chlorides Rb2PtCl, and Rb2PtCl6, are best regarded as Rb salts of acids containing metals and Cl. The following compounds have been prepared: M=RbCl. - 6M.SbCl3 (1); 3M.2SbCl₃ (6); 6M.BiCl₃ (1); 2M.CdCl₂, M.CdCl₂,αH₂O (1); 2M.CrCl₃,aq (2); 2M.CuCl₂ (1); M.GuGl₂æH₂O(1); 2M.GrOl₂aq (2); 2M.GuGl₂(1); M.AuGl₃ (3); 3M.FeGl₃aq (1); 2M.FeGl₃aq (2); 2M.HgGl₂ 2aq. HgGl₂ 2aq. M.2HgGl₃ M.2HgGl₄ M.4HgGl₂(1); 2M.NiGl₂ (1); 2M.PtGl₄ (4); 2M.PtGl₄ (5); 3M.TiGl₃ (2); 2M.SnGl₄ (1); 2M.ZnGl₂ (1). Reference to the above (1) Galacters B. 2

References to above.—(1) Godefiroy, B. 8, 9; (2) Neumann, A. 244, 329; (3) Rosenbladt, B. 19, 2535; (4) Nilson, Bl. [2] 27, 210; (5) Bunsen, A. 122, 347; (6) Muthmann, B. 26, 1010, 145.

1019, 1425.

RbCl also combines with IBr to form RbCl.IBr; with ICl, to form RbCl.ICl; with BrCl, to form RbCl.BrCl; and with Br to form

RbCl.Br₂ (Wells a. Wheeler, Am. S. [3] 43, 475).
Rubidium, cyanide of. Setterberg (A. 211, 100) probably obtained a cyanide of Rb by passing dry HCN into an alcoholic solution of RbOH. Reissig (A. 127, 33) failed to obtain the sult free from products of decomposition.

Rubidium, ferrocyanide of; v. vol. ii. p. 335. Rubidium, fluoride of, RbF. Formula probably molecular, from analogy of RbCl and RbI. S.G. 3.202 at 16.5° (Clarke, Am. S. [3] 13, 293). Melts at c. 753° (Carnelley, C. J. 33, 279). Forms a double compound with uranyl fluoride, 4RbF.UO₂F₂-6aq (Ditte, C. R.

91, 166). Rubidium, hydroxide of, RbOH. A white, brittle solid, with slight greyish tinge; very alkaline and caustic; easily sol. water, with production of much heat; sol. alcohol. Formed by decomposing HO by Rb; also by boiling Rb, SO, Aq till air is driven out, adding BaOAq gradually, keeping the liquid boiling till BaSO, ceases to be formed, decanting from BaSO,, which separates out rapidly, and evaporating in a silver dish. Melts below redness; is not decomposed by heating. When molten attacks Pt. Beketoff (J. R. 1888, 363) gives [Rb,O,H] = 164,800; [Rb²O,H²O] = 69,900.

Rubidium, iodide of, RbI. Mol. w. 211.53. V.D. 110.8 at 1200°-1500° (Scott, Pr. E. 14, 410). Melts at c. 642° (Carnelley, C. J. 33, 279). Lustrous, white, regular octahedra; unchanged

in air. S. 187.5 at 6.9°, 152 at 17.4°. Formed by saturating HIAq with Rb, CO,, evaporating, and crystallising from water. Also by heating Rb in I vapour (Reissig, A. 127, 33). RbF combines with I to form RbI.I. (Wells a. Wheeler. Am. S. [3] 43, 475).

Rubidium, oxides of. No oxide of Rb has been isolated. Rb burns in air, possibly with formation of an oxide and peroxide similar to K2O and K2O4. The greyish-blue film which is formed on the surface of the metal when exposed to the air is perhaps a suboxide. According to Beketoff (J. R. 1888, 363), the thermal value of [Rb2,O] is 94,900.

Rubidium, salts of. The principal salts formed by replacing H of oxyacids by Rb are borate, carbonates, chlorate and perchlorate, chromate and dichromate, molybdate, nitrate, oxalate, silicotungstate, sulphate, and thio-sulphate (v. Carbonates, Nitrates, &c.).

Rubidium, silicofluoride of. Rb,SiF, White, regular crystals. S.G. 3°338 at 20°, S.c. 16 at 20°, 1°35 at 100°. By ppg. hot Rb alum solution by CuSiF₆ (Stolba, J. pr. 102, 1). M. M. P. M.

RUBIJERVINE v. JERVINE.

RUE OIL. The essential oil (c. 229°) obtained by distilling Ruta graveolens contains methyl ennyl ketone C11H22O (224°), a ketone $C_{12}H_{24}O$ (232°), and a small quantity of terpene (Gerhardt, C. R. 26, 225, 361; Cahours, C. R. (Gernardt, C. A. 26, 282, 507, Calcatal), 26, 262; Greville Williams, T. 1858 [1] 99; A. 107, 374; Hallwachs, A. 113, 108; Harbordt, A. 123, 293). By boiling oil of rue with nitric acid (S.G. 1:2) an acid (C.H., N.Q. may be obtained (Chiozza, A. 85, 225; Alexejeff, Z. 1865, 736). This acid is a heavy oil, forming KA' and NaA', crystallising from alcohol in greenishyellow tables (Limpach, A. 190, 298).

RUFICOCCIN v. CARMINIC ACID.
RUFIGALLIC ACID v. HEXA-OXY-ANTHRA-

OUINONE. RUFIN C21H20O8. A product of the action of heat on phlorizin (Mulder, Rev. Scientif. 3, 50; Stas, A. 50, 198). Dark-red resin, sol. alcohol, nearly insol. ether and water. Its alkaline solutions are red. Ac₂O forms C₂₁H₁₉AcO₈ (Schiff,

A. 156, 5). RUFIOPINE is TETRA-OXY-ANTHRAQUINONE. RUFOL v. DI-OXY-ANTHRACENE.

RUTHENIUM -

RUTHENAMMINES

AMMONIUM COMPOUNDS, p. 418.
RUTHENATES v. RUTHENIUM, SALTS OF
OXYACIDS OF, p. 417.
RUTHENITES v. RUTHENIUM, SALTS OF

OXYACIDS OF, p. 417. RUTHENIUM. At. w. 101.4. Mol. w. unknown. Melts at highest temperature attainable by O-H flame, which is above 2000° (Deville a. Debray, A. Ch. [3] 56, 385). S.G. 12-26 at 0° (crystallised) (D. a. D., C. R. 83, 928); older determinations varied from 8-6 to 11-4. Joly (C. R. 116, 430) gives S.G. of Ru melted in an electric furnace as 12.63 at 0° referred to water at 4°. S.H. 0611 from 0° to 100° (Bunsen, P. 141, 1). C.E. at 40° (linear) .00000963 (Fizeau, C. R. 68. 1125).

Occurrence.-In many platinum ores; Ru is a constant ingredient of osmiridium (vol. iii. p. 47), the quantity varying from 8 to 6 p.c. (v. Claus, A. 56, 257; 59, 234; Gibbs, Am. S. [2] 29, 427; 81, 68; 84, 841). Wöhler found Ru₂S, in laurite, a rare mineral occurring in Borneo and

in Oregon (J. pr. 98, 226).

In 1828 Osann (P. 13, 283; 14, 329; cf. 64, 197) thought he had discovered three new metals in the portion of a Pt ore insol. in aqua regia; to these metals he gave the names polin, pluranium, and ruthenium (from Ruthenia = Russia). In 1845 Claus (A. 56, 257; 59, 234; cf. 63, 359) examined the substance called ruthenium oxide by Osann, and found it to consist chiefly of SiO₂, TiO₂, Fe₂O₃, and ZrO₂; from this material Claus isolated a new metal, to which he assigned Osann's name, ruthenium.

Formation. — 1. By reducing Ru₂O₃ by heating in H or C.—2. By strongly heating (NH₄),RuCl₃, (NH₄)₂RuCl₃, Ru(NH₄,NH₂Cl)₂, decided by heating RuSn₂in Ru(NH₂NH₂Cl)₂.—3. By heating RuSn₂in

a graphite boat in a stream of HCl.

Preparation. - Deville a. Debray (C. R. 82, 926) prepared pure Ru by heating the ordinary metal in a stream of O till every trace of Os was removed as OsO, (vol. iii. p. 646), fusing with KOH and KNO, dissolving in water, saturating with Cl, and distilling off RuO, into KOHAq, by heating in a stream of Cl on a water-bath, ppg. Ru₂O₃ by adding alcohol to the solution of KRuO,, heating the pp. in coal-gas till reduced to Ru, melting in a graphite crucible with 5 to 6 parts pure tin, treating with boiling HClAq, washing and drying the crystalline RuSn₂ which remained, and heating this strongly in a graphite boat in a stream of HCl .- 2. Osm-iridium is mixed with 2 parts KNO, and 1 part KOH, and the mixture is heated to redness in a large silver crucible, embedded in MgO in an carthenware crucible; the molten portion is poured off, and the residue is heated with more KNO, and KOH. The fused mass is lixiviated with water; the orange solution, which contains KOH and K salts of HNO2, HNO3, H₂OsO4, and H₂RuO4, is neutralised by HNO3Aq, when a black pp. forms containing OsO2.xH2O and Ru,O,xH,O. This pp. is filtered off, the filtrate being set aside, and is washed and boiled with HClAq and HNO, Aq in a retort connected with a receiver which is kept very cold; the boiling is continued till a drop of the distillate, when brought alternately into the oxidising and reducing parts of the Bunsen flame, ceases to give a bright flash in the former, i.e. until OsO. ceases to distil off. The residue, which contains RuCl₂ and RuCl₃, is dissolved in a little water, excess of NH Cl is added to the hot conc. solution, the liquid is poured off from (NH,) RuCl, evaporated and mixed with more NH4Cl, when (NH4)2RuCl ppts. Excess of NH,Cl is removed from the pps. by washing with alcohol. By strongly heating the pps. Ru is obtained. The solution filtered from the pp. of OsO2.xH2O and Ru2O3.xH2O contains OsO4 and RuO,; it is made strongly acid by HClAq, OsO, is distilled off, the solution is evaporated till most of the KNO, crystallises out, the mother-liquor is evaporated to dryness, the residue is dissolved in water, and Ru₂S₃ is ppd. by adding (NH₄)₂SAq and then acidifying; after washing and drying, the Ru₂S₃ is roasted, and the Ru₂O₄ so formed is reduced by heating in H, or by strongly heating in a graphite crucible; or the Ru,O, may be dissolved in HClAq, and NH,-Ru chlorides obtained from this solution and decomposed by heat (Claus, J. pr. 85, 129; Carey Lea, Am. S. [2] 38, 83).

For other methods of separating Ru from osm-iridium v. Deville a. Debray (A. Ch. [3] 56, 886; C. R. 83, 927; Fremy, A. Ch. [3] 44, 385; Gibbs, Am. S. [2] 34, 343; 37, 61). Debray obtained ruthenium in crystals by dissolving the spongy metal in molten lead, heating strongly, and, after cooling, dissolving out the lead (with which Ru does not alloy) in HNO₂Aq (C. R. 90,

1195).

Properties .- A white, lustrous, hard, heavy, brittle metal. As obtained by heating the double ammonium chlorides, Ru forms a white spongy mass; the metal formed by reducing the oxide by H appears in white porous fragments, which can be powdered; after fusion in an electric furnace Ru appears greyish (Joly, C. R. 116, 430). Next to Os, Ru is the most infusible metal; small pieces can be melted at the highest temperature of the O-H flame (D. a. D., A. Ch. [3] 56, 385); a little RuO₄ is formed and then decomposed to RuO₂ (D. a. D., C. R. 80, 457). Insoluble in all acids if in compact pieces; very finely divided Ru dissolves slightly and slowly in boiling aqua regia. Not attacked by molten KHSO,; oxidised to K.RuO, by fusion with KOH, KNO, or KClO, Ru dissolves in molten Zn or Pb; treatment with HNO Ag leaves the Ru undissolved. Small quantities of Ru when alloyed with Pt metals soluble in acids go into solution, with the Pt metals, in these acids. Finely divided Ru combines with O, when heated in O or in air.

Ru is closely related to Rh and Pd, and less closely, but very distinctly, to Os, Ir, and Pt;

v. Noble metals, vol. iii. p. 628.

The atomic weight of Ru has been determined (1) by determining the ratio of Ru to KCl in K,RuCl₃ (Claus, P. 65, 218 [1845]; (2) by analyses of the salts M,Ru(NO)Cl₃, where M=K, Na, and NH₄ (Joly, C. R. 107, 994; 108, 946 [1889]; (3) by determining V.D. of RuO₄ (Debray a. Joly, C. R. 106, 328); (4) by measuring S.H. of Ru (Bunsen, P. 141, 1). Claus's determinations gave values from 102-2 to 104-8 for the at. wt.

The only compound of Ru whose mol. weight is known in the gaseous state is RuO₄; the valency of the atom of Ru cannot be determined

from this datum.

Reactions and Combinations.—1. Finely divided Ru, when heated to redness in air or in oxygen, rapidly absorbs 18.6 p.c. O (Claus, J. pr. 42, 364); after 10 hours, c. 23 p.c. O has combined (D. a. D., C. R. 87, 441); the product is a mixture of RuO₂ and Ru (Claus failed to obtain a lower oxide than RuO₂ in this way). Crystals of RuO₄ are obtained by heating the metal in a tube in a rapid stream of O; according to Debray and Joly (C. R. 106, 1494), RuO₄ is formed and then decomposed (v. RUPHENIUM TETROXIDE, p. 417).—2. Heated in chlorine, a small portion is changed to a chloride; mixed with sodium chloride and heated in chlorine, Na_RuO₄ is formed (Claus, l.c.).—3. Spongy Ru is said to form HOlAq when placed in chlorine vater; and to produce chlorides in solutions of hypochlorites, O being given off (Schönbein, J. pr. 98, 76).—4. Very finely divided Ru dissolves slightly when kept in boiling aqua regia for some time, RuOl₂ being formed,—5. M₂RuO₂

soluble in water. is formed by fusing Ru with caustic alkalis, alkali chlorates, or alkali nitrates. Alkaline earth nitrates or chlorates also form ruthenates (v. RUTHENATES, p. 417).

Detection.—A few mgms. of the substance to

be tested are heated, in a spoon of Pt, with excess of KNO, until the whole melts and ceases to give off gas; when cold, the mass is dissolved in water, when a strongly coloured orange-yellow solution is obtained; a little HNO3Aq is added to this solution, followed by HClAq, and warming till the voluminous black pp., produced by HNO, Aq, dissolves to an orange-yellow solution; H,S is passed into this liquid, until it appears black from the presence of suspended Ru sulphide (or oxysulphide); on filtering, an azure-blue liquid is obtained, probably containing RuCl₂ (Bunsen, A. 146, 265). For estimation v. Deville a. Debray (C. R. 83, 927).

Ruthenium, alloys of. An alloy with iridium was obtained by Deville a. Debray (A. Ch. [3]. 56, 385). A crystalline alloy with tin, RuSn, is formed by melting Ru with 10 to 15 parts Sn, and when cold treating with HClAq. The tin is removed, and crystalline Ru remains, by heating, in a graphite boat, in HCl gas (D. a. D., l.c.; v. also C. R. 83, 927). Ru alloys with zinc; much heat is produced (D. a. D., l.c.). Ru dissolves in molten lead, but separates out again on cooling (Debray, C. R. 90, 1195).

Ruthenium, ammonio-salts of; v. RUTHE-

NIUM-AMMONIUM COMPOUNDS, p. 418.

Ruthenium, chlorides of. Two chlorides,
RuCl₂ and RuCl₃, are obtained by heating finely divided Ru in a stream of Cl. No other chloride has been isolated; the existence of double compounds of RuCl, with alkali chlorides is doubtful. The molecular weights of the chlorides are not known.

RUTHENIUM DICHLORIDE RuCl₂. (Ruthenous oride. Ruthenoso-chloride.) Prepared by chloride. Ruthenoso-chloride.) heating very finely divided Ru in a stream of Cl. Action begins at c. 360° (Joly, C. R. 114, 291) with formation of RuCl, which is removed by subliming, and the temperature is kept at dull redness for an hour or two; the residue is powdered, and again heated in Cl; and this treatment is repeated several times (Claus, A. 59, 234). A black crystalline mass; insoluble water, acids, or alkali solutions. The azureblue liquid formed by the action of reducers, such as Zn or H2S, on solutions of RuCl., was thought by Claus (i.c.) to contain RuCl,

RUTHENIUM TRICHLORIDE RuCls. (Rutheno-, or ruthenoso-ruthenic, chloride. Sesquichloride of ruthenium.) Obtained, as a brown, crystalline, very hygroscopic solid, by dissolving Ru(OH), (Claus, A. 59, 234), or RuO, (Joly, C. R. 107, 994), in HClAq, and evaporating to dryness. Joly (C. R. 114, 291) obtained RuCl, by heating finely divided Ru at 360° to 440° in a mixture of CO and Cl, the Cl being in excess. Claus says that RuCl, is sol. water, with partial decomposition to an insol. oxychloride; and that, on heating, the solution decomposes with separation of a black powder (partly oxychloride, partly RuO.H.), the colouring power of which is so great that 1 mgm. suffices to make 500 c.c. water appear quite black. Joly (C. R. 114, 291) says that RuCl, prepared by heating Ru in Cl and CO. is insol, cold water, acid solutions, CCl., CS,

CHCl, Et,O, or PCl, it is decomposed slowly by hot water; slowly dissolved by digesting with 50 times its weight of absolute alcohol, in a sealed tube. Solution in alcohol is purple-violet; slowly decomposes in moist air, more rapidly at 60°, giving RuCl. OH (v. RUTHENIUM HYDROXYchioring, p. 416). Rull, absorbs NH, to form 2Rull, 7NH; another compound containing NH,, viz. Rull, (OH), 7NH, 3H,O, is formed by throwing RuCl, in small successive quantities into cold saturated NH, Aq and then heating to 40° (Joly, C. R. 115, 1299).

Double salts. Chlor-ruthenites, RuCl₁.2MCl, or M_2 RuCl₃; $M=NH_4$, K, Na(Claus, A. 59, 234; 63, 359). Formed by evaporating RuO,H, in HClAq nearly to dryness, dissolving in water, and adding conc. solution of the alkali chloride; also by heating a mixture of Ru with KCl or NaCl in Cl (Joly, C. R. 107, 994). The potassium salt, which seems to be the most definite, is a brownish-violet, crystalline powder, scarcely sol. cold water, somewhat sol. boiling water, insol. alcohol of 80 p.c.

Joly (C. R. 108, 854) obtained ruthenium nitrosochloride RuCl, NO.H.O, by heating RuCl, with a large excess of HNO, Aq, and evaporating at 120°. Heated in vacuo, or in CO₂, at 440°, gives off NO, and leaves a mixture of RuCl₃ and RuO₂. Solution of the nitroso-chloride is not ppd. by alkalis in the cold; but on boiling with enough alkali to combine with 3Cl, a brown gelatinous pp. of nitroso-oxide, Ru₂O₂,2NO.2H₂O₃ is obtained. For compounds of RuCl₂ with NO and alkali chlorides, v. Nitrosochlor-ruthenates, infra.

RUTHENIUM TETRACREORIDE RuCl. (Ruthenichloride. Ruthenic chloride.) Claus (4. 59, 234) supposed that a solution of RuO, H, in HClAq contained this chloride; he also described various alkali chlor-ruthenates, M.RuCl. obtained by adding alkali chlorides to the supposed solution of RuCl. Joly, however (C. R. 107, 994), has shown that Claus' salts contain NO; and he asserts that the compound used by C. and supposed to be RuO, H, itself contained NO. Joly failed to obtain either RuCl, or the salts M.RuCl_a. The compounds described by C. as M.RuCl_a, but shown by J. to be M.Ru(NO)Cl_b. may be called nitrosochlor-ruthenates.

Nitrosochlor-ruthenates, $M_Ru(NO)Cl_*(RuCl_*,NO.2MCl)$. M = Am, K, Na. These salts were obtained by Joly (C. R. 107, 994) by heating RuCl, in HNO, Aq for some time and adding alkali chlorides, also by adding alkali nitrites to warm solutions of RuCl, in HClAq. According to Joly, the salts described by Claus as M.RuCl, are in reality nitrosochlorruthenates. These salts yield NO when heated with CaCO₃. Solutions of these salts are not ppd. by alkalis in the cold; on boiling with alkali sufficient to combine with 3Cl, a pp. of Ru₂O₃(NO)₂.2aq is slowly formed (J., C. R. 108, 854). The group NO evidently forms part of the acidic radicle of the salts (cf. RUTHENIUM-AMMONIUM COMPOUNDS. p. 418).

Potassium nitrosochlor-ruthenate,

K,Ru(NO)Cl,. Prepared by fusing Ru with KOH and KNO, dissolving in HClAq, and evaporating somewhat till excess of KCl and KNO, crystallise out; by evaporating the mother-liquor a mixture of K.RuCl, and K.Ru(NO)Cl, is obtained, from which water dissolves the latter salt. Purified by crystallisation from water, wherein the salt is fairly soluble. Black, orthorhombic prisms; transparent when in thin crystals. Solution in water is violet-red.

Ruthenium, cyanide of, and derivatives; v. vol. ii. p. 346.

Ruthenium, hydroxides of; v. Ruthenium, oxides and hydrated oxides of, in/ra.

Ruthenium, hydroxychloride of, Ru(OH)Cl₂. Described by Joly (C. R. 114, 291) as a solid, obtained by heating, in moist air to 60°, a solution of RuCl₃ in absolute alcohol. Very solwater; the deep indigo-blue solution slowly denosits RuO H.

Ruthenium, iodide of, RuI₃. This compound is formed, according to Claus (A. 59, 234), as a black pp. by adding KI to K_{*}RuCl_{*}Aq.

Ruthenium, nitrosochloride of, Ru.NO.Cl., v. under Ruthenium TRICILORIDE.

Ruthenium, nitrosopentoxide of,

Ru₂(NO)₂O₃.2H₂O, v. under Ruthenium pentoxide.

Rutenium, oxides and hydrated oxides of. Claus described four oxides of Ru: RuO, RuO, RuO, RuO, and RuO,; and the hydrated oxides Ru,O,3.3H₂O and RuO,2H₂O. According to Debray and Joly, RuO and Ru,O,3 have not been isolated, but the oxides Ru,O,3 and Ru,O, exist, besides RuO, and RuO,. According to Joly, Claus' RuO,2H₂O contains NO. Ru combines with O when melted in the O-H flame, with formation of RuO,; it is probable that RuO, is tormed, and then decomposed to RuO, + O.

RUTHENIUM MONOXIDE RuO. (Ruthenous oxide.) According to Claus (A. 59, 234), this oxide is formed, as a dark-grey, metal-like solid, by calcining RuCl₂ mixed with rather more than an equivalent of Na₂CO₃ in a stream of CO₂, and washing with water as long as anything dissolves. Debray and Joly (C. R. 106, 328, 1424) could not obtain this oxide.

RUTHENTIM SESQUIONIDE Ru₂O₃. (Ruthenocxide.) When Ru black is strongly heated in a Pt crucible, c. 18·5 p.c. O is rapidly taken up; O is then slowly absorbed till from 23 to 24 p.c. has combined, and a blue-black mass is formed. This blue-black solid is Ru₂O₃, according to Claus (A. 56, 257; 59, 231); according to D. a. J. (l.c.) it is a mixture of Ru and RuO₃.

HYDRATED RUTHENIUM SESQUIOXIDE
Ru₂O₃3H₂O or RuO₂H₂. (Black ruthenium hydroxide.) A black powder; prepared by ppg. solutions of RuCl₂ by alkali, or by alkali carbonate, phosphate, or borate (Claus, A. 59, 234). Also ppd.from an aqueous solution of Ru(Ol)Cl₂ (v. Hydroxychloride, supra). Even after washing for several days the pp. retains c. 1 p.c. alkali. Reduced, but incompletely, by H at ordinary temperature. Insol. KOHAq or NaOHAq, sl. sol. NH,Aq (Claus, l.c.); sol. in acids. The only salts of oxyacids derived from this oxide which have been prepared are Ru(NO₂)₃3KNO₂ and the corresponding Na salt (Claus, J. 1863. 697; Gibbs, Am. S. [2] 29, 427; 31, 63; 34, 341).

RUTHENTOM DIOXIDE RUO. (Ruthenic oxide.) Formed by strongly heating Ru sulphide, or Ru(SO.),, in air (Claus, A. 59, 234). Ru(SO.), is obtained by ppg. RuCl, solution by H.S., and oxidising the pp. by HNO. RuO. is also formed, as a crystalline sublimate, by roasting osm-

iridium containing Ru in a porcelain tube (Fremy, A. Ch. [3] 44, 385). Also obtained by strongly heating finely divided Ru for some time in a stream of O (D. a. D., A. Ch. [3] 56, 385; C. R. 83, 927; 87, 441). The whole of the Ru is not converted into RuO₂, but some metal remains unoxidised (D. a. J., C. R. 106, 1494). At a very high temperature RuO₄ is formed, and at a lower temperature this is resolved into RuO₂ and O (D. a. D., C. R. 80, 457; D. a. J., C. R. 106, 1424). D. a. J. (C. R. 106, 328) obtained RuO₂, partly amorphous and partly crystalline, by heating RuO₄ to 107°; also by heating RuO₄ to 440°.

Dark-violet, quadratic crystals; isomorphous with rutile (Fremy, l.c.; D. a. J., l.c.). S.G. 7.2 (D. a. D., A. Ch. [3] 56, 385). Insol. acids, sol. molten KOHAq. Easily reduced by H. The only salt of an oxyacid corresponding with RuO₂ which has been isolated is Ru(SO). (Claus. l.c.).

which has been isolated is Ru(SO₄)₂ (Claus, *l.c.*).

Hydrafed ruthentum disciple RuO₂.5H₄O or RuO₁H_{1.3}H₄O. The existence of this compound is doubiful. Claus (4.59, 234) gave this composition to the gelatinous, yellow-brown pp. formed by decomposing K₂RuCl₂Aq by Na₂CO₃; but Joly has shown that Claus' K₄RuCl₂ contains NO (cf. Ruthentum tetrachloride, p. 415). Claus also obtained hydrated RuO₂ by evaporating Ru(SO₄)₂Aq with KOHAq; but as the sulphate employed was obtained by oxidising Ru sulphide by HNO₃, it may have contained NO. Joly (C. R. 107, 994) gives the formula Ru₂O₃(NO)₂2H₂O to to the brown gelatinous pp. formed by boiling Ru(NO)Cl₃ or K₂Ru(NO)Cl₃ with KOHAq or K₂CO₃Aq. It seems probable that Claus' RuO₂.5H₃O is the same as the nitroso-compound obtained by Joly (cf. infra Hydrated nitroso-pentoxide).

RUTHENIUM PENTOXIDE Ru.O. (= RuO.,RuO.). When RuO. Ag stands for some time in a closed vessel, a black pp. settles down and a black crystalline crust forms on the sides of the vessel, while O is set free and escapes when the vessel is opened. The composition of the pp. and crystalline crust after drying at 100° is given by Debray a. Joly as Ru.O. (C. R. 106, 328). This oxide is also obtained by allowing a dilute solution of a ruthenate to stand for a long time, or by adding a dilute acid to such a solution. Ru.O. dissolves in HClAq, giving off Cl; heated to 360° Ru.O. is formed.

Hydrated nitroso-pentoxide Ru₂O₃(NO)₂:2H₂O. A black solid, formed by boiling Ru(NO)Cl₃ or K.Ru(NO)Cl₃ (v. Nitrosochloride, and Nitrosochlor-ruthenates, p. 415) with sufficient alkali or alkaline carbonate to combine with 3Cl, and drying the pp. at 150° (Joly, C. R. 103, 854). Slowly decomposes when heated to 360° in CO₂, giving Ru₁O₂; above 440° decomposes violently, giving off N oxides; reduced by H below 100°, giving off NH₂. Sol. in acids, forming nitrososalts.

RUTHENIUM NONOXIDE Ru_4O_9 (= $3\mathrm{Ru}O_2,\mathrm{Ru}O_3$). This composition was given by D. a. J. (C. R. 1005, 328) to the black, lustrous, crystalline crust obtained by heating $\mathrm{Ru}O_4\mathrm{Aq}$ to 100° . The same oxide is formed by heating Ru_2O_3 to 860° . Heated to 440° this oxide gives amorphous $\mathrm{Ru}O_2$ and O.

RUTHENIUM TRI-OXIDE RuO. (Ruthenic anhydride.) This oxide has not been isolated,

but salts derived from it are known. RuO, is the hypothetical anhydride of ruthenic acid (H_RuO,), which has not been isolated. For the salts corresponding with this oxide v. Ruthenates, under Ruthenium, salts of oxyacids of, infra.

RUTHENIUM HEFTOXIDE Ru₂O_r. (Per-ruthenic anhydride.) This oxide, the hypothetical anhydride of the non-isolated per-ruthenic acid (HRuO₄), has not been prepared. For the salts corresponding with this oxide v. Per-ruthenates, under RUTHENIUM, SALTS OF OXYACIDS OF, infra.

RUTHENIUM TETROXIDE RuO. (Sometimes called per-ruthenic acid.) and frequently ruthenic acid.) Mol. w. 165-24. V.D. 83-3 at 100° and 106 mm. pressure (Debray a. Joly, C. R. 106, 328).

Formation.—1. By passing Cl into a solution of the product of fusing Ru with KOH and KNO₃,—2. By the action of KClO₃ and HCl, not aqua regia, on K₂RuCl₃Aq (Claus, A. 59, 234).—3. By heating finely divided Ru in a stream of O to c. 1000°, and cooling rapidly by means of ice. If the temperature is allowed to fall slowly the RuO₄ formed decomposes explosively at c. 108° (Debray a. Joly, C. R. 106, 100).

Preparation.—A mixture of 1 part finely divided Ru, with 8 parts KOH and 1 part KNO, is heated to dull redness in a silver crucible till fused; the product, when cold, is dissolved in 16 parts water; the solution is placed in a tubulated retor; connected, by a long tube, with a very well cooled receiver (the connecting tube being also cooled), and a rapid stream of Cl is passed into the solution; a considerable amount of heat is produced, and RuO, passes over and solidifies in the receiver (Deville a. Debray, A. Ch. [5] 4, 537). To free the preparation from water D. a. J. (C. R. 106, 328) place it in a tube with fused CaCl₂, contract the tube in the middle, pump out the air, and seal off the tube. The RuO, slowly sublimes into the upper part, which is then separated from the rest. The RuO, is finally distilled in vacuo into tubes which have been very carefully cleansed from all traces of organic matter, and dried by heating to redness in a stream of H. RuO, may be obtained in well-formed crystals by subliming in vacuo at the ordinary temperature.

Properties .-- (D. a. J., C. R. 106, 328.) Golden yellow crystals, melting at 25.5° to an orange-red liquid, which solidifies slowly to a vitreous solid. Smell resembles that of ozone; the vapour causes coughing, but does not affect the eyes (Claus, J. pr. 80, 282). Sublimes at 3 to 4 mm. pressure on the slightest rise of temperature; the vapour is golden yellow. Decomposes at 106°-107° without boiling. The vapour-pressure of the crystals is almost nil at 0°, 20 mm. at 42°, and 182 mm. at 100.8°. May be distilled in water-vapour containing Cl or HClO. Gradually reduced to RuO₂ by sunlight (Joly, C. R. 113, 693). Dissolves in water, forming a golden-yellow solution, which gradually decomposes with ppn. of Ru₂O₃xH₂O. RuO₄ attacks Hg, and slowly acts on glass. RuO₄ does not form corrections of the contraction of the contractio responding salts, either by reacting with acids or alkalis. Moist RuO, is very easily reduced, e.g. by contact with paper.

Reactions.—1. Decomposed by heat; no ac-

tion below 106°; at 107° sudden decomposition occurs, with a smoky flame and formation of amorphous RuO2 on the walls of the vessel, and crystalline RuO, from the part that has melted (D. a. J., l.c.). According to D. a. J. (C. R. 106, 100), RuO₄ is formed when O is passed over spongy Ru at c. 1000°, and the product is rapidly cooled. If cooling is allowed to take place slowly the RuO, decomposes at c. 108° .-2. Dissolves in water; solution keeps unchanged for some time, but slowly deposits Ru,O,xH,O. Decomposition is more rapid at higher temperatures; at 100° Ru,O, xH,O is formed (D. a. J., l.c.).—3. Solution in water, or moist RuO, is quickly reduced by alcohol and several other organic compounds (Claus, J. pr. 80, 282) .-4. With solutions of alkalis forms ruthenates and per-ruthenates, with evolution of O. Alcoholic solution of potash ppts. Ru₂O₂.3H₂O₂.— 5. Heated with hydrochloric acid, Cl is given off and RuCl, formed in solution .- 6. Hydrogen sulphide gradually throws down a black pp. of an oxysulphide, from RuO, Aq (Claus, l.c.).

Ruthenium, oxyscids of. No oxyscid of Ru

Ruthenium, oxyacids of. No oxyacid of Ru has been isolated, but some salts of the hypothetical acids H₂RuO₄ and HRuO₄ are known (v. RUTHENIUM, SALTS OF OXYACIDS OF, infra).

Ruthenium, oxysulphide of. A current of H₂S passed into Ru₀/Aq slowly ppts. all the Ru as a black substance, which is said by Claus (J. pr. 80, 282) to be an oxysulphide, whose composition varies according to the quantity of H₂S passed in. The pp. suddenly glows when dried at 100°, and burns, giving off SO₂.

Ruthenium, saits of. Very few saits are known obtained by replacing the H of oxyacids by Ru. The double nitrites Ru(NO₂)₃.3MNO₃, where M = K or Na, are the only saits which have been prepared corresponding with Ru₂O₃; and Ru(SO₄)₂ is the only sait of RuO₂ which has been isolated; the double sulphite RuSO₃.K₂SO₃ corresponds with RuO.

Buthenium, salts of oxyacids of. A few salts of the hypothetical acid HRuO, and two salts of the hypothetical acid HRuO, have been isolated.

RUTHENATES, M¹₂RuO₄. Salts of hypothetical H₂RuO₄ (formerly called ruthenites). These salts are formed by heating Ru, or an oxide of Ru, with an oxide, hydroxide, nitrate, or chlorate of an alkali metal (Claus, A. 56, 257; 59, 234), or of an alkali metal (Claus, A. 56, 257; 59, 234), or of an alkaline earth metal (Deville a. Debray, A. Ch₂ [3] 56, 385). Ruthenates in solution are easily reduced by organic bodies, with ppn. of black Ru₂O₃.3H₂O; acids added to cone. solutions form per-ruthenates, M¹RuO₄.

Barium ruthenate BaRuO, aq. Obtained by adding RuO, to BaOAq. The solution is at first green, probably from formation of perruthenate; a black pp. is thrown down, which soon changes to the cinnabar-coloured crystalline Ba sait. This salt is also formed by adding BaCl,Aq to a solution of the K salt (Debray a. Joly, C. R. 106, 1494).

Potassium ruthenate K_RuO₄.aq (D. a. J., l.c.). 50 g. RuO₄, melted under water, are slowly added to 70 g. KOH in 500 c.c. water at 60°; temperature is kept at 60° until the evolution of O has ceased, when the solution is evaporated in vacuo; long, black, orthorhombic prisms, reflecting green light, are formed (for

crystalline measurements v. D. a. J. (l.c. p. 1497). After drying in vacuo, the crystals absorb moisture and CO₂ from the air. Unchanged at 106° in vacuo; loses H₂O at 200°, and may then be heated to 100° without decomposition. Very sol. water; solution is orange yellow; it soon decomposes in air, depositing Ru₂O₅.xH₂O, and probably forming KRuO Aq. Organic bodies dipped into the solution become black from deposition of Ru₂O₃,8H₂O. Acids hasten formation of KRuO₄Aq and Ru₂O₅; from conc. K₂RuO₄Aq acids ppt. KRuO₄, which decomposes to Ru₂O₅ and RuO, (D. a. D., C. R. 83, 927).

The magnesium, silver, and strontium salts are obtained by adding MgCl2Aq, AgNO3Aq, and SrCl2Aq respectively to K2RuO, Aq. The sodium salt has not been isolated; it cannot be separated

from excess of soda.

PER-RUTHENATES, MIRUO. Salts of hypothetical HRuO, (formerly called ruthenates). Obtained by the action of Cl on ruthenates, or of acids on conc. solutions of ruthenates. Alkalis produce ruthenates from solutions of per-ruthenates.

Potassium per - ruthenate KRuO. (Deville a. Debray, C. R. 83, 927). 50 g. RuO melted under water, are slowly added to 60 g. KOII in 250 c.c. water at 60°; O is evolved, and the solution becomes green; after O ceases to come off, the liquid is allowed to cool in a closed vessel; the cold (red) liquid, which contains K_RuO₄, is poured off, and the crystals of KRuO₄ that adhere to the sides of the vessel are dried in vacuo on an unglazed porcelain plate. Black, opaque, quadratic pyramids (for crystallographic measurements v. D. a. J., C. R. 106, 1496). Unchanged in air after drying in vacuo; decomposes suddenly at 440°, giving off O (? with formation of K₂RuO, and RuO₂). Cl reacts in the cold to form RuO, and KCl. Slightly sol. water; solution is blackish-green and soon decomposes, KOH being formed. Alkalis added to KRuO, Aq produce K, RuO, Aq, with evolution of O.

The sodium salt, NaRuO, aq, has been isolated; it forms black crystals. Addition of chlorides of alkaline earths to solution of KRuO, or NaRuO, ppts. M"RuO, not M"(RuO), and

the solutions contain RuO₄.

Ruthenium, sulphides of. No sulphide of Ru has been isolated with certainty. Claus could not obtain a sulphide by heating Ru with S in CO₂ (A. 56, 257; 59, 234). The pps. formed by H2S in solutions of Ru compounds vary in composition, and contain free S. By ppg. RuCl, solution by H2S, and heating the solid in CO, S and H₂O are given off, and a greyish-black metal-like substance remains, which is perhaps Ru, S, (C., l.c.). The pp. which H, S produces in RuO, Aq is probably an oxysulphide (q.v.). The mineral laurite, from Borneo and Oregon, contains Ru₂S₃ with Os sulphide (Wöhler, A. 139, 116; 191, 374). M. M. P. M.

RUTHENIUM-AMMONIUM COMPOUNDS. Ruthenammines. Ammoniacal ruthenium bases.) These compounds have not been obtained by treating Ru chlorides with NH,Aq. The starting-point for the compounds described by Claus was RuCl, 2NH, Cl. By treatment with NH, Aq, Claus obtained RuCl, 4NH, 3aq, and from this he prepared various salts RuX, 4NH,

where X = monovalent acidic radicle (N. Petersb. Acad. Bull. 1, 97; 2, 158). By evaporating a solution of the base Ru(OH), 4NH, in vacuo over H.SO., Claus obtained a new base, to which he gave the formula Ru(OH), 2NH, 4aq; he did not prepare any salts of this base. Joly (C. R. 107, 994) found that Claus' RuCl, 2NH, Cl is a nitroso-compound, and has the composition RuCl₃NO.2NH,Cl. Joly also showed (C. R. 108, 1300) that Claus' RuCl₂4NH₃ has the composition RuCl2-NO.OH.4NH3, and that the Rux, NO.OH.4NH,. Whether the base described by Claus as Ru(OH), 2NH, contains NO or not has not been determined; it is described here provisionally.

The nomenclature adopted in this article must be looked on as only provisional.

NITROSO-RUTHENI-DIAMMINES,

X.NO.Ru(NH₃.NH₃R)₂; R may or may not be the same as X. (Joly, C. R. 108, 1300; 111, 969.) Described by Claus as ammonium ruthenoso-di ammonium compounds, N2H4(NH4)2Ru.X2, or ruthenoso-diammines, Ru(NH, NH,X)2

Series I. Hydroxy-compounds,
OH.NO.Ru(NH₃,NH₂R)₂. The chloride, R = Cl,
was obtained (Joly, C. R. 108, 1300) by boiling
Ru(NO)Cl₃ (described under Rutherium Tri-CHLORIDE, p. 415) with excess of NH₂Aq, until the liquid became golden yellow, and deposited orange-yellow crystals of the salt. The bromids R = Br, and *iodide* R = I, were prepared similarly. The carbonate R = 1 CO3, nitrate R NO3, and sulphate $R = \frac{1}{2}SO_{\bullet}$, were prepared by the reaction of the chloride with Ag salts. By reacting on the chloride with moist Ag.O, Joly obtained a strongly alkaline liquid which probably contained the hydroxide, R=OH. The chloride

forms a double compound with PtCl.

Series II. Chloro - compounds,
Cl.NO.Ru(NH₂,NH₂R)₂ (Joly, C. R. 111, 969). The chloride, R = Cl, was obtained by dissolving the hydroxy-chloride in much HClAq, evaporating, and crystallising from boiling water; it combines with PtCl. The bromide and iodide, R=Br and I, were obtained similarly to the chloride.

Series III. Nitrato - compounds, NO3.NO.Ru(NH3.NH3R)2. The nitrate, R = NO3, was formed by the action of AgNO, Aq, or boilling HNO, Aq, on the chloro-chloride (J., l.c.). Series IV. Sulphato-compounds

Series IV. Sulphato-compounds, SO, 2[NO.Bu(NH, NH, R),]. Two sulphates, the normal salt where $R = \frac{1}{2}SO$, and the acid salt $2(SO, 2[NO.Bu(NH_2, NH_3, NG), SO])$. He SO, were obtained by the action of H_2SO_4Aq on the chlorochloride.

These compounds give off NH2 when heated in KOHAq, and separate Ru nitroso-hydroxide Ru(OH), NO, from which nitroso-salts are ob-

tained by the action of acids.

??Ruthenos-ammines, Ru(NH,X), or ruthenos-diammonium compounds, NH,(NH,)Ru.X, The only compound of this class which has been isolated is the hydroxide, Ru(NH, OH), 4aq, obtained by Claus (N. Petersb. Acad. Bull. 1, 97; 2, 158) by evaporating, over H₂SO, in vacuo, a solution of the base to which he gave the formula Ru(NH, NH, OH),. As the compound from which Claus obtained the supposed ruthenos-ammine hydroxide has been found

to contain NO, it is probable that the product of evaporation was also a nitroso- compound. M. M. P. M.

RUTIN C₀H₃₀O₃₃. [above 190°]. S. 58 at 100°. S. (boiling alcohol) 20. S. (ether) 29. Extracted by alcohol or HOAc from the leaves of the garden rue (Ruta graveolens) (Weiss, Pharm. Centr. 1842, 903; Bornträger, A. 53, 885; Förster, B. 15, 217). Occurs also in capers, the flower-buds of Capparis spinosa (Rochleder a. Hlasiwetz, A. 82, 197; 96, 123; Zwenger a. Dronke, A. 123, 145), in sattlower (Stein, J. pr. 58, 399; 88, 280), in rose leaves (Filhol, J. 1863, 594), and in the leaves of the buck-

wheat (Polygonum Fagopyrum (Schunck, C. J. 53, 262). Crystallises from water in pale-yellow needles (containing 3aq). Sol. alkalis, forming a yellow solution, from which it is reppd. by acids. FeCl, gives a dark-green colour. Lead acetate added to its alcoholic solution forms a yellow pp. Pb₃C₄₂H₄₄O₂₅. Does not reduce Fehling's solution. Decomposed by boiling dilute H.SO, into quercetin (1 mol.) and isodulcite (3 mols.).

RUTYL. A name sometimes used for decoyl

C10H19O or decyl C10H21.

RUTYLENE v. DECINENE.
RUTYLIDENE v. HENDECINENE.

 \mathbf{S}

SACCHARIC ACID C.H 10O, i.e. СО, Н.СН(ОН).СН(ОН).СН(ОН).СН(ОН).СО, Н. Mol. w. 210. Formed by the action of nitric acid (6 pts. of S.G. 1.15) on dextrose (glucose), and therefore on cane sugar and on milk sugar (Scheele, Opuscula, ii. 203; Trommsdorff, A. 8, 36; Guérin-Varry, A. Ch. [2] 49, 280; 52, 318; 65, 332; Erdmann, A. 21, 1; Hess, A. 26, 1; Thauloff, A. 27, 113; Liebig, A. 30, 313; 113, 1; Heintz, P. 61, 315; 105, 211; 106, 93: 111, 265, 291; A. 51, 185; Tollens, B. 21, 2149). Formed also by oxidation of dextrin, maltose, and dextrose by Br, and subsequent addition of ZnCO₃ (Herzfeld, A. 220, 352), and by the action of Br on glycuronic acid (Thierfelder, B. 19. 3148).

Preparation.-1. Dextrose (5 g.) is evaporated with HNO, (30 c.c. of S.G. 1.15) to a thick syrup. The syrup is dissolved in water (20 c.c.) and neutralised with K2CO3; HOAc is then added and the solution evaporated until the acid K salt crystallises out (Tollens, A. 249, 218) .-2. Starch (100 g.) is ground up with water (100 c.c.), poured into HNO, (500 c.c. of S.G. 1.15), and heated on the water-bath till red fumes begin to come off. The temperature is then lowered and kept at 65° until syrupy. The product is converted as above into the acid K salt (20 g.), which is dissolved in water, neutralised with ammenia, and ppd. by AgNO3. The Ag salt is then decomposed by HCl (Sohst a. Tol lens, A. 245, 4).

Properties. - Brittle deliquescent mass, v. sol. water and alcohol, v. sl. sol. ether. Dextrorotatory, [a]D varying from 8° to 38°. Reduces auric chloride and ammoniacal AgNO, (forming a mirror) but not Fehling's solution (Kiliani, B. 14, 2529).

Reactions .- 1. Oxidised by HNO, to dextrotartaric, racemic, and oxalic acids.—2. Potash at 250° yields acetic and oxalic acids. — 3. PCl, forms chloromuconic acid C.H.Cl.O. [260°] (Bell, B. 12, 1272).-4. Boiling dilute (30 p.s.) HClAq forms dehydromucic acid (S. a. T.; Schrötter, M. 9, 442).—5. HIAq and P at 150° forms some adipic acid (De la Motte, B. 12, 1572) .- 6. The ammonium salt decomposes at 1572).—6. The aminomian sais decomposes 160° into CO₂, NH₃, and pyrrole (Bella Lapper, B. 10, 1961). The ethylamine sait yields, in like manner, ethyl-pyrrole.—7. Phenyl-hydrasine sectate at 100° forms C₄H₄O₄(CO.N₃H₄Ph)₂, a

yellowish substance 210°], insol. water, alcohol. and ether; not decomposed by alcoholic potash

(Maquenne, Bl. [2] 48, 721).

Tetra-acetyl derivative of the ethyl ether C₈H₄Ac₄Et₂O₈. [61°]. Monoclinic tables (from alcohol), insol. Aq, v. e. sol. hot alcohol.

Anhydride C.H.O. i.e.

 $CH(OH) < CH(OH) > CH.CH(OH).CO_2H.$

charolactone. [132°]. Formed by allowing syrupy saccharic acid to stand over H₂SO, for some days (Sohst a. Tollens, A. 245, 5). Thin plates (from water). Yields pyromucic acid on heating. Reduced in acid solution by treatment with sodium-amalgam to glycuronic acid CO,H.CH(OH).CH(OH).CH(OH).CH(OH).CHO (Fischer a. Piloty, B. 23, 937; 24, 521).

Di-acetyl derivative of the double anhydride C10H10On i.e. CH(OAc).CHO.CO

[188°]. CO.O ___CH - CH(OAc). from Ac,O, acid potassium saccharate, and H.SO. (Maquenne, Bl. [2] 48, 720; cf. Baltzer, Bl. [2] 10, 263; A. 149, 238). White places, v. sl. sol. alcohol and ether.

Amide C₆H₈O₆(NH₂)₂. Amorphous powder Isosaccharic acid C₀H₁₀O₃. [185°]. [a]_D = 46° at 20°. Formed by careful oxidation of glucosamine hydrochloride by dilute HNO₄ (S.G. 1-2) (Tiemann, B. 17, 246; 19, 1258, 1273). Trimetric crystals (from water). v. sol. water and alcohol, sl. sol. ether. Dextrorotatory. Converted by heat into CO, and pyromucic acid. Reduced by HI to adipic acid. Heated in a current of dry HCl it yields fuzfurane (aa')-dicarboxylic acid. PCl, forms C₄H₂ClO(CO₂H)₂, which yields Et₄A'' [40°].... KHA" ½aq: v. sol. water.—(NH.);A".—BaA".— CaA".—SrA".—PbA" 2aq.—CuA".—Ag,A". Ethyl ether Et,A". [73°]. (250°). [a]p

Amide of the anhudride $C_4H_1O(OH)_2(CONH_2)_2[226^\circ]$. [a]_D = 7·2°. Anilide of the anhydride. [231°]

Acetyl derivative C,H, (OAc), (CO2H)2 aq.

[101°]. Needles (from water).

Parasaccharic acid C.H.O. Formed, together with glycyrrhetin, by boiling glycyrrhizin with dilute H2SO4 (Habermann, C. C. 1880, 253). Hygroscopic mass, sol. water and alcohol. Its salts are amorphous.

Metasaccharic acid CaH10O8. The salt CaA" aq, got by boiling an aqueous solution of the dianhydride with CaCO₂, forms crystals, sl. sol. water. KA' and Ag.C₂H₂O₃, have also been prepared (Fischer, B. 23, Zi21). Solutions of metasaccharates turn deep red when exposed to

Dilactone CaHaOa i.e. CH(OH).CH.O.CO l- Mannosaccharic CO . O.CH-CH(OH) acid. [68°]. S. 5.5 at 15°. $[a]_D = -202^\circ$ (Fischer, B. 24, 541). Formed by oxidation of acid. [68°]. S. arabinose-carboxylic (mannonic) acid C₆II₁₂O, by digesting its lactone with HNO₃ (S.G. 12) for 24 hours at 50° (Kiliani, B. 20, 341, 2710; 21, 1422). Long colourless needles (containing 2aq), sl. sol. alcohol, insol. ether. Readily reduces Fehling's solution. Reduced by HI to n-adipic acid. Sodium-amalgam reduces it to mannite. Phenyl hydrazine hydrochloride and sodium acetate solution in the cold form CH(OH).CH(OH)

CO . O.CH.CH(OH).CO.N₂H₂Ph [192°] crystallising in minute plates (containing aq), v. e. sol. hot water. Phenyl hydrazine hydrochloride and boiling sodium acetate solution forms C₄H₄(OH)₄(ČO.N₂H₂Ph)₂, crystallising in minute

plates [213°], v. sl. sol. water. Di-acetyl derivative of the dilactone

ÇH(OAc).ÇH.O.ÇO

CO.O -- CH-CH(OAc) [155°]. Formed by adding a few drops of H2SO, to a mixture of the dilactone and Ac.O (Kiliani, B. 22, 524). Prisms, v. sol. hot HOAc.

Г190°]. C4H4(OH)4(CO.NH2)2 Amide Formed from the lactone and NH, Aq. Monoclinic tables.

Dextro-metasaccharic acid. d-Mannosaccharic acid C_eH₁₀O₈. Salts.—CaA": crystalline powder.—BaA": minute tables, m. sol. water.— '.-CdA": minute tables, v. sl. sol. water.

Lactone $C_6H_6O_6$. [180°-190°]. [a]_D = 202° at 23°. Formed by oxidation of mannose, of mannite, or of d-mannonic acid by HNO, (S.G. 1.2) at 50° (Fischer a. Wirthle, B. 24, 539; Easterfield, C. J. 59, 306). Long needles (from alcohol or water), v. sol. hot water. Readily reduces Fehling's solution. Turns yellow on boiling with potash. Phenyl-hydrazine acetate in the cold

forms CH(OH).CH(OH).CON₂H.Ph [191°], while at 100° it forms C4H4(OH)4(CO.N2H2Ph)2 [212°], almost insol. hot water.

Amide C₆H₁₂N₂O₆. [189°]. Formed from the lactone and NH₂Aq in the cold. Crystals.

Inactive metasaccharic acid C_aH₁₀O₃. i-Mannosaccharic acid. The salts of this acid greatly resemble those of the preceding acid.

Lactone C.H.O. [c. 190°]. Formed by mixing equal parts of the dextro- and levolactones in aqueous solution. Formed also by oxidising i-mannonic lactone (E. Fischer a. Stanley Smith, B. 23, 2622; 24, 544). The aqueous solution is inactive to light, and gradually becomes acid on standing. Phenyl-hydrazine acetate reacts, forming in the cold CH(OH).CH(OH) CO.O — CH.CH(OH).CON,H,Ph [190°-195°]

and at 100° C,H,(OH),(CON,H,Ph), [220°-225°]. Amide. [185°].

SACCHARIN. The lactone of saccharinic acid (v. infra). The name has also been applied to the imide of SULPHOBENZOIC ACID.

SACCHARINIC ACID C.H.,O. i.e.

CH. (OH).CH(OH).CH(OH).CMe(OH).CO.,H.

Formed by boiling an aqueous solution of dextrose, lævulose, or invert sugar with lime (Péligot, Bl. [2] 36, 226; C. R. 90, 1141; Scheibler, B. 13, 2212). On setting the acid free it changes, especially on heating, into the anhydride. The salts are v. e. sol. water.—KA': monoclinic tables.—NaA'. [α]_D = -17·2°.—CaA'₂ (dried at 100°). Formed by boiling the lactone with water and CaCO₃. Amorphous. $[a]_D = -5.7^{\circ}$. CuA', 4aq: blue nodules (Kiliani, B. 15, 2955).

Anhydride $C_bH_{10}O_s$. [161°]. $[a]_D = 94°$. S. 13 at 15°. Electrical conductivity: Walden, B. 24, 2028. H.C. 656,900. H.F. 252,100 (Stoh-

mann, J. pr. [2] 45, 313).

Preparation.—A cold solution of 1 kg. of invert sugar in 9 litres of water is treated with 100 g. of powdered lime and allowed to stand, agitating at intervals. After 14 days 400 g. more CaO2H2 is added, and the mixture again allowed to stand for one or two months, until it no longer reduces Fehling's solution. It is then saturated with CO, the remaining Ca precipitated with oxalic acid, and the filtrate evaporated nearly to a syrup. The saccharin which separates is recrystallised from hot water; the yield is 100 g. (Kiliani, B. 15, 2954).

Properties .- Prisms, with bitter taste, v. sol. hot water. Dextrorotatory. Converted by alkalis into lævorotatory salts of saccharinic acid. May be volatilised almost without decomposition. Can be extracted by ether, even from solutions containing Na₂CO₃. Does not ferment with yeast. Does not reduce Fehling's solution, even after long boiling with dilute H.SO. Not attacked by dilute HNO₂. Gonc. HNO₃ forms oxalic acid and saccharonic acid C₆H₁₀O₄. 1 g. reduces 4.6 g. of KMnO₄. Oxidised by moist Ag₂O to formic, acetic, and glycollic acids. Boiling HIAq reduces it to the lactone of γ-oxyisohexoic acid CH, CH(OH).CH, CHMe.CO, H, which is further reduced by HI at 200° to CHMePr.CO.H (Liebermann a. Scheibler, B. 16, 1821; Kiliani, A. 218, 371). I and KOH give iodoform. Potash-fusion forms formic and lactic acids (Hermann a. Tollens, B. 18, 1333). Boiling HClAq has no action. Phenyl-hydrazine forms C₄H₁₁O₅(N₂H₂Ph) [165°], crystallising from alcohol in needles, v. sol. water (Fischer a. Passmore, B. 22, 2733). Phenyl cyanate at 165° forms Cathan, Oa, crystallising in silky needles

[230°-240°], v. sol. hot aniline, sl. sol. alcohol | crystals (containing aq), v. al. sol. ether. Conc. (Tesmer, B. 18, 2607)

Isosaccharinic acid C.H,2O. i.e.

CH,(OH).CH(OH).CH2.C(OH)(CO2H).CH2OH? Formed by the action of lime on malt-extract at 20° or on milk-sugar (Cuisinier, Bl. [2] 38, 512). The free acid at once splits up into water and lactone. The Na salt is levorotatory. - CaA'2.

8. 1 in hot water. Crystalline powder. Lactone C.H. 100. Isosaccharin. $[a]_p = 63^\circ$ in a 10 p.c. aqueous solution; = 74° in HOAc. Electrical conductivity: Walden, B. 24, 2028. Prepared by allowing a solution of milksugar (1 kilo) in water (9 litres) mixed with slaked lime (450 g.) to stand for 6 weeks; filtering; saturating the filtrate with CO,; boiling, again filtering, and evaporating to 500 c.c. The calcium isosaccharinate (170 g.) which then crystallises is decomposed by oxalic acid (Kiliani, B. 18, 631). Large crystals, v. e. sol. water, alcohol, and ether. Dextrorotatory. Does not ferment with yeast or reduce Fehling's solution.

Reactions.—1. Reduced by HI and P to the lactone of oxy-hexoic acid, and finally to CHPrMc.CO₂H. -2. Oxidised by HNO₃ to dioxy-propane tricarboxylic acid C₃H₃(OH)₂(CO₂H)₃, which is split up by heat into CO₂ and αγ-di-oxyglutaric acid CH₂(CH(OH).CO₂H)₂ (Kiliani, B. 18, 2514). 3. Phenyl cyanate at 165° forms C_3 , H_{30} N₄O₅ [181°] a white amorphous powder (Tesmer, B. 18, 2609).

Anilide C, H, NO. [165°]. Formed by heating the lactone with aniline at 115° (Sorokin, Bl. [2] 47, 168; J. pr. [2] 37, 318). Needles, v. sol, water. Decomposed by acids and alkalis

into aniline and isosaccharin.

Metasaccharinic acid C₆H₁₂O₆ i.e. CH₂(OH).CH(OH).CH(OH).CH(OH).CH₂.CO₂H. Formed, together with isosaccharinic acid, by the action of lime on a cold solution of milk-sugar, its Ca salt being contained in the mother-liquor from which calcium isosaccharinate has crystallised (Kiliani, B. 16, 2625; 18, 642). The free acid splits up at once into water and lactone .-CaA', 2aq: crusts of minute prisms, v. sl. sol. cold water .- CuA', 2aq: groups of minute green plates.

Lactone C₀H₁₀O₃. Metasaccharin. [142°]. [a]_b = -48°. Large trimetric plates; a:b:c = -624:1: 899. V. sol. cold water and alcohol, v.

sl. sol. ether. Lævorotatory.

Reactions .- 1. Reduced by HI to the lactone of oxy-n-hexoic acid.—2. Oxidised by HNO3 to tri-oxy-adipic acid .- 3. Phenyl cyanate at 165° forms C₁₁H₁₀N₁O₂, a white amorphous powder [205°-210°] (Tesmer, B. 18, 2608).

SACCHAROLACTONE v. Anhydride of Sac-

CHARIC ACID.

SACCHARONIC ACID C.H,O, i.e.

CO,H.CH(OH).CH(OH).CMe(OH).CO,H.

Formed by heating saccharin (1 pt.) with HNO. (3 pts. of S.G. 1.375) at 35°, diluting, adding CaCO₃, filtering, evaporating, and extracting with ether (Kiliani, A. 218, 361). The product so obtained is the lactonic acid; the free acid at once splits up into water and lactone.-Na.A. Formed by boiling the anhydride with Na₂CO₃Aq. Crystalline. — (NH4)2A".—CaA": gummy.

Ag₂A": flocoulent pp.

Lactonic acid C₂H₂O₃. Saccharone.

[e]_p = -6°. Formed as above. Large trimetric

HIAq converts it into a dibasic acid C.H.O. [139] crystallising from water in small prisms. and finally to a-methyl-glutaric acid. Does not reduce Fehling's solution .- NaA' aq. Formed from saccharone (2 mols.) and Na₂CO₂Aq (1 mol.). Trimetric prisms with neutral reaction.—NH₁A': crystals. Its aqueous solution is ppd. by lead

subacetate, but not by lead acetate or AgNO₂.

SACCHARUMIC ACID C₁₁H₁₈O₁₁. A product of the action of baryta on dextrose (Reichardt, Vierteljahrschrift pr. Pharm, 19, 384, 503). Yellowish-brown powder with bitter taste, v. sol water and alcohol, sl. sol. ether. Its solution becomes dark on exposure to air or on addition of alkalis. — BaH,A''. — Ba,A'' 5aq: pp. Cu,A'' 3aq: greyish-brown pp. — l'b,A''.

Pb₂C₁H₁₂O₁₁.

SACCULMIC ACID C₁₁H₁₂O₁? together with sacculmin, by boiling cane-sugar (300 g.) with H₂SO₄ (15g.) and water (420 g.) (Stein, A. 30, 84; Sestini, G. 10, 121). The vield of the two bodies is about 10 p.c. of the sugar used. Glittering black mass, sl. sol. water and alcohol, insol. ether. The alcoholic solution is red, with reddish-brown reflex. Sol. KOHAq and reppd. by acids. AgNO, gives brown amorphous $C_{44}H_{30}AgO_{16}$. BaCl₂ ppts. brown $C_{22}H_{18}BaO_8$ aq. Chlorine passed into water in which sacculmic acid or sacculmin is suspended gives yellow flocculent di-chloro-oxysacculmide C, H, Cl,O,. Di-chloro-oxy-sacculmide boiled with KOHAq forms oxysacculmic acid C₁₁H₈O₈, which is sol. water, but insol. water containing H₂SO₄. CuSO₄ gives in its aqueous solution a brown pp. of C₁₁H₃₀CuO₂₁. Bromine and water form amorphous orange C₄₁H₂₈Br₆O₂₂ (Sestini, G. 12, 292).

Sacculmin C, H30015. Formed as above. Black amorphous mass, insol. KOHAq. Reacts with chlorine water in the same way as sacculmic acid. According to Conrad and Guthzeit (B. 18, 443; 19, 2844), sacculmin and sacculmic acid are mixtures of variable composition.

SAFFLOWER v. CARTHAMIN.

SAFFRANINE (PHENO-) C18H16N4O. Phenosaffranine. The hydrochloride may be represented as $C_0H_3(NH_2) < \frac{N}{NPhCl} > C_0H_3NH_2$ (Bernthsen, B. 20, 179, 2690; cf. Andresen, B. 19, 2215; Nietzki, B. 19, 3017, 3163; Witt, B. 19, 3121), or by $C_0H_1 < N_{NCl(C_0H_1NH_2)} > C_0H_1(NH_2)[\frac{2}{1}4]$ (Witt).

Formation.-1. Formed by gently warming phenylene-p-diamine (1 mol.) with aniline (2 mols.) and K₂Cr₂O₂ (Nietzki, B. 16, 466). A blue compound C₆H₄ N_{Cl(NHPh)} C₆H₄NH₂(?) is first formed, and changes at 100° into the red saffranine (Barbier a. Vignon, Bl. [2] 48, 838 772; C. R. 105, 939). The blue compound is reduced by zine and hydrochloric acid to $C_0H_4 < NH > C_0H_2$. NH_2 , which is exidised by air to amido-phenazine. According to Nietzki, however, the blue intermediate compound is the indamine C₆H₄(NH₂).N:C₆H₄:NH₂Cl and yields di-amido-diphenylamine on reduction.—2. From benzene-azo-aniline (amido-azo-benzene) treatment with nitro-benzene, Fe, and HClAq

Properties .- Golden plates. When freshly precipitated by baryta from the sulphate it is $C_{1s}H_{1s}N_1OH$, but after frequent recrystallisation from hot water it approximates to C18H14N4 (Nietzki a. Otto, B. 21, 1590). V. sol. hot water, sol. alcohol, almost insol. ether. Conc. H2SO4 gives a green colour, changing to blue and red on dilution. Conc. HClAq gives a blue colour. NaNO, added to a solution of saffranine hydrochloride forms the diazo- compound C18H15N3Cl2, which gives a blue solution and yields $C_{11}H_{11}N_1C_{12}AuCl_2$. This diazo-compound on boiling with alcohol forms $C_{14}H_{15}N_2$, the salts of which form red aqueous solutions and dye wool and silk a bluer shade than saffranine. The base $C_{18}H_{18}N_3$ is also got by adding H.SO, till the colour is violet, then adding excess of NaNO₂ and boiling: it yields B'HNO₃, B'H₂SO₄, and a violet acctyl derivative. Alcoholic potash forms NH, and saffranol. Zinc-dust and HCl give leuco-saffranine and, on long boiling, C₁₈H₁₉N₃O [130°], crystallising from water in long needles yielding C₁₈H₁₈AcN₂O [173°] and converted by nitrous ether into C₁₈H₁₈N₂O [117°], crystallising from alcohol in needles.

Salts. — (C₁₈H₁₅N₄Cl)₂PtCl₄. — C₁₈H₁₅N₄Cl. Flat needles with green lustre, sl. sol. cold, v. sol. hot water, insol. HClAq.-B'HNOs. Almost

insol. HNO3.

Di-acetyl derivative C18H14Ac2N4.-B'HCl. Got by heating saffranine hydrochloride with Ac2O and NaOAc (Nietzki, B. 16, 468). Lustrous brown plates, forming a violet solution

in alcoholic soda.-B'HI.

Di-methyl-saffranine. The chloride of this substance C₂₀H₁₉N₄Cl is formed, together with $N_2(C_pH_NMe_p)_2$ by the action of p-nitroso-dimethyl-aniline (1 mol.) on aniline (1 mol.) in alcoholic solution at 100° (Barbier a. Vignon, C. R. 105, 672). An isomeric (?) di-methylsaffranine got by oxidising a mixture of C_cH₁(NH₁)NMe₂ and aniline yields B'₂H₂PtCl_s and B'HNO₂ (Nietzki, B. 16, 869; 19, 3163). An isomeride is formed by heating benzenc-azo-xylidine with aniline at 150° (Menton, A. 263, 837). Crystalline, forming a rose-red aqueous solution. A tetramethyl-saffranine C22H22N4 is got by oxidising di-methyl-phenylene-green mixed with aniline acctate (Bindschedler, B. 16, 867). It yields B'HCl, v. e. sol. water and B'HNO, aq.

Ethyl-saffranine C₁₈H₁₃EtN₄. Formed by boiling p-phenylene-ethyl-diamine with aniline, K₂Cr₂O₇, and dilute HOAc (Schweizer, B. 19, 150). Formed also by oxidising phenylene-pdiamine, aniline, and ethyl-aniline with K2Cr2O, and dilute HOAc (S.). The hydrochloride forms bluish-green hygroscopic crystals, sol. water and alcohol, insol. ether. Its solutions exhibit olivegreen fluorescence.-B'2H2PtCls: dark lustrous

Di-ethyl-saffranine C22H24N4. Formed by oxidising a mixture of C₈H₄(NH₂)(NEt₂) (1 mol.) and aniline (2 mols.) with K₂Cr₂O₇ (Nietzki, B. 16, 470). Formed also by oxidising a mixture of phenylene-p-diamine, aniline, and di-ethyl-aniline with K₂Cr₂O₂ (N.). The alcoholic solution is fluorescent. The hydrochloride is sol. HClAq.

(B. a. V.). -3. By oxidising a mixture of NANO, added to its solution in HClAq gives a NH(O₂H₄,NH₄[1:4]), (1 mol.) and aniline (1 mol.) greenish-blue colour due to the diazo-chloride with K₂Or₂O₃ (B.). Which forms C₂₂H₂₂N₄Ol₂PtCl₄. — B'₂H₂PtCl₅: greenish-blue colour due to the diazo-chloride which forms C₂₂H₂₂N₃Cl₂PtCl₄. — B'₂H₂PtCl₄: green needles.

Acetyl derivative C₁₈H₁Et_ACN₄. The hydrochloride is ppd. as glittering brown needles on adding NaCl to its aqueous solution.

 $-\mathbf{B'_{2}H_{2}PtCl_{5}}$

Tetra-ethyl-saffranine $C_{26}H_{32}N_4$ or

C28H21N4.OH. Formed by oxidising a mixture of phenylene-di-ethyl-p-diamine, aniline, and di-ethyl-aniline with $K_c C r_c O_7$ (N.).— $B'_2 H_c P t C l_s$. Para-saffranine $C_{20} H_{18} N_s$. Prepared by dis-solving mauveine in dilute acetic acid and boil-

ing with PbO2. NaOH is added to slight excess, and the red filtrate boiled with some powdered zinc and CaCO, and then NaCl added. Commercial saffranine contains some parasaffranine (Perkin, C. J. 35, 728).

Properties.—Red-brown pp., dissolving in

water or alcohol. It is isomeric or identical with commercial saffranine, prepared from equal molecules of tolylene p-diamine, o-toluidine, and aniline. Salts.—B'HCl.—B'HNO3. These salts dye silk a shade more scarlet than saffranine.

Saffranine C21H20N4 or C21H21N4OH. Formed from o-toluidine by treatment with nitrous acid and oxidation of the product with K2Cr2O7 (Mène, C. N. 25, 215; Hofmann a. Geyger, B. 5, 526; Dale a. Schorlemmer, C. J. 35, 683). Obtained by heating toluene-azo-o-toluidine with o-toluidine hydrochloride at 150°-160° (Witt, B. 10, 873), and by adding K₂CrO₁ to a hot solution of tolylene-p-diamine hydrochloride (1 mol.) and o- or p-toluidine hydrochloride (2 mols.) (Witt, B. 12, 939; Bindschedler, B. 13; 207). The commercial saffranine (saffranine hydrochloride) can be purified by recrystallisation from water containing HCl, or by treatment with alcohol (Böttger, N. R. P. 23, 181). Reddish-brown crystals, v. sol. water and alcohol, insol. ether. Conc. IICl changes the colour of its solution through violet to blue. H2SO4 turns it blue and finally green. Decolourised by zinc and HClAq. Saffranine is also decolourised by glucose and NaOHAq on heating, and hence may be used as a test for sugar in urine (Crismer, C. C. 1888, 1510); the colour is restored by atmospheric oxidation. Commercial saffranine (.5 g.) is fatal when administered to dogs by subcutaneous injection (Weyl, B. 21, 2191).—B'HCl. Thin reddish crystals, sol. water and alcohol, insol. ether and NaClAq.—B'₂H₂PtCl₂. Yellowish-red crystalline powder, almost insol. water, alcohol, and ether. —*B'HBr: minute needles.—B'HNO₃. Slender reddish-brown needles, v. sl. sol. cold water. Sulphate: needles, m. sol. water.— B'CeII,N3O7: brownish-red insoluble needles.

Substances of the saffranine class are formed by heating NH(C₀H₁NH₂)₂ with (4,3,1)- and (4,2,1)- xylidine and with (5,4,2,1)-cumidine, but not with mesidine, (5,4,3,1)-cumidine, or (5,2,1)-, (6,2,1)-, (5,3,1)-, and (3,2,1)-xylidine (Nietzki, B. 19, 3163).

Saffranol C₁₈H₁₆N₂(OH)₂. Formed by boiling saffranine hydrochloride with alcoholic potash for 8 days (Nietzki a. Otto, B. 21, 1593). Ppd. as yellowish needles by adding HCl to its solution in alkalis. Nearly insol. water, alcohol, and HOAc. Conc. H₂SO₄ forms a brown solution. Yields a crystalline diacetyl derivative.

SAFFRON. The dried stigmas of Crocus sativus, used as a colouring matter. It contains erocin (q, v), erocose (q, v), picrocrocin (q, v), polychroite, and an oil $C_{10}H_{11}O$ (209°) miscible with alcohol and ether but decomposed by water (Quadrat, J. pr. 56, 68; Weiss, J. pr. 101, 65).

Polychroite C48H60O18. Dried saffron is washed with ether and extracted with water. The extract is mixed with alcohol and filtered, and the filtrate ppd. by ether. Orange deliquescent mass, v. sol. water, insol. alcohol. Yields glucose on boiling with dilute acids.

SAFROLE C10H10O2 i.e.

CH₂ CO.C.CH:CH O.C.CH:C.CH.CH:CH₂ . Shikimole. [8°]. (232°). S.G. 18 1 0956 (S.); 113 1 0963 (Gladstone, C. J. 59, 290). V.D. 81 (obs. and calc.), $\mu_{\rm D} = 1\text{-}539$ at 11° (d.), $R_{\infty} = 45\text{-}57$ (Brühl, B. 21, 477). H.C.v. 1,243,800. H.C.p. 1,244,700. H.F. 40,300 (Stohmann a. Langbein, J. pr. [2] 46, 533). The chief constituent of the essential oil of sassafras (Sassafras officinalis) (Grimaux a. Ruotte, A. 152, 88; J. Schiff, B. 17, 1935; Poleck, B. 17, 1940; 19, 1094; 22, 2861). Occurs also in the oil obtained from the leaves and fruit of *Illicium religiosum* (Eykman, R. T. C. 4, 36, 45; B. 22, 2757; 23, 864), and in the oil of the camphor tree, Cinnamomum camphora (Flückiger, Ph. [3] 17, 989). Monoclinic crystals, sol. alcohol and ether. Smells like oil of sassafras. Inactive to light. Oxidised by dilute KMnO4 to CO2, formic, oxalic, and piperonylic acids, and piperonal. potash converts it into isosafrole. Alcoholic react with hydroxylamine or BzCl. Does not combine with NaHSO₃. Brom C₁₀H₃Br₅O₂ [170°] S. (chloroform) 7. Bromine forms

Isosafrole C; H10O2 i.e.

 $CH_2 < {}_{O} > C_6H_3.CH:CH.CH_3.$ (247°). V.D. 80·3

(obs.); 81 (calc.). H.C.v. 1,233,600. H.C.p. 1,234,500. H.F. 50,500. Formed by boiling safraje (100 g.) with KOH (250 g.) in alcohol (500 c.c. of 94 p.c.) for 24 hours (Schiff; Ciamician a. Silber, B. 23, 1160). Liquid, even at -18°, miscible with alcohol, ether, HOAc, and benzene, insol. water and alkalis. Conc. H₂SO₄ forms an intensely red solution. Oxidised by K₂Cr₂O₇ and H.SO, to piperonal and acetic aldehyde. Alkaline KMnO, gives piperonylic acid. Bromine in CS₂ forms C₁₀Br₃H₉O₂ [110°], crystallising from ligroin in colourless needles. Sodium reduces it in alcohol solution to C₁₀H₁₂O₂

C_eH₃Pr COCH₂ (228°), a liquid miscible with

alcohol and ether. Isosafrole is converted by treatment with KOH and MeOH into a compound, apparently different from methyleugenol, but yielding isovanillic acid on oxidation, and [4:2:1] CsH3(CsH5)(OAc)2 on treatment with Ac O (Ciamician a. Silber, B. 25, 1470).

Nitrosite C₁₀H₃N₂O₄ i.e. CH₂O₂:C₆H₂,C — CMe ? (Angeli, B. 24, 3994; N.O.O.N

25, 1956). Mol. w. 224 (by Raoult's method). [124°]. Ac O forms a white modification [124°]. Alcoholic potash forms an isomeride [185°] which yields a mono-acetyl derivative [129°],

it to piperonylic acid. Reduced by tin and HClAq to C₁₀H₈N₂O₈ or CH₂O₈:C₆H₃.C.—CMe ? Mol. w. 197 (by Raoult's method). Zinc and HOAc yield C₁₀H₁₀O₂, probably represented by (CH₂O₂)C₆H₂,CH₂,CO.CH, [38°], which yields a phenyl-hydrazide C₁₀H₁₀O₂(N₂HPh) [37°]. Another product of the action of zinc and HOAo is C_mH₁₈N₂O₄ [180°]; and a third is O₁₀H₁₆N₂O₄ or CH₂O₂: O₄H₁.C_—CMe ? [159°], which

yields a di-acetyl derivative [138°].

SAGAPENUM. A gum resin imported from Egypt and Persia, consisting of yellow agglomerated granules, smelling like garlic and having an acrid bitter taste. Softens in the hand. Yields umbelliferone on distillation. HNO, forms styphnic acid. Potash-fusion forms resorcin (Brandes, N. Tr. 2, 2, 97; Pelletier, Bull. Pharm. 3, 481; Johnston, Tr. 1840, 361). After moistening with alcohol it dissolves in H₂SO₄, forming a brown liquid. Sagapenum is only partially soluble in alcohol and ether, but the ethereal extract is not clouded by addition of alcohol. FeCl, colours its solutions black (Hirschsohn, J. 1875, 859; Ar. Ph. [3] 10, 481; 11, 54, 152, 247, 312, 434; C. C. 1877, 182)

SAGE OIL. Obtained in the south of Europe by distilling sage (Salvia officinalis) with water, the plant being cut down in the autumn (M. M. P. Muir, C. J. 33, 292; 37, 678; cf. Rochleder, A. 44, 4; Herberger, R. P. 34, 138; Hlasiwetz, J. pr. 51, 355). Contains a terpene (156°), salviol (q. v.), C₁₀H₁₅O (c. 200°), a camphor CleHisO, probably a little cymene, and, especially when prepared from English plants, cedrene, C₁₅H₂₄ (c. 260°). The amount of salviol and of camphor is very small at first and increases with the age of the oil, being formed by oxida-tion of the terpenes. Pure salviol, pure sage terpene, and pure codrene do not resinify when singly exposed to heat and light; but a mixture

of these rapidly darkens.

SAGO. Balls of starch got from the pith of certain species of Sagus and Cycas by stirring with water, allowing to settle, and rubbing the deposit through sieves.

SALAMANDRINE C3, Hc0N2O5. An alkaloid obtained from the poisonous secretion of the cutaneous glands of the salamander (Salamandra maculata). Crystalline, v. sol. water and alcohol (Zalesky, Bl. [2] 6, 344). Alkaline in reaction. Poisonous.—B'H.Cl.: needles.

Featurn. Poisonous.—B In Dr.; needles.

SALICIN C₁₃H₁₀O, i.e.
C.H₁₁O, O.C.H₁CH_OH. Mol. w. 286. [201²]
(Schiff, B. 14, 304). S. 3·3 at 11° (Piria, A. 96, 378). [a]₀ = -62·6° (Tiemann, B. 18, 1600; cf. Hesse, A. 176, 116; Sorokin, J. pr. [2] 37, 331). Occurs in the bark of several species of willow and poplar, e.g. Salix helix, S. amygdalina, Populus tremula, P. graca (Leroux, A. Ch. [2] 43, 440; Bruconnot, A. Ch. [2] 44, 296; Pelouze a. Gay-Lussac, A. Ch. [2] 44, 220; 48, 111; Piria, A. Ch. [2] 65, 281; [3] 1 , 257; Bouchardat, C. R. 18, 299; 19, 602, 1179; 20, 610, 1635; Gerhardt, A. Ch. [3] 7, 215; Tischhauser, A. 7, 280). Occurs also in castoreum (Wöhler, A. 67, 360).

Formation. -1. By digesting an aqueous solution of helicin with sodium-amalgam (Lisenko, and a benzoyl derivative [146°]. KMnO, oxidises Z. 1864, 577) or with zinc and H.SO. (Michael, Am. 5, 172).-2. By boiling populin with lime-

water (Piria).

Preparation .- Willow bark (6 lbs.) is boiled with water; the filtrate evaporated (to 18 lbs.); mixed while hot with PbO (2 lbs.); digested for 24 hours and filtered; the filtrate evaporated to a syrup and left to crystallise (Duflos, A. 8, 200; of. Peschier, A. Ch. [2] 44, 418; Erdmann, B. J. **8**3, 1, 136).

Properties .- Trimetric tables;

a:b:c='927:1:2'494. Sol. water and alcohol, insol. ether. Lævorotatory. Tastes bitter. Neutral to litmus. Its solutions are not ppd. by lead acetate or subacetate, by gelatin, or by tannin. Cono. H.SO, gives a red colour. IClAq forms a crystalline body (Stenhouse, C. J. 17, 827). After injection of salicin, salicylic aldehyde and salicylic acid are found in the urino (Laveran a. Millon, A. Ch. [3] 13, 145; Ranke,

Reactions .- 1. Decomposed at 240° into saliretin and glucosan.-2. Split up by emulsin and saliva at 40° into glucose and saligenin (Piria; Städeler, J. pr. 72, 350).-3. Boiling dilute H.SO, forms glucose and saliretin. -4. Oxidised by chromic acid mixture to CO, formic acid, and salicylic aldehyde.—5. Cold dilute HNO₃ forms helicin. Hot conc. HNO₃ forms picric acid.—6. Potash-fusion forms salicylic acid.—7. Boiling NaOHAq forms saliretin.—8. HCl and KClO, give tetra-chloroquinone.

Metallic derivatives.—C₁₃H₁₂NaO,

Formed from salicin and NaOEt in alcohol (Perkin, C. N. 18, 110). Crystalline.—Pb₂C₁H₁,0. Got by adding NH₃Aq to a hot cone, solution of salicin, and then adding lead subacetate. Bulky white pp.

Acetyl derivative C13H11Ac,O2. Needles (from alcohol), nearly insol. water (Schiff, Z. [2]

Bensoyl derivative C₂₀H₂₂O₃ i.e. C₁₅H₁,B2O₃. Populin. [180°]. S. ·05 at 9° (Piria); ·04 at 15°; ·24 at 100° (Schiff); S. (alcohol) 1 at 16°. Occurs in the bark and course the arms (Darwher Heaville). (alconol) 1 at 10. General in the bank and leaves of the aspen (Populus tremula) (Braconot, A. Ch. [2] 44, 296; Piria, A. Ch. [3] 34, 278; 44, 366; A. 81, 245). Formed by heating salicin with Bz₂O (Schiff, A. 154, 5). Prepared by boiling the leaves of the aspen with water. ppg. with lead subacetate, removing lead from the filtrate by H.S. and evaporating to crystalthe filtrate by H.S. and evaporating to crystallisation. Light silky needles (containing 2aq).

Tastes sweet. Lavorotatory (Biot. a. Pasteur, C.R. 34, 607). Sl. sol. water and alcohol, nearly insol. ether. K.Cr.Q. and H.SQ. forms alicylic aldehyde. HNO₃ (S.G. 1.3) forms benzoylhelicin. Conc. H.SQ. forms a deep-red solution, the containing the cont whence water ppts. a red powder ('rutilin'). Boiling dilute acids split it up into glucose, benzoic acid, and saliretin. Alcoholic NH, at 100° forms benzamide, benzoic ether, and salicin. Populin is not hydrolysed by emulsin.

Di-benzoyl derivative C₁₃H₁₆Bz₂O₂. Formed, together with the mono- and tetrabenzoyl derivatives, by heating salicin with Bz₂O (Schiff). Flocculent mass, nearly insol. water, sl. sol. ether.

Tetra-bensoyl derivative C₁₃H₁₁Bz₁O₂.

Amorphous resin, not coloured by cold H₂SO₄.

Chlore-salicin C₁₃H₁₁ClO₇. Formed by passing Cl into water in which salicin is suspended

(Piria, A. Ch. [3] 14, 275). Long silky needlet (containing 2aq), sol. water and alcohol, insolether. Tastes bitter. Resolved by emulsin into glucose and chloro-saligenin. Yields a tetraacetyl derivative, crystallising from alcohol in prisms.

and the second of the second o

Di-chloro-salicin $C_{13}H_{16}C_{12}O_7$. Formed by the action of Cl on chloro-salicin. Silky needles (containing aq), nearly insol. cold water, m. sol. alcohol. Gives no colour with FeCl, or H2SO4. Split up by emulsin into glucose and di-chloro-

saligenin. Tri-chloro-salicin C,3H,5Cl3O,. Formed by chlorinating the preceding body in presence of water and CaCo₃. Yellowish needles (containing aq) (from dilute alcohol), almost insol. cold water.

Bromo-salicin C15H17BrO7. [160°]. Formed by slowly adding Br to salicin (1 pt.) in water (20 pts.) (O. Schmidt, Z. [2] 1, 320). Four-sided prisms, v. sol. water and alcohol. Split up by

emulsin into glucose and bromosaligenin. The radicle o-oxy-benzoyl SALICYL.

[1:2]C_cH₄(OH).CO. The same name is sometimes applied to the radicle o-carboxyl-phenyl [1:2]CO_cH_cC_cH₄ and, rarely, to o-oxy-benzyl C_cH₄(OH).CH₂.

SALIGYLAMIC ACID. An old name for

o-Amido-Benzoic acid.

SALICYLAMIDE. The amide of o-Oxy-BENZOIC ACID.

SALICYLAMINE. A name for o-Oxy-BENZYL.

SALICYL-GLYCIDIC ACID v. OXY-PHENYL-GLYCIDIC ACID.

SALICYL-GLYCOLLIC ACID is o-CARBOXY-PHENOXY-ACETIC ACID.

SALICYLIC ACID v. o-OXY-BENZOIC ACID. Homosalicylic acid v. Oxy-TOLUIC ACID.

SALICYLIC ALDEHYDE v. o-OXY-BENZOIC ALDEHYDE.

SALICYL-LACTIC ACID v. DI-OXY-PHENYL-PROPIONIC ACID.

SALICYL-PHENOL v. DI-OXY-BENZOPHENONE. SALICYL-RESORCIN v. TRI-OXY-BENZOPHEN-

SALICYL-SULPHURIC ACID v. CARBOXY-PHENYL SULPHURIC ACID.

SALIGENIN v. o-OXY-BENZYL ALCOHOL. SALIGENOL. Another name for o-Oxy-BENZYL ALCOHOL.

SALIRETIN v. o-Oxy-BENZYL ALCOHOL.

SALOL v. Phenyl ether of o-Oxy-BENZOIC ACID.

SALT-FORMING OXIDES. Oxides which form salts, either by reacting with acids (or acidic oxides)—in which case the oxides are basic-or by reacting with basic oxides or hydroxides—in which case the oxides are acidic. For a table showing the compositions and general characters of the characteristic highest saltforming oxides of each group of elements, v. vol. M. M. P. M. iii. p. 661. M. M. P. M. SALTPETRE. A common name for potassium

nitrate; v. vol. iii. p. 514.

SALTS. The earliest use of the word salt seems to have been to designate the solid obtained by evaporating sea-water. The term was afterwards applied to solids which more or less resembled sea-salt, especially to those solid bodies which were easily soluble in water. The SALTS. 425

study of the compositions of salt-like substances led to the view that they were made up of two parts, one of which was electro-positive with regard to the other. When the compositions of acids had been generalised in the statement that acids are compounds of hydrogen with non-metallic, or negative, elements, the relation of salts to acids was indicated by calling salts metallic derivatives of acids. This conception of the composition of salts included the older view, inasmuch as the metallic derivative of an acid is necessarily a compound of a positive metal with a less positive non-metal, or with a (less positive) group of elements, which non-metal, or group of elements, was combined with hydrogen in the parent acid.

The most general conception of the composition of salts is that which formulates them as M.R., where M is the positive, or basic, or basylous part, and R is the negative, or acidic, or chlorous part of the salt. Both M and I may be either simple or complex. Common salt, NaCl, is the type of all salts as regards composition; the positive radicle, Na, may be replaced by other metals, or by groups of elements which are positive with regard to the other part of the compound; so the negative radicle Cl may be replaced by other non-metals, or by groups of elements which are negative with regard to the other part of the compound.

When an aqueous solution of a salt is electrolysed, the positive radicle is separated at the negative electrode, and the negative radicle at the positive electrode (secondary reactions may occur). An element may form part of the positive radicle of a salt, and the same element may form part of the negative radicle of another salt. Thus in the electrolysis of a ferric salt the iron travels to the cathode, but in the electrolysis of K, Fe(CN), the iron travels, with the cyanogen, to the anode. In the electrolysis of PtCl, the Pt is separated at the negative electrode, but in the electrolysis of Na,PtCl, the Rt is separated, with the Cl. at the positive electrode. We must then regard the radicles of, say. FeCl,, as Fe and 3Cl, the radicles of PtCl, as Pt and 4Cl, and the radicles of NaCl as Na and Cl; but we must look on the radicles of K₄Fc(CN), as 4K and Fe(CN), and the radicles of Na₂PtCl₅, not as 2Na, Pt, and 6Cl, but as 2Na and PtCl_s. Again, neither the salt K,Fe(CN)_s, nor the salt Na₂PtCl_s, in aqueous solution, gives the ordinary reactions of iron or platinum; but if these salts were composed of the radicles 4K, Fe, and 6CN, and 2Na, Pt, and 6Cl respectively, we should expect them to show the same qualitative reactions as solutions of FeCl, and PtCl. In contrast with these salts is the compound formed by evaporating a mixture of K2SO4Aq and CuSO4Aq. The salt thus produced, K.SO. CuSO. 6H.O. when dissolved in water, gives the ordinary reactions of sulphates, of K compounds, and of Cu compounds; moreover, on electrolysis the K and Cu appear at the cathode, and the group SO, is set free at the anode (where it reacts with H,O to give H,SO, and O).

But all these salts—NaCl, PtOl₄, FeCl₂, K_{*}Fe(CN)₈, Na,PtOl₂, and CuSO₄-K₈SO₄—are represented, as regards composition, by the general formula M_{*}R_{**}. This formula satisfactorily ax-

presses the composition of all salts; but it says nothing about the properties of these compounds. When solutions of two salts are mixed, a more or less complete interchange of positive radicles generally takes place. This capability of reacting as if they were composed of two parts—or, one may say, of reacting in a binary way—is characteristic of salts. Salts in solution are most probably dissociated into two parts, each of which carries an electric charge. Even if the whole of the salt is not dissociated, the portion which readily takes part in chemical changes is most probably dissociated binarily (cf. Electrical methods, p. 184).

Salts, then, may be regarded as compounds of the form M.Rv, which readily exchange M and R with other compounds of similar composition, and which in aqueous solutions are wholly or partially separated into their positive and negative radicles, each radicle carrying with it

an electric charge.

Salts are often classified as normal, acid, basic, and double salts.

An acid salt is one whose negative radicle contains hydrogen that can be eliminated by causing the salt to react with an alkali or basic oxide, while a normal salt contains no replaceable hydrogen. As an acid is described as a compound containing hydrogen, all or part of which is replaceable by metal when the acid interacts with a metal or a basic oxide, it is evident that an acid salt comes under the description of an acid, and, strictly speaking, is an acid. According to the meaning already given to the term 'salt,' the class of salts includes acids. It is, however, convenient to give a special name to the compounds of hydrogen with negative radicles. A basic salt contains a positive radicle or radicles which can be replaced by a negative radicle with formation of a normal salt. This positive radicle is sometimes the group OH, sometimes it is a group MzOy, where M is the metal of the salt. Thus Bi(OH),NO₃ and Pb(PbO)NO₃ are basic salts. When treated with nitric acid the former gives the normal salt Bi(NO₃)₃, and the latter the normal salt Pb(NO₃)₂. The basic salt is an intermediate stage between the base and the normal salt, just as the acid salt is an intermediate stage between the acid and the normal salt.

Basic salts are formed by fairly weak bases; the very strong bases, Na₂O, K₂O, CaO, &c., do not form basic salts.

Normal salts frequently combine with other normal salts to form double salts. Generally speaking, one of the components of a double salt is a salt of a strong base which forms acid salts but not basic salts, and the other component is a salt of a weaker base which readily forms basic salts but does not form acid salts. That component which is itself the salt of a strong base—e.g. K₂SO₄, NaCl, &c.—may be regarded as the more acidic or negative radicle of the double salt, while the component which is itself the salt of a weaker base-e.g. Al2(SO4)4, Zn_s(PO₄)₂, &c.—may be regarded as the more basic or positive radicle of the double salt. The double salt belongs to the type MzRy; both M and R are themselves salts. And just as many normal salts are formed by the direct union of their radicles-e.g. NaCl by combining Na and Cl. BaSO, by combining BaO and SO,—so double saits are formed by the union of a more positive with a less positive radicle, which is, in such cases, itself a sait.

The reactions of some double salts indicate that these salts are to be regarded as composed of the two simple salts which were brought together when the double salts were formed; the salt MgSO, K.SO, Gaq, for instance, gives, in solution, the reaction of sulphates, of Mg, and of K, and on electrolysis the Mg and K go to the negative electrode. On the other hand, the re-actions of some double salts indicate that these salts are not to be regarded as composed of the simple salts by the union of which the double salts were formed; the salt Cr2(C2O4)3.K2C2O4, for instance, does not give the reactions salt must be looked on as the potassium salt of the acid $H_2Cr_2(C_2O_4)$. If the salt $(NH_4)_2Cr_2(C_2O_4)_2H_2O$ is treated with NH_3Aq , a new salt is formed having the composition $Cr_2(C_2O_4)$. $(NH_4)_2C_2O_4$.4NH₃.xH₂O, and the reactions of this salt show that it is an oxalate, and therefore that it has a different constitution from that of the salt (NH₂), Cr₂(C₂O₂), from which it is obtained.

The salts of the haloid acids combine to form many double salts, e.g. PbI2.KI, BiCl3.3KCl, AuCl. KCl, &c. Most of these double haloids are generally regarded as double salts in the usual acceptation of the term; but several of them do not give the ordinary reactions of the less positive metal they contain, nor the reactions of the halogen which enters into their composition. For instance, PtCl, 2NaClAq reacts with two equivalents of AgNO₃ to give PtCl, 2AgCl; if PtCl, 2NaCl were a double salt, reacting in solution as if it were composed of the two radicles PtCl, and NaCl, it would interact with six equivalents of AgNO₃, and the products would be Pt(NO₃), NaNO₃, and AgCl. It is evident, then, that the Na-Pt chloride is the Na salt of the acid H₂PtCl_s, and that the constitu-tion of this salt is similar to that of the ordinary simple salts.

Remsen (Am. 11, No. 5 [1889]) proposes to regard all the so-called double haloids as simple salts similar to ordinary oxysalts. It seems to me that the constitutions of these salts cannot be determined by an examination of their composition only, but that the reactions of each salt must be examined. Some of the double haloids are undoubtedly simple salts, as some of the double oxysalts are certainly simple salts of metal-containing acids; but as some oxysalts containing two metals react so as to show that they are composed of two radicles, each of which is a simple salt, so some of the double haloids also give the ordinary reactions of both the metals, and also of the acidic radicle, which they contain, and must therefore be regarded as true

double salts. M. M. P. M. SALVIOL $C_{10}H_{18}O$. (200°). S.G. 12 938. $\mu_D=1^{\circ}462$ at 20°. R_{∞} 74°2. (M. M. P. Muir, C. J. 38, 292; 37, 683). A constituent of oil of Sace (q,v). It is a dextrorotatory liquid. On distillation some of it splits up into H_2O and $C_{10}H_{10}$.

Reactions.—1. Chromic acid mixture or cilute nitric soid produces acetic and oxalic

acids and camphor [174].—2. P₂O₂ produces polymerides of C₁₀H₁₆, a terpene (171°), an aromatic hydrocarbon (c. 130°), and a paraffinlike hydrocarbon (170°–180°). Cymene is not formed. Hence salviol is not C₁₀H₁₀O. However, according to Semmler (B. 25, 3350), salviol is identical with tanacetone.

Light of London Company

Constitution.—Refractive index appears to indicate absence of C:C groups.

SALYLIC ACID. A name given by Kolbe to a supposed isomeride of benzoic acid got from salicylic acid by successive treatment with PCl, and sodium-amalgam. It is identical with benzoic acid (Reichenbach a. Beilstein, A. 132, 309). The name is also applied by Städeler (A. Suppl. 7, 159) to two acids: (a) C₁, H₁, O₂ [101°] and (β) C₂, H₂₂O₃ [95°], obtained by allowing salicylic aldehyde to stand for 12 years under water. The (a)- acid forms small four-sided prisms, gives no colour with FeCl₃, and yields 'Ag, A''. The (β)- acid forms aggregates of needles, gives an intense violet colour with FeCl₃, and yields Ag₃A'''. Both acids are v. sol. alcohol and ether.

SAMARIUM. This name was given by Lecoq de Boisbaudran (C. R. 88, 322; 89, 212) to the metal of an earth which he separated from what was then known as didymia, occurring in samarskite. Delafontaine (C. R. 89, 632) obtained from didymia an earth which he called decipia, and when this had been removed by ppn. as sulphate, the new earth, samaria, remained in solution, and was obtained by fractionally ppg. by NH, Aq. Cleve (C. J. 43, 362) separated what he regarded as pure samaria from orthite; he prepared and described several salts of the new element. Cleve found the at. wt. of Sm to be 150, supposing the oxide to be Sm.O.; this number was confirmed by Bettendorff (A. 263, 164). It is still very doubtful whether samaria is a homogeneous substance; according to Crookes, it contains at least four different bodies (v. METALS, RARE, vol. iii. p. 244). Because of the great uncertainty attaching to the homogeneous nature of the so-called samaria it does not seem desirable to give an account of the bodies which have been described as compounds of Sm. The student is referred to the memoirs cited above, and also to the following:-L. de Boisbaudran, C. R. 114, 575; 116, 611 (spectrum and compounds of samaria); Marignae, Ar. Sc. [3] 3, 413 (spectrum, and compounds); Krüss a. Nilson, B. 20, 2134; 21, 2310 (spectrum); v. also, for spectrum, B. A. 1884. 438. The compounds of the supposed element are described by Cleve (l.c., and also Bl. [2] 43, 162) (cf. also Earths, vol. ii. p. 422). M. M. P. M. EARTHS, vol. ii. p. 422).

SANDAL WOOD. A dye wood furnished by Pterocarpus santalinus, which grows in tropical Asia. It dyes mordanted cotton red. It contains santalin (Meier, A. 72, 320). Yellow sandal wood (from Santalum album), yields by steam-distillation an oil containing santalol C₁₈H₁₀O, and santalal C₁₈H₂₀O (Chapoteaut, Bl. [2] 37, 303). After treatment with Na the oil yields a terpene C₁₈H₁₈, S.G. 919, $\mu_{\rm A}=1.487$ (Gladstone, C. J. [2] 10, 6). The crude oil heated in sealed tubes at 810° forms C₁₈H₂₀O (c. 840°), C₁₈H₂₀O (250°) and C₂₈H₂₀O (240°) whence P₂O₂ forms C₁₈H₁₄ (c. 177°).

and the state of t

Santalol (310°) is converted by P₂O₃ into water and C₃₅H₂₄ (260°). HOAc at 150° forms the acetyl derivative C₁₅H₂₅OAc (298°), and a compound C₃₅H₄₆O (288°).

Santalal (300°) is converted by P2Os into

C18H22 (248°).

Sandal wood oil from Santalum Preissianum contains a crystalline solid [105°] (Ph. [3] 22, 828)

SANDARACH. A gum resin which exudes from Thuja articulata growing in Barbary, and from various species of Callitris growing in Australia and New Zealand (Johnston, J. pr. 17, 157; Maiden, Ph. [3] 20, 562). Transparent yellowish mass with vitreous fracture, resembling pine-resin in taste and smell. Sol. alcohol. Completely sol. ether. Its alcoholic solution is ppd. by Pb(OAc)₂. It appears to contain several resins (e.g. $C_{40}H_{62}O_6$, $C_{40}H_{62}O_6$, and $C_{40}H_{60}O_6$) differing in solubility in alcohol.

SANGUINARINE C₁,H₁₅NO₄ (E. Schmidt, Ar. Ph. [3] 26, 622). Prepared from the root of Sanguinaria canadensis (Dana, Annals of the Lyceum of New York, 2, 245; Probst, A. 29, 120; 31, 241; Schiel, A. 43, 233; Am. S. [2] 10, 220; Naschold, J. pr. 106, 385). According to Probst and Schiel it is identical with chelerythrine, but Naschold and Schmidt assign the formula C1: II 15 NO, to sanguinarine and C₁₈H₁₇NO₄ to chelerythrine. Prepared by exhausting the root with ether and ppg. the hydrochloride by HCl. Pearly grains, insol. water, sol. alcohol and ether. Poisonous.— Salts: B'HCl aq.—B'2H_PtCle (dried at 100°).— B'2H_PtCye. According to König (C. C. 1891, i. 321) sanguinarine has the formula CanH15NO4, crystallises with aq, melts at 211°, and forms the red sults B'HCl 5aq, B'HNO, aq, B'HAuCl, and B'2H2PtCl6.

SANTAL C. H.O. Obtained from sandal wood by extracting with very dilute KOH, ppg. with HCl, and extracting the pp. with ether (Weidel, Z. [2] 6, 83). It is accompanied by a scarlet crystalline powder C14H12O4? Santal crystallises from alcohol in colourless iridescent four-sided laminæ (containing 1 aq), insol. water, sl. sol. cold alcohol, sol. KOHAq, sl. sol. NH, Aq. FeCl, colours its alcoholic solution dark red. Potash-fusion yields protocatechuic

acid. **SANTALIN** $C_{15}H_{14}O_{4}$ (Meier, A. 72, 320); $C_{15}H_{16}O_{5}$ (Wegermann a. Hüffely, A. 74, 226); $C_{17}H_{16}O_{6}$ (Franchimont, B. 12, 14). [105°]. The colouring matter of sandal wood and of coliatur wood. Extracted by ether or alcohol, and purified by ppg. its alcoholic solution with Pb(OAc), and decomposing the pp. by dilute H.SO. Minute red prisms (M.) or amorphous (F.), without taste or smell, insol. water. Its alcoholic solution is blood-red. Sol. alkalis, forming violet solutions in which BaCl, ppts. Ba(Cl, H, O,), as a dark-violet amorphous pp. Pb(OAo), added to its alcoholic solution ppts. PbCl, H, O, (dried at 100°). On heating with HCl, santalin gives off McCl (1 mol.). Gives resorcin and HOAc on fusion with potash. KMnO, gives off an odour of yanilla.

BANTONIC ACID C15H20O4 i.e. C.H. CHMe.CH(OH).CH,.CO,.H (?) (Canpizzaro, B. 18, 2748). [171°] (Hvoslef, B. 6, 1471).

S. 56 at 17°. $[a]_n = -74°$ at 20° in chloroform (Nasini, B. 13, 2210; G. 13, 164). Formed by boiling santonin with baryta-water (Cannizzaro a. Sestini, G. 3, 241; Hesse, B. 6, 1280). Colourless trimetric plates (Strüver, G. 6, 849), m. sol. hot water, v. sol. ether, v. e. sol. alcohol. Acid (235°-245°) and C₁H₂I (144° at 3 mm.) (Cannizzaro a. Amato, B. 7, 1104). Boiling HIAq and P form (a)- and (β)-metasantonin. By boiling with HOAc and heating the residue it is converted into santonide and parasantonide. Sodium-amalgam yields hydrosantonic acid. Does not react with hydroxylamine. When its chloroform solution is heated with POCl. as long as HCl comes off, and a current of damp air passed through the product, there is formed PO(C₁₃H₁₈O₃Cl)₃ [98°] (Ĉannizzaro, G. 10, 459) Salts.—NaA'. Stellate groups of needles.

-BaA'2.—AgA': white pp.

Methyl ether MeA'.

(86°). Colourless needles (Cannizzaro, G. 6, 335). Ethyl ether Eth. [95°]. [a] = -45° at 26°. Trimetric crystals.

n-Propyl ether PrA'. (220° at 3 mm.). S.G. $\frac{20}{4}$ 1·125. $[a]_{D} = -40^{\circ}$ at 20°.

Isobutyl CH, PrA'. cther [a]D = -41°. Needles (Carnelutti a. Nasini, B. 13, 2208; G. 10, 530).

Allyl ether C,H,A'. [55°]. [a], = -40°. Acetyl derivative $C_{15}H_{18}AcO_4$. [140°] Got by boiling the acid for six hours with AcCl Got by boiling the acid for six nours with acid (Sestini, G. 5, 121). Prisms (from CHOL). It is accompanied by $C_{18}H_{20}O_7$ [128°].

Chloride $C_{11}H_{10}O_8$. [155°].

Bromide $C_{11}H_{10}O_8$. [145°].

Iodide $C_{11}H_{10}O_4$. [136°].

Hydrosantonic acid $C_{11}H_{10}O_4$. [170°].

Formed by reducing santonic acid with sodiumamalgam (Cannizzaro, G. 6, 341). Colourless trimetric crystals (from ether), less sol. alcohol than santonic acid. Dextrorotatory. Oxidised by Ag,O to metasantonic acid. HOAc at 150 'forms hydrosantonide C₁₅H₂₀O₃ [156°], which is reconverted into hydrosantonic acid by alcoholic potash (Cannizzaro a. Valente, G. 8, 309). AcCl converts hydrosantonic acid into acetyl-hydrosantonide C_{1.3}H_{1.9}AcO₂ [204°], which is converted by alcoholic NH₂ at 130° into hydrosantonamide C_{1.5}H_{2.0}S.NH₂ [190°]. BzCl forms benzoylhydrosantonide C_{1.5}H_{1.9}BzO₃ [157°].

Salts.-NaA' 3aq: trimetric crystals. -KA' 2aq : monoclinic crystals.

Santoninic acid C15H20O, i.e. ÇH:CH.ÇH.CHMe.ÇO CH:CH.CH.CHMe.CH.CH(OH).CH, CO2H (Cannizzaro, B. 18, 2746). Santonous acid. $a_1 = -26^{\circ}$ in alcohol at 22°. Formed by heating santonin with KOHAq (Hesse, B. 6, 1280). Trimetric tables, al. sol. cold water, m. sol. ether, v. e. sol. alcohol. Not turned yellow by light. Acid to litmus. Not coloured red by alcoholic

potash. At 120° it splits up into water and santonin; dilute H₂SO, acts in like manner. Salts.—NaA' 3½q. S. 33 in cold water, S. (90 p.c. alcohol) 25 (Lepage, J. 1876, 618). Stellate groups of needles. Lævorotatory; aj = -18° at 22°.—BaA'₂ aq.

Metasantonic acid C₁₃H₂₃O₄. [161°]. Formed

by heating silver hydrosantonate with water. Got also by distilling santonic acid at 45 mm.

by boiling santonide with KOHAq, and by the action of Na₂CO₂Aq on isosantonin. Trimetric crystals (from ether). Lesvorotatory. Its K and Na salts are very soluble.—AgA': pp., m. sol. water.

Methyl ether MeA'. [102°]. Chloride C₁₈H₁₉O₂Cl. [139°].

Parasantonic acid C15H20O4 [173°]. [a] = -99° in chloroform (Carnelutti a. Nasini G. 10, 534). Formed by boiling parasantonide with NaOHAq or HClAq. Trimetric crystals, m. sol. water and ether. Converted by AcCl, Ac₂O, or PCl, into parasantonide. Boiling HIAq and P form (a)- and (β)- metasantonin. The parasantonates are mostly v. sol. water.—BaA'2: slender needles (from water).

Methyl ether Me₂A'. [184°]. [a]_p = -109°

in chloroform at 27°.

Ethyl ether Eth'. [173°]. $[\alpha]_D = -100^\circ$ in chloroform at 20°.

n-Propyl ether PrA'. [113°]. [a] = -91°

at 26°. Colourless prisms.

Allyl ether C₃H₃A'. [149°]. [a]_D = -92°. Lævorotatory.

Photosantonic acid C15H22O5 i.e.

CH:CH.CH.CHMe.CO.H CH:CH.CH.CHMe.CH₂.CH(OH).CH₂.CO₂H [155°]. $[a]_p = -125^\circ$. Formed, as ethyl ether of the lactonic acid, by exposing a solution of santonin in 65 p.c. alcohol to direct sunlight (Sestini, Rep. ital. chim. pharm. 1865). Formed also by exposing an aqueous solution of sodium santonate to sunshine. Prepared by insolation of a 1 p.c. solution of santonin in diluted HOAc for one month (Cannizzaro a. Villavecchia, B. 18, 2750, 2859). Trimetric prisms (from alcohol). Gives off H₂O at 100°, forming the lactonic acid $C_{15}H_{20}O_4$, and then melts at 155°. V. sl. sol. water, v. sol. alcohol and ether. Lævorotatory

Salts. - (NH₄)₂A". Gaq. - BaA" aq: white amorphous pp.—CaH₂A"₂ 3aq: silky needles, sl. sol. cold water.—CaA" xaq.—Ag₂A": white pp.

Methyl ether of the lactonic acid. [57°]. Got by the action of sunshine on a solution of santonin in MeOH. Long prisms (from MeOH).

Ethyl ether of the (a)-lactonic acid $C_{11}H_{21}O_4$. [69°]. (305°). [a]_D = -118° in a 6 p.c. alcoholic solution at 14°. Got by exposing an alcoholic solution of santonin to sunlight (Sestini, J. 1876, 622). Formed also from Ag.C₁₈H₂₀O₅ and EtI (V.). Formed also by the action of alcohol and H₂SO₄ on photosantonic acid. Thin tables, almost insol. cold water, v. sol. alcohol and ether. Levorotatory. NaOH converts it into sodium photosantonate.

Ethyl ether of the (β)-lactonic acid C₁₁H₂₄O₄. [155°]. [a]_D = 77° in alcohol at 14°. Formed, together with the preceding, by insolation of a solution of santonin in absolute alcohol. Tables (from ether). Dextrorotatory.

Anhydrophotosantonic acid $C_{15}H_{20}O_4$ i.e. $C_{12}H_{18}(CO_2H)_2$. [133°]. [α]_D = +31°9. Obtained by saponification of its ether, which is formed by passing gaseous HCl into a solution of photosantonic acid in absolute alcohol (Villavecchia, B. 18, 2862). Crystalline solid. V. sol. alcohol and ether.—Bah": white amorphous solid, v. e. sol. water.

(180°-186°). ether Et,A": Di-ethyl $[a]_{p} = +20.4^{\circ}$. Colourless liquid.

Isophotosantonic acid $C_{15}H_{22}O_5$ i.e.

CH:CH.CH.CHMe.C(OH), CH:CH.CH.CHMe.CH.CH(OH).CH₂.CO₂H (?) [a]_p = 124° in a 3 p.c. alcoholic solution at 11°. Formed, together with photosantonic acid, by exposing a solution of santonin (1 kilo.) dissolved in HOAc (52 litres of S.G. 1.054) for several nionths to sunshine (Cannizzaro a. Fabris, B. 19, 2260). Thick trimetric crystals (from alcohol), sl. sol. water, m. sol. ether, v. sol. alcohol. Dextrorotatory. At 100° it gives an anhydride $C_{13}H_{20}O_4$. Sol. alkalis and hot Na₂CO₃Aq, forming orange-red solutions .- BaA'2 aq : white amorphous powder, v. e. sol. alcohol and water.

Acetyl derivative C₁₈H₂₁AcO₃.
[a]_D = 59°. Transparent needles. Dextro-

rotatory.

Di-acetyl derivative *C15H20Ac2O5. [c. 166°]. Crystals, v. sl. sol. alcohol and ether. Converted into C₁₈H₂₁AcO₈ by heating with absolute alcohol at 120°

Pyrophotosantonic acid C14H20O2 [94·5°]. Formed by heating photosantonic acid in a current of CO₂ or H₂ (Sestini a. Danesi, G. 12, 83). Got also by heating photosantonic acid with HI (Cannizzaro a. Fabris, B. 19, 2260). Crystals, sol. alcohol and ether. -BaA'2. Forms, on distillation, C13H20 (222°).

SANTONIDE $C_{1a}H_{18}O_{3}$. [127.5°]. [a]_D = 754° in chloroform at 20°; 666° in alcohol at 20°. S.V.S. 206. Formed by evaporating a solution of santonic acid in HOAc and heating the residue at 180° (Cannizzaro a. Valente; Carnelutti a. Nasini, G. 10, 528; 13, 149). Trimetric crystals. Dextrorotatory. M. sol. chloroform, v. sl. sol. alcohol. Not attacked by PCl. Boiling KOHAq forms metasantonic acid.

 $\begin{array}{cccc} \textbf{Parasantonide} & \textbf{C}_{15}\textbf{H}_{16}\textbf{O}_{3}. & [110^{\circ}]. & \textbf{S.G.} & ^{90}\\ \textbf{1} \cdot \textbf{202}. & [a]_{D} = 897^{\circ} \text{ at } 26^{\circ}. & \textbf{S.V.S.} & 206. & \textbf{Formed}\\ \textbf{by boiling santonic acid with HOAc, evaporating,} \end{array}$ and heating the residue at 260° (Cannizzaro, G. 8, 309; 10, 528). Trimetric crystals, v. sl. sol. alcohol, m. sol. Ac₂O. Not attacked by Ac₂O or PCl. Boiling KOHAq converts it into parasantonic acid.

Metasantonide. [138°]. $[a]_p = -223^\circ$ at 26°. S.V.S. 236. Prepared by heating santonin with conc. H_2SO_4 for some hours at 100° and $[a]_{D} = -223^{\circ}$ at ppg. by water (Cannizzaro a. Valente, Rend. Accad. Lincci, ii.; G. 10, 42). Crystals (from ether). Converted by Na₂CO₃Aq into metasartonic acid.

SANTONIN C15H18Os i.e. сн:сн.сн.снм**.**.со $CH:CH.CH.CHMe.CH.CH < CH_2 > CO$ or

ÇH₂.ÇMe.C.CH₂.ÇH.O -CO .CMe.C.CH₂.CH.CHMe CO (Cannizzaro). Mol. w. 246. [170°]. S.G. 12 1·247. [a]_p = -174° in alcohol of 90 v. p. c. (Hesse, A. 176, 125); = -172° in chloroform at 20°. S. 12 2 at 17·5°; •4 at 100°. S. (alcohol) 2·3 at 22·5°; 8 at 50°; 87 at 80°. S. (ether) 2·4 at 40°. S. (chloroform) 23 (Schlimpert, N. Br. Arch. 100, 151). Occurs in wormseed (semen contra, semen cinæ, or semen santonici), the undeveloped flower heads of Artemisia Vahliana and other species of Artemisia (Kahler, Brandes Archiv, 84, 818; 85,

216; Alms, ibid. 34, 319; 39, 190; H. Trommsdorff, A. 11, 190; Heldt, A. 68, 10, 40).

Preparation - From Artemisia maritima (Linn.) which contains 2 p.c. The seeds (5 pts.) are treated with lime (1 pt.) and water, and extracted with alcohol. The extract is freed from alcohol by evaporation and neutralised with HCl, when santonin crystallises out. In this process a lime- compound (C15H10O4)2Ca, is first formed, and atterwards decomposed by HCl, which forms santonic acid, $C_{13}H_{29}^{-}O_{4}$, whence santonin is formed by splitting off H_2O (Busch, $J.\ pr.$ [2] 35,

822).

Properties. — Flattened hexagonal prisms,
May be sublimed. which turn yellow in light. May be sublimed. Levorotatory, the specific rotation being but little affected by temperature or concentration of the solution (Hesse; Nasini, G. 13, 139). Nearly insol. cold water, v. sol. hot alcohol and Poisonous, exerting an anthelmintic ether. action, and producing temporary colour-blind-ness (Lavater, *Pharm. Viertelj.* 2, 110; Wells, *J. Ph.* [8] 15, 111; Martini, *C. R.* 47, 259; 50, 545). Reacts with hydroxylamine, forming an oxim (Cannizzaro, B. 18, 2746); santonin is best administered as oxim (Coppola, C. C. 1887, 1206, 1301). Not attacked by aqueous KMnO. Resinified by boiling conc. HClAq. KOH turns santonin crimson (especially in presence of alcohol) and forms $C_{1s}H_{1p}KO_4$. Accl has no action. Conc. H₂SO₄ containing FeCl₃ gives a violet colour (Lindo, C. N. 36, 222; Knapp, D. P. J. 268, 42).

Reactions .- 1. By treatment with 1 mol. of PCl, it gives a compound C15H1, ClO2[125° uncor.]. With 2 mols. of PCl₃ it gives a compound $C_{13}H_{13}Cl_{2}O$, [182° uncor.] (Pawlewski, B. 18, 2900). According to Klein (B. 26, 982) the compound is $C_{13}H_{13}Cl_{3}O_{2}$ —2. Reduced by HI and P to santonous acid C₁₅H₂₀O₃, -3. HNO₃ (S.G. 1·123) at 95° forms CO₂, succinic, oxalic, and acetic acids, and HCy (Wagner, B. 20, 1662).—4. Boiling baryta-water forms santonic acid.—5. Hot KOHAq forms santoniniò acid.—6. Potash-fusion forms formic and propionic acids (Banfi a. Chiozza, A. 91, 112).-7. An alcoholic solution exposed for some months to sunlight forms the ethyl ether of the lactonic acid of photosantonic acid (v. supra).-8. A solution in HOAc exposed to sunshine yields photo- and isophoto- santonic acids.—9. Forms santonol on distillation with zinc-dust. Distillation over red-hot zinc-dust gives di-methyl-naphthalene (Cannizzaro, G. 12, 415).—10. Cold conc. HClAq forms an isomeride C₁₃H₁₈O₂₁ [260°], sl. sol. hot alcohol, insol. water (Andreocci, B. 26, 1373). [a]_D = +112°. This body is not acted upon by hydroxylamine or phenyl-hydrazine, but yields an acetyl derivative C₁₃H₁₇AcO₃ [156°]. Like santonin it is insol. Na₂CO₃Aq, but sol. NaOHAq. It is reduced by zinc-dust and HOAc to $C_{13}H_{20}O_{3}$ [175°] [a]_D = -53.3° an acid isomeric with santonous acid, which when fused with potash yields propionic acid and di-methyl-(β)naphthol.-11. Br in glacial acetic acid forms C₁₅H₁₆O₂.HOAc,Br₂. Crystals (from alcohol), decomposing above 60°. On boiling with alcohol and aniline it yields bromo-santonin C15H17BrO3 [151°]. On boiling with KOHAq the acetate bromide yields santonin (Klein, B. 25, 3317).

Oxim C₁₈H₁₈O₂(NOH) aq. [209°] (Klein, B.

26, 411; cf. Gucci, G. 19, 867). Needles (from dilute alcohol). Ac.O yields Cl.H.,O.(NOAO) [166°] or [170°] (K.); [203°] (G.). The oxim prepared by alkaline hydroxylamine gives with HCl and FeCl, a violet-red colour [syn-oximic acid1.

Bensyl ether of the oxim [152°]. HIAq

forms benzyl iodide. Phenyl-hydrazide C15H18O2(N2HPh). [220°]. Pale-yellow needles (from alcohol), not decomposed by cold acids (Cristaldi, G. 17, 526; Grassi, C. C. 1887, 1163).

Chlorosantonin C₁₈H₁,ClO₃. Formed from santonin and chlorine-water (Heldt, A. 63, 34; Formed from Sestini, Bl. 5, 202). Crystalline. Turns yellow in light.

Di-chloro-santonin C13H16Cl2O3. Formed by passing Cl for a long time through water containing santonin in suspension (Sestini). Groups of small plates (from alcohol). Coloured orangered by alcoholic potash.

Tri-chloro-santonin C15H15Cl3O3. [213°]. Monoclinic prisms, not coloured by sunshine, m. sol. alcohol and ether.

(a). Metasantonin C₁₁H₁₁O₃, [161°]. (239°). S.V.S. 205. [a]_D=124° in chloroform at 20°. Formed, together with (β) metasantonin, by boiling santonic acid or parasantonide with HIAq and P (Cannizzaro, G. 4, 446, 452; 8, 318; 10, 401). Trimetric hemihedral plates (from ether). Dextrorotatory. Not affected by light. Yields C₁₃H₁,BrO₃ [212°] and C₁₃H₁₈Br₂O₃ [184°].

(β)-Metasantonin $C_{13}H_{18}O_3$. [136°]. S.V.S. 211. [α]_D = 124°. Formed as above. Monoclinic crystals. Yields $C_{13}H_{17}BrO_3$ [114°] and C₁₃H₁₆Br₂O₃ [186°].

Photosantonin. A name for the ethyl ether of the (a)-lactonic acid of photosantonic acid (v. supra).

SANTONOUS ACID $C_{13}H_{20}O_{3}$ i.e. $C_{10}H_{3}Me_{2}(OH).C_{2}H_{4}.CO_{2}H$? [179°]. [a]_D = 74° in alcohol at 20°. Formed by boiling santonin with HIAq and P (Cannizzaro a. Carnelutti, B. 12, 1574; G. 12, 393; 13, 385). White needles, v. e. sol. alcohol and ether, sl. sol. cold water, sol. Na CO Aq. May be distilled in vacuo. Distilled over powdered zinc in a current of hydrogen it yields di-methyl-naphthalene, dimethyl-naphthol, propylene, and a little xylene. On heating with Ba(OH)₂ above 360° it yields CO₂, CH₄, and di-methyl-naphthol C₁₂H₁₁OH [135°], which yields $C_{12}H_{11}OMe$ [68°]. Converted by heat into the anhydride of isosantonous acid, and, finally, into di-methyl-naphthol dihydride and propionic acid.

Salts .- NaA'. Needles, ppd. by adding ether to its alcoholic solution. V. sol. water .-

BaA'...—"AgA': white pp., quickly turning black.

Mathyl ether MeA'. [32°].

Ethyl ether EtA'. [117°]. [a]_b = 78° in chloroform or 67° in HOAc at 20°. White crystals, sol. alcohol and ether. Dextrorotatory. Converted by BzCl into C, H18BzEtO [78°]. Na added to its ethereal solution ppts. C₁₅H₁₈NaEtO₃, whence EtI produces C₁₅H₁₈Et₂O₃ [32°], which on saponification yields ethyl-santonous acid $O_{15}H_{19}EtO_3$ [116°], $[a]_b = +76^\circ$ in alcohol. Isosantonous acid $O_{15}H_{29}O_3$. [155°]. Formed by heating santonous acid, dissolving the re-

sulting anhydride in NaOHAq, and ppg. with

HClAq. Got also by heating santonous acid (1 pt.) with Ba(OH), (3 pts.) in a bath of molten lead (Cannizzaro a. Carnelutti, B. 12, 1574; G. 12, 400). Small plates, sl. sol. water, sol. alcohol and ether. Inactive to light. May be distilled in vacuo.

Ethyl ether EtA'. [125°]. Crystalline. BzCl at 100° yields C₁₅H₁₈BzEtO₃ [91°]. Na added to its ethereal solutions gives no pp., but on adding alcohol C₁₅H₁₅NaEtO₃ is thrown down as an amorphous powder, readily decomposed by water. The Na derivative is converted by EtI into C₁₅H₁₈Et₂O₃ [54°], whence alcoholic potash produces C₁₅H₁₉EtO₃ [143°], v. sol. alcohol and ether.

SAPONIFICATION. The conversion of the natural fats into soap (and glycerin) by boiling with alkalis. In a more general sense it is used to denote the resolution of compound ethers into acids and alcohols. In the widest sense it is used to denote the production of an acid from a neutral substance by hydrolysis.

SAPONIN $C_{32}H_{34}O_{19}$ (Rochleder, Z. [2] 3, 632); $C_{19}H_{39}O_{19}$ (Stütz, A. 218, 231); $C_{32}H_{32}O_{17}$ (Hesse, A. 261, 373). Struthiin. Githagin. Polygalin. Polygalic acid. Senegin. A glucoside occurring in the common soapwort (Saponaria officinalis) (Schrade, N. Journ. d. Chem. 8, 548), ogicinaus) (Schrade, N. Journ. d. Chem. 8, 548), in the Oriental soapwort (Gypsophila Struthium) (Bley, A. 4, 283; Bussy, A. 7, 168), in quillaja bark (O. Henry a. Boutron-Charland, J. Ph. 4, 249), in the cornockle (Agrostenna Githago) (Malapert, J. Ph. [3] 10, 339; Scharling, A. 74, 351; Christophsohn, Ar. Ph. [3] 6, 432, 461), in the root of Polygala Scriega (Bolley, A. 90, 211; 117), and in many other share. 91, 117), and in many other plants. White amorphous powder, insol. alcohol and ether, v. e. sol, water. The dilute aqueous solution froths like soap when shaken; the lather is prevented by addition of alcohol. Impure saponin produces sneezing. Saponin begins to turn black at 145° (Blyth), but does not melt or sublime when heated. Baryta forms amorphous $(O_{12}H_{20}O_{10})_2$ Ba $(OH)_2$. A solution of saponin is ppd. by lead acetate. Decomposed by boilting dilute acids into sapogenin and sugar $C_2H_{11}O_2$ $(I_{12}D=52^{\circ}$ at 25°) (Rochleder a. Schwarz, Sitz. W. 11, 339; Overbeck, N. Br. Arch. 77, 135; Schiaparelli; cf. Crawford, Pharm. Viertelj. 6, 361; Flückiger, Ph. [3] 8, 488).

Acetyl derivatives C₁₉H₂₂Ac₁O₁₀. [161°].—
C₁₉H₂₂Ac₂O₁₀. [99°].—C₁₂H₂₂Ac₂O₁₁. [137°].—
C₁₉H₂₂Ac₂O₁₂. [84°] (Stütz).—C²₂H₁₅Ac₂O₁₇.—
C₂₂H₁₄Ac₂O₁₇.—C₂₂H₁₆Ac₁₂O₁₇.—C₃₂H₄₆Ac₁₅O₂₀

Butyryl derivative $C_{19}H_{20}(C_1H_1O)_0O_{10}$ (Stütz); $C_{22}H_{43}(C_1H_1O)_1O_{17}$ (Hesse). [68°-72°]. According to Schiaparelli (G. 13, 422; Ph. [3] 14, 801), saponin obtained from soapwort has at 20°, yields amorphous $Ba_2H_2(C_{32}H_{32}O_{18})_3$, and is split up by boiling dilute H_2SO_4 into glucose and saponetin C40H86O13.

SAPOGENIN C₁₁H₂₂O₂. Formed by hydrolysis of saponin. Concentric groups of needles from alcohol), sol. ether, insol. water. From solution in dilute potash it is ppd. by cono. KOHAq as flocoulent potassium-saponin. Potash-fusion gives acetic and butyric acids and a crystalline compound [128°].

Oxysapogenin C, H22O, is obtained by the action of HClAq on a glucoside present in the alcoholic extract of Herniaria (Barth a. Herzig,

M. 10, 172).

SAPPANIN C₁₂H₁₀O₄. Formed, together with resorcin and a little pyrocatechin, by fusing extract of sapan wood with NaOH (Schreder, B. 5, 572). Crystallises from water in plates (containing 2aq), nearly insol. cold water, v. sol. alcohol and ether, insol. CHCl.. Neutral in reaction. FeCl, colours its aqueous solution red. NaOCl gives a grass-green colour. May be distilled. Pb(OAc), gives a yellowish pp. Reduces hot Fehling's solution and ammoniacal AgNO,. HNO, forms tri-nitro-resorcin (styphnic acid). Yields diphenyl on distillation with red-hot zincdust. AcCl gives $C_{12}H_cAo_4O_4$, crystallising from alcohol in prisms. Br and HOAc give $C_{12}H_bBr_bO_4$, crystallising from dilute alcohol in needles.

SAPRINE $C_3H_{16}N_{2}$. [From $\sigma\alpha\pi\rho\delta s$, putrid.] An alkaloid in putrefying flesh (Gautier, Bl. [2] 48, 13), v. Ptomaïnes.

SARCINE v. HYPOXANTHINE. SARCOLACTIC ACID v. LACTIC ACID. SARCOLEMMA v. MUSCLE.

SARCOSINE v. METHYL-AMIDO-ACETIC ACID. SARCOSINIC ACID C,H,NO2. [195°]. Occurs in a variety of shellac known as Sonora gum (Hertz, J. 1876, 912). White silky scales, v. sol. water, insol. alcohol and ether. Cannot

be sublimed. Converted by nitrous acid into lactic acid. Forms salts with acids and bases. It is a weaker acid than alanine.

SARCOSINURIC ACID v. vol. iii. p. 260. SARSAPARILLA v. PARILLIN.

SASSAFRAS OIL. Obtained by steam-distillation from the bark and wood of the root of Laurus sassafras of North America. Contains saffrole (q. v.) and a terpene C₁₀H₁₆ (156°). S.G. 9 ⋅835.

SATURATION, CAPACITY OF. When a base is added to an acid, a point is reached whereat the properties of the base are neutralised by those of the acid, and the properties of the acid are neutralised by those of the base. The compound that is produced—a salt—has neither the properties of the acid nor the properties of the base. The capacity of saturation of an acid is measured by the quantity of a base, taken in formula-weights, which must be added to the quantity of the acid expressed by its formula in order to form a normal salt. The capacity of saturation of a base is measured by the number of formula-weights of an acid which must be added to a formula-weight of the base in order to form a normal salt. The study of the capacities of saturation of acids and bases leads to the classification of acids as monobasic, dibasic, tribasic, &c., and of bases as mono-acid, di-acid, tri-acid, &c. (v. Acids, vol. i. p. 49; and Acids, Basicity of, vol. i. p. 51). The notion of equivalency also arises from the study of the capacities of saturation of acids and bases (v. vol. ii. p. 446).

When chlorine combines with potassium, one atom of the metal is saturated by one atom of the halogen; but three atoms of chlorine are required to saturate a single atom of bismuth or antimony. The notion of a definite capacity of saturation has been extended from the acids and

bases to the atoms of the elements. The development of this conception leads to the hypotheses of valency and atom-linking (3. CLASSIFICATION, vol. ii. pp. 213-215; Equivalency, vol. ii. p. 446; and FORMULE, vol. ii. p. 572). M. M. P. M.

SAVINE OIL. Oleum Sabinæ. The essential oil from Juniperus Sabina contains a sesquiterpene C₁₈H₂₄, which has a crystalline hydrochloride C₁₈H₂₄2HCl [118°] (Wallach, A. 238, 82).

SAVORY. Essence of savory (from Satureja montana) contains 40 p.c. carvacrol (232°) and two terpenes (174°) and (183°) (Haller, C. R. 94. 132). The oil from Satureja hortensis contains 20 p.c. cymene, 50 p.c. carvacrol, a terpene (179°). S.G. 15 .855, and a very small quantity of a phenol which differs from carvacrol in not being extracted by ether from its dilute alkaline solution, and yields a phosphate [69°] (Jahns, B. 15, 816).

SCAMMONY. A purgative gum-resin composed of the dried milky juice of Convolvulus scammonia and of other species of Convolvulus. It is purified by boiling with alcohol, neutralising the alkaline filtrate by dilute H2SO4, filtering, and evaporating (Perret, Bl. [2] 28, 522).

contains jalapin (q. v.).

SCANDIUM. Sc. At. w. 44. Mol. w. un-The oxide of a new element was isolated in 1879 by Nilson (B. 12, 554) from euxenite and gadolinite; the same oxide was obtained, about the same time, by Cleve, also from Scandinavian minerals (Bl. [2] 31, 486 [1879]). The name scandium was given to the metal of the new earth by Nilson to denote the locality of the minerals from which the oxide had been obtained. In his first memoir Nilson represented scandia as ScO_n and determined the at. w. of Sc to be c. 170; in his second memoir (B. 13, 1439) he adopted Cleve's correction, and formulated the oxide as Sc₂O₂, and gave the at. w. of the metal as 44. The element scandium has not yet been isolated.

Occurrence. — Sc₂O₃ is found, along with yttria, ytterbia, &c., in very small quantities in a few rare minerals-gadolinite, keilhauite, yttrotitanite, and euxenite. From 4 kilos. adolinite Cleve obtained 8 g. Sc₂O₃, and 1.2 g. Sc.O. from 3 kilos. yttrotitanite.

Preparation.—The metal has not been

isolated (v. Scandium oxide, infra).

Detection .- So salts give a very brilliant emission-spectrum, rich in rays. (B. 12, 555) gives the wave-lengths of the most characteristic lines as 6304, 6079, 6037 in the orange; 5526 in the yellow (very marked); 5031 in the green; 4415, 4400, 4374, 4325, 4326, 4314, and 4249 in the indigo (v. also B. A. 1884, 440).

Chemical relations .- Ten years before Nilson discovered So, Mendeléeff asserted that an element would be found in the group of which boron is the first member, and that this element would resemble B and Al. To this unknown element Mendeléeff gave the name ekaboron, and he stated the properties of the element and its compounds in detail. The properties of the compounds of scandium correspond with great closeness with those of Mendeléeff's ekaboron (p. tables in vol. i. p. 352; cf. vol. iii. p. 815).
The properties of ekaboron were arrived at by

comparing the properties of pairs of elements related to one another, as regards positions in the periodic arrangement, similarly to ekaboron and its atom-analogues. The relations expressed by the following scheme were specially studied by Mendeléeff:

Eb:Al = Ca:Mg = Ti:Si = V:P = Cr:S: Eb:B = Ca:Be = Ti:O = V:N = Cr:O = Mn:F.

These statements mean, the relations between the properties of Eb and Al are similar to the relations between the properties of Ca and Mg, &c. For a brief working out of similar relations in the case of eka-aluminium v. GALLIUM (vol. ii. pp. 598-9). Scandium is the second even-series member of Group III. It follows B. and is followed by Y, La, and Yb in the even series of this group. So resembles Al in many respects, but the difference between these elements is shown, among other ways, in the fact that the double sulphate of Sc and K-Sc2(SO4)3.8K2SO4-is not an alum (v. EARTHS, METALS OF THE ; vol. ii. p. 424).

Scandium, chloride of, ScCl_s(?). hygroscopic needles separate on evaporating a solution of the oxide in HClAq to a syrup; HCl is given off on heating, and an oxychloride remains as a white powder (Cleve, l.c.).

Scandium, oxide of, Sc.O. (Scandia.) Prepared by ppg. solutions of Sc salts by NH,Aq, washing the white, gelatinous, very bulky pp. of hydrated oxide, drying at 100°, and then heating strongly; also obtained by heating to redness Sc nitrate, sulphate, or oxalate. A white, light powder, resembling MgO; sol. in hot cono. H₂SO₄Aq or HNO₂Aq. S.G. 3·864 (Nilson a. Pettersson, B. 13, 1461). S.H. from 0° to 100° = 153 (N. a. P.).

Scandia is best obtained from euxenite. The finely-powdered mineral is fused with KHSO, the product is dissolved in cold water, and ppd. by NH₃Aq, the pp. is dissolved in HNO₃Aq, the solution is boiled for some time, filtered from any pp. which forms, and ppd. by oxalic acid; the ppd. oxalates are dried, heated strongly, washed with hot water to remove the K2CO3, dissolved in HNO3Aq, and the solution is evaporated to dryness and the residue heated till it melts; the fused nitrates are treated with water, when a pp. forms, consisting of oxide of Th with small quantities of oxides of Ce, U, and Fe; the filtered solution is evaporated to dryness, the nitrates are partly decomposed by heating, and then treated with water; the residue, which contains a basic nitrate of Sc, is evaporated with HNO, Aq, and the residue is again heated for some time, treated with water, and the insoluble evaporated with HNO, Aq, and so on. This process separates didymia, yttria, and terbia, the nitrates of which earths are not so readily decomposed by heat to basic nitrates as Sc nitrate is. By repeating this process 68 times Nilson (B. 13, 1442) obtained a nitrate solution which showed no absorption bands, and contained only salts of Sc and Yb. The solution of Se and Yb nitrates is evaporated with conc. H2SO4, saturated K2SO4Aq is added, the salt Sc₂(SO₄)₃.3K₂SO₄ which separates (Yb sulphate remains in solution) is dissolved in water, and ppd. by NH3Aq; the ppd. Sc2O3.xH2O is washed and dissolved in HNO, Aq, and Sc oxalate is ppd. by oxalic acid; the ppd. oxalate is washed,

A white salt, Barium selenate BaSeO₄. A white salt, obtained by decomposing an alkali selenate by BaCl2Aq, filtering, and washing. Insol. water and HNO, Aq; boiled with HClAq gives BaSeO,, which dissolves. S.G. 4.67 at 22° (Schafarik, J. 1863. 15; Michel, C. R. 106, 878).

Beryllium selenate BeSeO, 4aq. Rhombic

crystals (Topsöe, W. A. B. 66, 5).

Cadmium selenate CdSeO, 2aq. By dissolving CdO.xH2O in H2SeO4Aq, and crystallising; lustrous, rhombic plates; S.G. 3.632 (von Hauer, J. pr. 80, 214). Forms double salts with NH, and K (Topsöe, l.c.; von H., l.c.; von Gerichten, B. 6, 162).

Calcium selenate CaSeO₄, 2aq. Resembles CaSO₄; obtained by ppg. K₂SeO₄Aq by Ca(NO₂)Aq, dissolving in cold water, and ppg. by heating (von Hauer, l.c.). Also formed by fusing CaCl₂ with K₂SeO₄ and NaCl (Michel, C. R. 106, 878).

Chromium selenate. Not isolated. Double salts, which are alums, are known, of the composition Cr₂(SeO₄)₃.M₂SeO₄. 24aq (Wohlwill, A. 114, 162; Fabre, C. R. 105, 114; Pettersson, B. 6, 1466). Alums are also known of the com-

Cobalt selenate CoSeO, 7aq. Hydrated salts have been obtained with 6aq and 5aq (v. Mischerlich, P. 11, 327; Topsöe, W. A. B. 66, 5). Forms double salts with K2SeO4, and (NH4)2SeO4

(T., l.c.; von G., l.c.; von H., l.c.).

Copper selenate CuSeO, 5aq. Blue, transparent, lustrous crystals, isomorphous with the sulphate. By dissolving CuO2H2 in H2SeO4Aq (Mitscherlich, P. 11, 330). Forms double salts with selenates of NH, K (Topsöc, l.c.; von G., l.c.); also with Mg and Zn selenates (Wohlwill, l.c.).

Didymium selenate Di₂(SeO₄)₃ (Cleve, Bl. [2] 43, 362). Also with 5aq (C., l.c.); and with 6aq (Frerichs a. Smith, A. 191, 350). Forms double salts with NH, and K selenates (C., l.c.).

Iron selenate FeSeO. 7aq (Ferrous selenate). By evaporating, in H, a solution of Fe, or FeCO₃, in H₂SeO₄Aq; resembles FeSO₄. 7aq (Topsöe, *l.c.*). Obtained by Wohlwill (A. 114, 189) with 5aq. Forms a double salt with K_2SeO_4 (von G., l.c.).

Lanthanum selenate La₂(SeO₄)₃.12aq (F. a. B., l.c.).

Lead selenate PbSeO4. A white powder; by ppg. K₂SeO₄Aq by Pb(NO₂)₂Aq (Schafarik, J. 1863. 1*5*).

Magnesium selenate MgSeO, 6aq. White, monoclinic crystals; isomorphous with the sulphate; S.G. 1.928 (Topsöe, î.c.). Forms double salts with NH, and K selenates (T., l.c.; von G., l.c.).

Nickel selenate NiSeO, aq. By evaporating solution of NiCO, in H_2 SeO, Aq (Mitscherlich, l.c.; Wohlwill, l.c.). Forms double salts with selenates of NH, and K (von G., l.c.; von Hauer, J. pr. 80, 214).

Mercury selenates. 1. Mercuric selenate, HgSeO. By digesting HgO with H.SeO.Aq, or by adding excess of H.SeO.Aq to mercuric acetate, and evaporating; a yellowish-white solid. Decomposed by water, giving a basic salt HgSeO₄. 2HgO (Cameron a. Davy, Trans. I. 28, 187). 2. Mercurous selenate, Hg₂SeO₄; by ppg. HgNO, Aq by K, SeO, Aq (C. a. D., 1c.). With

NH.Aq forms (NHg.)2SeO. 2aq.

Potassium selenates. The normal salt. K2SeO4, is obtained by fusing Se, K2SeO2, or native lead selenide, with KNO, dissolving in hot water, allowing to cool partly, pouring off from excess of KNO, which separates, and colfrom excess of KNO, which separates, and collecting the crystals which separate from the mother-liquor. Equally sol. hot and cold water (Mitscherlich, P. 9, 623; 11, 327). Closely resembles K₂SO₄. The acid sall KHSeO₄ is obtained like, and closely resembles, KHSO₄ (M., l.c.). K₂SeO₄ forms many double salls; with MSO₄, M= Cd, Co, Cu, Fe, Mn, Hg, and Zn (von Gerichten, B. 6, 162); with Al₂(SeO₄); and Cr (SeO₄) the compounds being alums. and Cr₂(SeO₄)₃, the compounds being alums (von G., l.c.; Pettersson, B. 9,1559, 1676; Schröder, J. pr. [2] 22, 432; Fabre, C. R. 105, 114).

Silver selenate Ag, SeO, Similar to, and isomorphous with, Ag, SO, (Mitscherlich, Lc.).

Sodium selenate Na, SeO, Prepared like

K.ScO.; separates with 10aq when crystallised below 40° (M., l.c.).

Strontium selenate SrSeO,. Obtained by fusing SrCl₂ with NaCl and an alkali selenate: S.G. 4.23. Exactly resembles celestine in crystallographic and optical properties (Michel, C.R. 106, 878).

Thallium selenate Tl₂SeO₄. By dissolving Tl.CO, in H.SeO,Aq, and evaporating. Forms white, prismatic needles, isomorphous with K₂ScO₄; sl. sol. cold water; insol. alcohol or ether (Kuhlmann, Bl. 1864 [1] 330; Oettinger, Zeit. Chem. Pharm. 1864. 440). Forms double salts, which are alums, with Al. (SeO₄)₃ and with

Cr₂(SeO₄)₂ (Fabre, C. R. 105, 114). Zinc selenate ZnSeO₄, 7aq. Various hydrates are known (v. Mitscherlich, P. 11, 326; 12, 144; Topsöe, l.c.). Forms a double salt with Tl₂SeO₄ (Werther, Bl. 1865 [1] 60); also with K₂SO₄

(von Gerichten, B. 6, 162).

THIOSELENATES M12SeSO3. (Selenothiosulphates. Selenosulphates.) Solutions of the normal alkali sulphites dissolve Se, forming these salts. The acid has not been isolated. The salts correspond with the thiosulphates, S

being replaced by Se.

Potassium thioselenate K2SeSO3 aq. Formed by mixing K₂SeAq with SO₂Aq (Cloez, Bl. 3, 112; [2] 4, 419). Better prepared by digesting K2SO3Aq with excess of Se, filtering the cold liquid from Se, and concentrating without heat; crystals of K2SO4 mixed with K2SeS2O6 (v. infra) separate, and K2SeSO3 crystallises from the mother-liquor (Cloëz, l.c.; Rathke, J. pr. 95, 1). White, lustrous, six-sided tablets; deliquescent in moist air; effloresce over H₂SO₄. Decomposed rather easily by heat, giving K polyselenides; cold water separates Se, and forms K₂SeS₂O_g (v. infra); acids evolve SO₂ and separate Se; BaCl₂Aq ppts. BaSO₃ and Se from an aqueous solution of the salt; an ammoniacal solution of Ag,O forms Ag,Se and K,SO,Aq on heating

DITHIO - TRISELENATES MI SeS.O. (Selenotrithionates.) These salts may be regarded as derived from trithionates (M1,S3O,) by replacing S by Se; as the salts M2S2O, are called trithionates, so the salts M'2Se2O, might be called triselenates if they were isolated, and the salts MI_SSeO, may be called dithio-triselenates.

Potassium dithio-triselenate K_SeS_O_s. This salt is formed in the preparation of potassium thioselenate (v. supra); if KHSO_s is present in the K_2SO_s used considerable quantities of K_2SO_SO_s are produced (Rathke, J. pr. 95, 1). It is also obtained by mixing K_2SeSO_s with excess of K_2SO_s and conc. H_2SeO_3Aq. Forms lustrous, greenish-yellow, monoclinic prisms, isomorphous with K_2S_2O_s; stable in air; sol. water without change (Rathke, J. pr. [2] 1, 33). Acids evolve SO_2 and ppt. Se, on warming; ammoniacal solution of Ag_2O ppts. Ag_Se, forming also K_SO_4Aq and H_2SO_4Aq.

Dithio-triselenic acid, H.SeS₂O₆, is said to be present in the solution obtained by the action of excess of SO₂ on SeO₂Aq (Schulze, *J. pr.* [2] 32, 390). M. M. P. M.

SELENHYDRIC ACID H₂Se; v. Hydrogen SELENDE, vol. ii. p. 724.

SELENIC ACID H,SeO₄. Mol. w. not determined. S.G. 2.9508 at 15°; S.G. of superfused acid, 2.6083 at 15° (Cameron a. Macallan, Pr. 46, 18). Melts at 58°; the molten acid may be cooled below 5° without solidifying (C. a. M., l.c.). H.F. [SeO,3,Aq]=76,660; [ScO²Aq,O]=20,500 (Th. 2, 279).

Formation.—1. By passing Cl into H₂SeO₂Aq, and evaporating.—2. By fusing Se or SeO₂ with KNO₂, ppg. BaSeO₄ from solution of the fused mass, decomposing by K₂CO₃, filtering from BaCO₂, neutralising any K₂CO₃ present by HNO₃Aq, ppg. PbSeO₄, and decomposing this salt by H₂S (von Gerichten, A. 168, 214).—3. By heating Se with HNO₃Aq, boiling with HClAq (to reduce any H₂SeO₄ to H₂SeO₃), ppg. traces of H₂SO₄ by adding a little Ba(NO₃),Aq, filtering from BaSO₄, neutralising by Na₂CO₃, evaporating to dryness, heating to dull redness, boiling with HNO₃Aq, ppg. PbSeO₄ by addition of Pb(NO₃),Aq, and decomposing by H₂S (Fabian, A. Suppl. 1, 241).—4. By fusing SeO₂ with excess of KNO₃, boiling with HNO₃Aq, ppg. CaSeO₄ by addition of Ca(NO₃),Aq, decomposing the CaSeO₄ by addition of Ca(NO₃),Aq, decomposing the CaSeO₄ by addition of Ca(NO₃), Aq, decomposing the CaSeO₄ by addition of pure SeO₂ in water, digesting the ppd. Ag₂SeO₃ with water and a slight excess of Br, filtering from AgBr, and evaporating the filtrate, which contains H₂SeO₄ (Thomeen, B. 2, 598).—6. By oxidising H₂SeO₃Aq by K₂CrO₂Aq, PbO₂, or MnO₂ (Wohlwill, A. 114, 169, 176).

Preparation. - SeO2 is heated till sublimation begins; it is then dissolved in water, and BaOAq is added so long as a few drops, when filtered, continue to give a pp. with BaOAq; the filtered liquid is now free from H2SO, and H2SeO,, it is evaporated to dryness, and the residual SeO, is heated till it sublimes (Thomsen, B. 2, 598). The pure SeO₂ thus obtained is dissolved in water, excess of AgNO, Aq is added, the ppd. Ag₂SeO₃ is washed with water and shaken with water and Br-at first Br is added, and then BrAq till the liquid shows a faint orange colour; the liquid filtered from AgBr contains only H2SeO, it is evaporated and treated as described hereafter (T., l.c.). Another method consists in neutralising the solution of pure SeO, by K2CO, evaporating to dryness, fusing with a

little KNO₃ for some time, dissolving in water, slightly acidifying with HNO₃Aq, boiling for some time to decompose any nitrite present, allowing to cool, adding Pb(NO₃)₂Aq, washing the ppd. PbSeO₄, suspending this salt in water, and decomposing it by a rapid stream of H₂S; the filtered liquid is then evaporated (von Gerichten, A. 168, 214).

The solution of H. SeO, is concentrated by evaporation in an open dish on a water-bath so long as water passes off; an acid containing c. 83-84 p.c. H2SeO4 is thus obtained; this acid is placed in a small flask connected with a short wide tube containing solid KOII, which is connected with a large U tube also containing solid KOH; the U tube is connected with the receiver of an airpump, or with a vessel in connection with a good water-pump. The air is pumped out of the apparatus, and when a good vacuum is obtained the small flask is heated to 100° so long as acid distils over (this is known by the KOH effervescing slightly, as ordinary KOH contains K2CO3); the temperature is then raised to 180° (an oilbath being used to heat the flask), and heating at this temperature is continued so long as acid distils off; as soon as the potash ceases to be acted on the heating is stopped and the flask is at once cooled; a very good vacuum must be maintained throughout the process. H, SeO. crystallises as the flask is cooled. A small quantity of H2SeO4Aq should be evaporated thus at a time (Cameron a. Macallan, Pr. 46, 13).

Properties.—A white crystalline solid, crystallising in long hexagonal prisms, and melting at 58° to a colourless oily liquid. The liquid acid may be cooled below 5° without solidifying if it is not stirred; a crystal of H₂SeO₄ dropped into the liquid causes it to solidify at once, the temperature rising to 58°. The liquid acid is specifically lighter than the solid (v. data at beginning of article) (C. a. M., Le.). H₂SeO₄ is very hygroscopic; it mixes with water, with production of heat.

The following table is taken from Cameron and Macallan (l.c.):—

mu mucu	12022 (0.00)		
P.c. H ₂ SeO ₄	S.G. H.SeO.Aq at 15°	P.c. H ₂ SeO ₄	S.G. H ₂ SeO ₄ Aq at 15°

Reactions.—1. With water much heat is produced, and hydrates are probably formed (v. infra, Hydrates of selenic acid). H.SeO. acts as a dehydrating agent, similarly to H.SO. (C. a. M., l.c.).—2. Heated in vacuo begins to decompose into O, H.O. and SeO. at c. 200°; the water formed dilutes the remaining acid, which then distils over. When dilute H.SeO.Aq is heated at ordinary pressure water distils off till temperature rises to 205°, when the acid has the

composition H₂SeO₄.H₂O; traces of H₂SeO₄ then distil over: at 260° white fumes of H,SeO, come off. When H2SeO, is strongly heated at the ordinary pressure, some of it is decomposed to SeO₂, O, and H₂O; the remaining acid is diluted by the water till a dilute acid distils off (C. a. M., l.c.).—3. Dilute H₂SeO₄Aq dissolves many metals, with evolution of H; warm conc. acid dissolves copper and gold, with partial reduction to H.SeO3.-4. Digestion with hydrochloric acid reduces H, SeO, Aq to H, SeO, Aq, with evolution of Cl; the acid is not reduced by sulphur dioxide nor by sulphuretted hydrogen .-5. Sulphur reacts with liquid H.SeO, at c. 60°, forming a deep-blue, very unstable substance (? SeSO₂) which decomposes to SO₂ and H₂SeO₃ (C. a. M., l.c.). -6. Selenion dissolves in H2SeO4, giving a green unstable substance—? Se₂O₃ (C. a. M., l.c.).—7. Tellurium dissolves in H₂SeO₄, forming a reddish body, probably TeSeO₃ (C. a. M.).—8. Heated with phosphoric anhydride, SeO2 is given off; but at a lower temperature crystals were obtained which C. a. M. think were SeO₃.

Hydrates of selenic acid. The monohydrate H₂SeO₄H₄O was obtained by C. a. M. (Lc.) by diluting H₂SeO₄ to 88.96 p.c., freezing at -23°, melting and re-crystallising by freezing several times. This hydrate forms long needles, melting at 25°, and remaining liquid even 50° below its melting-point; Pickering (priv. comm.) gives melting-point as 16·6°. S.G. of solid hydrate = 2·3257 at 15°; S.G. of superfused hydrate = 2·3557 at 15°. C. a. M. did not succeed in obtaining other hydrates as solids. For salts of H₂SeO₄ v. Selenates, p. 433.

M. M. P. M. **SELENIDES.** Se combines with most metals when heated with them. Se also combines with many non-metals, e.g. with B, Br, Cl, F, H, I, O, P, and S. Many metallic selenides are formed by heating the elements together (Uelsmann, A. 116, 122; Schneider, A. 97, 192; Little, A. 112, 211); also by the interaction of Se and metallic salts (Schneider, P. 127, 642; Potilitzin, B. 12, 697); sometimes by the interaction of Se and metallic sulphides at high temperatures (P., l.c.). For thermal data regarding the formation of many metallic selenides v. Fabre (C. R. 102, 1469; 103, 269, 345). Selenides of the alkali metals are sol. water; they are formed by saturating the hydroxides in water by H₂Se (Fabre, C. R. 102, 613), by reducing the selenites by C (Wöhler a. Dean, A. 97, 1), by reducing selenates by H at 200° (Fabre. C. R. 102, 1469), and by heating the elements together (Uelsmann, A. 116, 122). The selenides of metals other than the alkali metals are insol. M. M. P. M.

SELENION. Se. (Selenium.) At. w. 78·8. Mol. w. 157·6 (v. infra). M.P. 217° for crystalline variety (Hittorf, P. 84, 214; Draper a. Moss, C. R. 83, 1; v. Action of heat on selenion). Boils at 676°-683° (Carnelley a. Williams, C. J. 35, 563). S.G. c. 4·7 crystalline; c. 4·3 amorphous (for more details v. description of varieties of Se, infra). V.D. 111 at 860°, 92 at 1040°, 82 at 1420° (Deville a. Troost, C. R. 49, 239; 56, 891). S.H. crystalline - 20° to +7° = 0732, crystalline 20° to 98° = 0762, amorphous - 27° to +8° = 0746, amorphous 19° to 87° = 1036 (Regnault,

A. Oh. [3] 46, 257). C.E. vitreous at 40° = 0000368 (Fizeau, C. R. 68, 1125; cf. Spring, B. 14, 2580). For E.C. v. infra. $\mu_{\lambda} = 2.654$, $\mu_{\alpha} = 2.692$, $\mu_{\beta} = 2.98$ (v. Sirks, P. 143, 429). For emission and absorption spectra v. B. A. 1884. 440. H.C. [Se, 0] = 57,080; [Se, 0^3, Aq] = 76,660 (Th. 2, 274).

Historical.—In 1817 Berzelius (S. 23, 809) obtained a new element from the crystals formed in the leaden chamber of a sulphuric acid works at Gripsholm in Sweden; as the new element was found to resemble tellurium (discovered in 1798 by Klapstock), Berzelius gave it the name selenion (σελήνη = the moon). As Se is distinctly a non-metallic element, and as the termination um is characteristic of the names of metals, it seems altogether improper to use the name selenium rather than selenion.

Occurrence.—In small quantities uncombined with other elements; in combination with various metals, such as Bi, Cu, Pb, Hg, Ag, generally along with sulphur. Most selenion-containing metallic sulphides are very poor in Se; but certain selenides from the Argentine Republic contain from 29 to 48.5 p.c. Se, combined with Cu, Pb, and Ag. Minerals containing Se are fairly widely distributed, but occur only in small quantities (Stromeyer, S. 43, 452; MacIvor, C. N. 56, 251; Nordström, B. 12, 1723; Pisani, C. R. 88, 391; Hensler a. Klinger, B. 18, 2556; Stelzner, J. 1874. 1234). When sulphides which contain Se are roasted, the Se condenses in the flues. The deposits that form in sulphuric acid chambers often contain Se; and many specimens of the acid also contain this element. Commercial HClAq sometimes contains Se, derived from the H₂SO₄ used in making the HClAq Kemper, J. 1860. 84; Nilson, B. 7, 1719; Lamy, C. R. 74, 1285; Scheurer-Kestner, C. R. 74, 1286; Personne, C. R. 74, 1199; Drinkwater, An. 8, 63).

Formation.—1. By passing SQ, into H₂SeO₃Aq; H₂SeO₃Aq + 2SO₂ + H₂O

=2H₂SO₁+Se.—2. By allowing the solution of an alkali selenide to stand in air (Böttger, J. pp. 71, 512).—3. By adding acid to solution of a thio-selenate (Böttger, J. pp. 94, 439), or to KCNScAq (Oppenheim, J. pp. 71, 266).—4. By the action of such metals as Zn or Fe on H₂ScO₂Aq made strongly acid by HCl or H₂SO₂.
5. By heating (NH₄)₂ScO₃ or (NH₄)₂SeO₄.

Preparation .- 1. From the flue-dust formed in roasting sulphides containing Se. The flue-dust is washed with water, dried, and distilled; this method is applicable to dusts rich in Se. Dusts poorer in Se are washed, the heavier particles are lixiviated with dilute HClAq and then with water, dried, fused with pearlash and soda, and washed with water; the solution of alkali selenide thus obtained is allowed to stand in the air, and the Se which ppts. is washed, dried, and distilled (Böttger, J. pr. 71, 512). Or the washed dust is made into a thin paste with equal volumes of H2SO, and H2O, heated to boiling, with addition from time to time of a little HNO, or KClO, till the red colour of the liquid is destroyed, conc. HClAq is added equal to half the volume of the liquid, and the whole is evaporated to one-fourth its bulk, whereby Cl is evolved and H2SeO, is reduced to H2SeO,; SO, is passed into this solution, the ppd. Se is washed, dried, and distilled (Wöhler, G. A. 69, 264).—2. From the deposit in the leaden chambers of sulphuric acid works. The washed deposit is boiled with conc. Na, SO, Aq till it is black (from formation of PhS), and the liquid, which contains Na, SeO₂, is filtered into dil. HClAq, whereby Se is ppd. This process is repeated several times (Böttger, J. pr. 94, 439). Or the washed deposit is digested at 80°-100° with fairly conc. KCNAq until the red colour of the liquid has changed to grey, the liquid is filtered, the residue washed with boiling water till HClAq ceases to produce a reddish opalescence in the washings, and excess of HClAq is added to the filtrate and washings, whereby Se is ppd. (KCNAq+Se=KCNSeAq; KONSeAq+HClAq=KClAq+HCNAq+Se). The ppd. Se is dissolved in HNO, Aq, the solution is evaporated (slowly, to prevent loss of SeO₂) to dryness, the SeO₂ is sublimed in a tube of hard glass in a stream of dry dust-free air, the sublimate is dissolved in water, HClAq is added, and Se is ppd. by SO₂ (Oppenheim, J. pr. 71, 266). Se, as prepared by reducing cold H.SeO, Aq, is

a red amorphous powder; an amorphous vitreous variety is obtained by melting ppd. Se and cooling very rapidly by pouring on to a porcelain plate (Hittorf, P. 84, 214; Rammelsberg, P. 152, 151; Regnault, A. Ch. [3] 46, 257); a black crystalline variety of Se is prepared by allowing conc. K2SeAq or Na2SeAq to stand in air until a crust forms on the surface (H., l.c.; R., l.c.), also by crystallising any form of Se from Se₂Cl₂ (Rathke, A. 152, 181); a red crystalline variety is prepared by slowly and repeatedly heating a solution of Se in CS₂ in a sealed tube to somewhat under 100°, and allowing to cool (R., l.c.; Rathke, A. 152, 181), also by subliming amorphous Se (Bornträger, D. P. J. 242, 55); a grey metal-like variety is prepared by very slowly heating amorphous or red crystalline Se to 96°-97° (H., l.c., R., l.c.; Fabre, C. R. 103, 53). According to Schutze (J. pr. [2] 32, 390) a col-loidal soluble form of Se is obtained by reducing H₂SeO₃Aq by SO₂; no acid must be present. The colloidal Se remains in solution, colouring the liquid dark red. The solution is not changed by boiling but on adding an acid or a salt Se is ppd. in red flocks.

Properties.—Se exists in several, probably in five, forms.

I. Amorphous selenion; sol. in CS_x —

(i.) Red-powdery amorphous Seforms sealing-waxred flocks, or when dried at a low temperature a
dark-red powder; when formed by reduction of hot H_x SeO_xAq it appears as a black powder (Hittorf, P. S4, 214). S.G. at 20°=4°3 (Rammelsberg, P.152, 151; Schaffgotsch, P. 90, 66); 4°2 (Rathke, A. 152, 131). This variety is a non-conductor
of electricity (Hittorf, l.c.). It is sol. CS₂; S.
at b.p. of CS₂(46·6°)=1, at 0°=016 (Mitscherlich, J. 1855. 314); according to Rammelsberg
(l.c.) the solubility in CS₂ varies much. For
S.H. v. beginning of this article. Petersen
(Z. P. C. 8, 601) gives H.C. of this variety
[Se,0°]=57,250, and at. vol. 18·4; the change
from this form to any other form of Se is
attended with contraction and the production
of a small quantity of heat. For action of heat p. infra.

(ii.) Amorphous vitreous Se forms a black lustrous solid, appearing red in thin layers. S.G. 4-282 at 20° (Schaffgotsch, J. pr. 43, 308; 60, 312). Sol. in CS. No fixed melting-point; when heated it softens at 60°, and becomes gradually less viscous till at 250° it is quite liquid; if this liquid is rapidly cooled, the vitreous variety is re-formed (Hittorf, Lc.; Draper a. Moss, C. N. 33, 1). Heated very slowly to 96°-97° this variety changes to metallic Se, with production of heat (R., Lc.; Regnault, A. Ch. [3] 46, 257; Fabre, C. R. 103, 53).

A. Ch. [5] 40, 251; RADE, C. R. 105, 55).

II. Crystalline selenton; insol. in

CS₂—(i.) Black crystalline Se. Small, microscopic, glittering leaflets. S.G. 48 (R., L.);

476 to 478 at 15° (Mitscherlich, J. 1855. 314).

Insol. CS₂. H.C. [Se,O'] = 55,820; at. vol. = 16·5; change from amorphous Se to this form is accompanied by slight production of heat and
contraction (Petersen, Z. P. C. 8, 601).

(ii.) Red crystalline Se. Small, thin, transparent, lustrous crystals; in thicker layers appears black and opaque. S.G. 4·46 to 4·5 at 15° (R., l.c.; M., l.c.; Rathke, l.c.). Melts at 217° (H., l.c.; D. a. M., l.c.). Insol. incCs. Petersen (l.c.) gives H.C. [Se,O'] = 56,200; and at. vol. = 17·7. This variety is a conductor of electricity, the conductivity increasing with increase of temp. and also by exposure to light. (For details, v. infra.) When heated to c. 110° this variety becomes black. The crystals are monoclinic, ratio of axes = 1·62:1:1·6 (M., l.c.; Reguault, l.c.); isomorphous with monoclinic S (R., l.c.). For S.H. v. beginning of this article.

(iii.) Grey metallic Se. Lustrous, grey, metal-like, granular solid, resembling grey pigiron; somewhat malleable (Regnault, Lc.). Insol. in CS. S.G. 4.4 to 4.5 (R., Lc.). Melts at 217° (H., Lc.); on cooling, the vitreouts variety is chiefly formed, but if the cooling is stopped at 210° after a time there is a sudden rise to 217°, and the whole solidifies in the metallic form. All varieties of Se are sol. Se₂Cl₂ and SeEt..

Action of heat on selenion. Any one of the crystalline varieties of Se melts at 217°; when the molten Se is allowed to cool slowly it gradually becomes less soft, a thermometer placed in the cooling substance continuously falls and shows no point of rest (Hittorf, l.c.; Regnault, l.c.); the final product is crystalline Se, but if the cooling is caused to take place rapidly the amorphous vitreous variety is formed; if the cooling is stopped at 210°, and that temperature is maintained for some time. there is a sudden rise to 217° and the Se again solidifies in the crystalline (metallic) form.
When amorphous Se is heated it softens at c. 60°, and becomes gradually less viscous until at 250° it is quite liquid; if the heating is very gradual, there is a sudden evolution of heat at 96-97° (Riegnault, L.c., found temperature rise to 200°-230°), and the metallic variety is produced. Se boils at 676°-683°, forming a reddish. yellow vapour, the V.D. or which does not become constant until 600°-700° above the b.p.

Effects of light and heat on the electrical conductivity of crystalline selenion. Amorphous Se does not conduct electricity; but when heated rapidly it begins to conduct at 165°-175°, and conductivity increases until it attains a

SELENION. 488

maximum at c. 217° (Draper a. Moss, C. N. 33, 1). Crystalline Se conducts, the conductivity increasing proportionally with increase of temperature to 217°, after which it decreases and reaches a minimum at 250° (Hittorf, P. 84, 214; D. a. M., l.c.). If Se is heated for a considerable time to 200° and is then allowed to cool, conductivity decreases as temperature rises and increases as temperature falls (W. Siemens, P. 159, 117). This observation seems to show that at c. 200° a variety of Se is formed which behaves like a metal, and that on cooling this form remains mixed with the ordinary crystal-line variety, so that the conductivity depends on the relative quantities of the two forms, and therefore on the temperature (cf. Kalischer, W. 31, 101). The electrical conductivity of crystalline Se increases enormously when the Se is exposed to light (Sale, Pr. 21, 283; Smith, B. 6, 204; Rosse, P. M. [4] 47, 161; Forssmann, W. 2, 513). Adams and Day (Pr. 24, 163) found that the resistance of Se varied directly as the square root of the intensity of the source of light; also that light caused an electric current in Se from the less to the more illuminated part (Pr. 25, 113; cf. Bidwell, C. N. 52, 191).

Se may be sublimed and distilled in vacuo, or in an indifferent gas (Schuller, J. 1884. 1550); heated in air it is burnt to SeO₂. Se dissolves in conc. H2SO, forming SeSO, and is ppd. again on adding water; Se is sol. in alkali solutions, forming alkali selenides; also in KCNAq, in alkaline sulphite solutions, in Se, Cl, Se, Br., and SeEt4; the amorphous varieties are

al. sol. CS₂

Se resembles S and Te in its chemical character; it is somewhat less negative than S and more negative than Te; it shows distinct analogies with Cr, Mo, W, and U (v. Oxygen GROUP OF ELEMENTS, vol. iii. p. 705; and CHRO-MIUM GROUP OF ELEMENTS, vol. ii. p. 168).

The atomic wt. of Se has been determined (1) by analysing SeCl, (Berzelius, P. 8, 21 [1818]); (1) by analysing SeU₁ (herrenus, P. 8, 21 [1613]);
(2) by analysing K₂SeO₁ (Mitscherlich a. Nitzsch, P. 9, 627 [1827]; (3) by oxidising Se to SeO₂, by reducing SeO₂ to Se, and by analysing BaSeO₃ (Sace, A. Ch. [3] 21, 119 [1847]); (4) by analysis of HgSe (Erdmann a. Marchand, J. pr. 55, 202 [1849]); (5) by converting Sc into SeCl, (Dumas, A. Ch. [3] 55, 186 [1859]; (6) by reducing SeO₂ to Se and by analysing Ag,SeO₃ (Pettersson a. Ekman, B. 9, 1210 [1876]; (7) by determining S.H. of Se (Regnault, A. Ch. [3] 46, 257); (8) by determining V.D. of, and analysing, SeH₂, SeO₂, Se₂Cl₂, SeCl₄, and SeBrCl₄.

The molecular wt. of Se has been found by determining the V.D. of Se at 860°, c. 1000°, and c. 1400°; the values at 1400° agree with the

formula Se₂.

The atom of Se is divalent in the gaseous molecule SeH₂, and tetravalent in the gaseous molecules SeCl₁ and SeBrCl₃.

Reactions and Combinations .- 1. Water and ozone produce H.SeO. (Mailfert, C. R. 94, 860, 1186). Water alone does not react at 160° (Cross a. Higgin, C. J. 35, 249).—2. Conc. sulphuric acid dissolves Se on warming, forming H₂SeO₂, and some H₂SeO₄, and giving off SO₂. Fuming sulphuric acid forms a greenish solution containing SeSO, (v. Thio-oxide, p. 441); on boiling H2SeO2 is formed and SO2 evolved

(Divers a. Shimosé, B. 18, 1209).-3. Hot coric. nitric acid oxidises Se to H.SeO, with evolution of NO. Hydrochloric acid does not react with Se.-4. Se dissolves in alkali solutions, forming alkali selenides; fusion with alkalis produces the same compounds .- 5. Fusion with nitre or potassium chlorate forms K.SeO. - 6. Potassium cyanide solution dissolves Se to KCNSeAq. 7. Solutions of alkali or alkaline earth sulphites dissolve Se, forming thioselenates (Rathke a. Zschiesche, J. pr. 92, 141; Uelsmann, A. 116, 123; v. also Thioselenares, p. 434).—8. Se vapour passed over heated lead fluoride forms Se fluoride (Knox, Pr. Irish Acad. 1841. 299).— 9. Se combines with oxygen to form SeO2, when heated in O or air .- 10. Se combines with chlorine, bromine, and iodine at the ordinary temperature.-11. Heated to low redness with hydrogen, H2Se is formed (Uelsmann, A. 116, 122).-12. Phosphorus combines at the ordinary temperature.-13. Se combines with arsenic and antimony, by heating the elements together .-14. Selenides of most metals are formed by heating Se with metals (v. Selenides, p. 436). Sometimes the combination is effected without heat, under the influence of light (v. Bidwell, P. M. [5] 20, 178; Moss, C. N. 33, 203).—15. Se dissolves in molten sulphur, but no definite compounds are formed in this way.-16. With sulphuric anhydride Se combines to form SeSO₃ (v. Thio-oxide, p. 441).

Selenion, acids of. Sclenhydric acid H.Se, vol. ii. p. 724; selenic acid H₂SeO₃, p. 435; selenicus acid H₂SeO₃, p. 445; Selenocyanhydric acid HCNSe, vol. ii. p. 348; also Selenocyanic acid, this vol. p. 443; salts of thioselenic acids, H2SeSO3 and H2SeS2O6, are known, p. 434; and salts of sclenosamic acids, Se(NH2)OM1 and 2SeO(NH.).OH.OMI, have been isolated, p. 446.

Selenion, antimonide of; v. vol. i. p. 283,

Antimony, Combinations of, No. 6.

Selenion, arsenides and arsenosulphides of; v. vol. i. p. 303, Arsento, Combinations of, No. 7.
Selenion, boride of. A yellow-grey solid is formed by strongly heating amorphous B in a stream of H.Se; the solid is decomposed by water with rapid evolution of H.Se (Sabatier, C. R. 112, 865). As S. gives the formula B₂S₃ to the boron sulphide formed by passing H.S. over B, it is probable that the Se compound has the composition B.Se.

Selenion, bromides of. Two compounds of Se and Br are known, Se, Br, and SeBr,; both are formed by the direct union of the elements. Both are decomposed by heat, but they are more stable towards heat than the corresponding S compounds (Evans a. Ramsay, $C. \hat{J}$. 45, 62). As the V.D. of neither has been determined, the formulæ are not necessarily molecular; but from the analogy of Se₂Cl₂ and SeCl₄, which formulæ represent the compositions of gaseous molecules of these chlorides, it is probable that the mol. wts. of the bromides correspond with the formulæ Se₂Br₂ and SeBr₄.

SELENIOUS BROMIDE Se₂Br₂. (Selenion monobromide.) Formula probably molecular, from analogy of Se,Cl. To 15.9 parts powdered Se covered with three times its weight of dry CS2, 16 parts Br are gradually added; after a time the CS, is distilled off; and Se, Br, remains as a thin oily liquid, having a dark reddish-brown colour (appearing black in a thickish layer), and an unpleasant smell resembling that of S₂Cl₂ (Serullas, A. Ch. [2] 35, 349; Schneider, P. 128, 327). A thin layer of Se₂Br₂ transmits rose-red light; the absorption spectrum has been examined by Gernez (C. R. 74, 1190). S.G. of Se₂Br₂ = 3·604 at 15°. Bris given off on heating, then a little SeBr₄, and at 225°-230° most of the Se₂Br₂ distils over, and finally some Se is obtained (Schneider, l.c.). Se₂Br₂ dissolves in all proportions in CS₃, less easily in CHCl₃, EtBr, and EtI. It sinks in water, and then decomposes to H₂Se₂Aq, HBrAq, and Se. Absolute alcohol forms SeBr₄ (which remains dissolved) and Se. Se₂Br₂ dissolves Se (c. 22 p.c.), on adding CS₂ the Se separates. Br is absorbed by Se₂Br₂, in CS₂ shaken with dry AgCN forms a little Se cyanide (Schneider, P. 129, 634).

Selenio Bromide SeBr. (Selenion tetra-bromide.) Formula probably molecular, from analogy of SeCl. To a solution of 1 part SeBr. in CS₂ 1½ parts Br are gradually added, the SeBr, which separates is allowed to stand in contact with the CS2 for some days, whereby it becomes crystalline, and the CS, is distilled off; the compound obstinately retains some CS₂. By heating to 75°-80° Br is given off, and the SeBr,, containing Se₂Br₂, sublimes in black, lustrous, six-sided leaflets, mixed with a little pure SeBr, in dark-orange crystals, and Se₂Br₂ remains (Schneider, P. 129, 450). SeBr, is also obtained by dissolving 1 part powdered Se in 10-12 parts Br, pressing the crystalline mass between filter-paper, and removing excess of Br by gently warming. SeBr, dissolves in CS2, CHCi, and EtBr; it dissolves with decomposition in alcohol, also in HClAq. SeBr, is very hygroscopic; in moist air it gives Br and Se,Br₂; in much water it forms H₂SeO₄Aq and HBrAq. Combines with SO₃ to form SeCl₄SO₃ (v. Selenion thio-oxychloride, p. 441). Forms compounds with KBr and NH₄Br, K₂SeBr₆ and $(NH_i)_2SeBr_6$ (v. Muthmann a. Schäfer, B. 26, 1008).

Selenion, bromochlorides of. Two compounds of Se, Br, and Cl were obtained by Evans and Ramsay (C. J. 45, 68) by the interactions of Se₂Cl₂ and Br, and Se₂Br₂ and Cl. The bromochlorides thus formed are SeBrCl₃ and SeBr₂Cl.

Selenion tribromochloride SeBr₃Cl.
Orange, hygroscopic crystals formed by adding 2·1 parts Br, in CS₂, to 1 part Se₂Cl₂, crystalsing from CS₂, and gently warming in a current of air to remove adhering CS₂ (Se₂Cl₂ + 3Br₂ = 2SeBr₃Cl). Decomposes when heated, giving off Br; as V.D. at 200° was c. half that calculated for SeBr₃Cl, dissociation is probably complete at that temperature.

Selenion Bromotrichloride SeBrCl₃. Mol. w. 264-66. V.D. at 179° and 754 mm. pressure = 131-5; dissociation begins at c. 190°-200°. Yellow-brown crystals; obtained by passing Cl into Se,Br₂ in CS₂, washing the pp. with CS₂, and drying in a current of warm air. Gives off Br when heated above c. 190°, and yields sublimate of SeBr₄.

Selenion, carbide of, v. Carbon selenide, vol. i. p. 693.

Selenion, chlorides of. Two chlorides are formed by passing Cl over heated Se; using an excess of Se the product is Se₂Cl₂, and with an excess of Cl the product is SeCl₄. Attempts to form SeCl₂, corresponding with SCl₂, have been unsuccessful.

SELENIOUS CHLORIDE Se₂Cl₂. (Selenion monochloride. Selenion selenochloride.) Mol. w. 228'34. V.D. 110 at 200°-250° (Evans a. Ramsay, C. J. 45, 62; Chabrié, Bl. [3] 2, 803). S.G. 2'906 at 17'5° (Divers a. Shimosé, C. J. 45, 198). Boiling begins at c. 145°, but no definite b.p. can be given (K. a. R., l.c.). H.F. [Se²,Cl²] = 22,150 (Th. 2, 405).

Formation.—1. By passing Cl over excess of heated Se.—2. By heating SeCl₄ with Se at 100° (Borzelius, P. 9, 225).—3. By passing HCl into a solution of Se in fuming H₂SO₄ (Divers a. Shimosé. C. J. 45, 194, 198).

Preparation.—HCl gas is passed into a solution of Se in furning H₂SO₄ till a deep-red liquid is deposited and the mother-liquor is yellowish-brown; the mother-liquor is then poured off, the red liquid is dissolved in fresh furning H₂SO₄ and HCl is passed in; this process is repeated again; finally, the red liquid is digested, in a closed vessel, with dry KCl (to remove H₂SO₄) and decanted (D. a. S., l.c.). The reactions are probably (1) 2SeSO₃+2HCl = SeSO₂·SeCl₂+H₂SO₄; (2) SeSO₃·SeCl₂+HCl = Se₂Cl₂+SO₂·Cl.OH (D.

a. S.).

Properties, Reactions, and Combinations.—
Se,Cl₂ is a heavy, deep-red liquid, smelling something like S.Cl₂; S.G. 2-906 at 17·5°; somewhat volatile at ordinary temperatures, giving off orange-coloured vapour at 100°, beginning to boil at c. 145°, but exhibiting no fixed b.p. (E. a. R., l.c.). V.D. determined at c. 200° gave results agreeing with Se,Cl₂ For absorption spectrum of vapour v. Gernez, C. R. 74, 1190. Se,Cl₂ is easily sol. CS₂, CHCl₃, C,H₆, and CCl₄. It is slowly decomposed by H.O. EtOH, and Et₄O; a solution in CS₂ shaken with water gives H₂SeO₂Aq, HClAq, and Se. Warm Se₂Cl₂ dissolves Se freely; on cooling the Se is partly ppd. in the metal-like form (Bathke, A. 152, 181). Se₂Cl₂ is decomposed by shaking with Hg or Ag (D. a. S., l.c.); with P it gives PCl₂ and Se (Baudrimont, A. Ch. [4] 2, 5). Se₂Cl₂ combines with PCl₃ to form a yellow substance (B., l.c.).

SELENIC CHLORIDE SeCl. (Selenion tetrachloride.) Mol. w. 220-28. V.D. at 180°=110 (Evans a. Ramsay, C. J. 45, 65). H.F. [Se,Cl'] = 46,160 (Th. 2, 405).

Formation.—1. By heating Se, or Se,Cl., in excess of Cl.—2. By heating SeO₂ with PCl₃ (v. Preparation).—3. By the action of SOCl₂ on SeOCl...

Preparation. To 13 parts PCl₃ in a long-necked flask 7 parts SeO₂ are added tittle by little, the reaction being allowed to cease after each addition before more SeO₂ is added (SeO₂+PCl₃=SeOCl₂+POCl₃); the mass becomes liquid and then suddenly solidifies (3SeOCl₂+2POCl₃=3SeCl₄+P₂O₃); excess of POCl₃ is now removed by heating the flask while a rapid stream of dry CO₂ is passed through it; a wide tube is then fitted by a cork into the neck of the flask, and the flask is placed in a tray containing hot sand (if the flask is

allowed to cool the condensing P2O2 may cause

it to crack) (Michaelis, J. Z. 6, 79).

Properties, Reactions, and Combinations.

A slightly yellow crystalline solid; volatilises when heated, without melting, in yellow vapours. Evans a. Ramsay (C. J. 45, 65) found V.D. at 180° to be 110, agreeing with the formula SeCl₄; dissociation to Se₂Cl₂ and Cl began at c. 210°, and at 350° c. 66 p.c. was decomposed. Clausnizer (B. 11, 2007) got the value 57 for V.D. at 218°, at which temperature E. a. R.'s value was c. 86; at 368° Chabrić (Bl. [3] 2, 803) obtained the number 57, which agrees fairly with phide; SO, has no action. NH₃Aq produces Se, N, and H at ordinary temperatures, and N selenide at a low temperature (Verneuil, Bl. [2] 38, 548). Dry NH, combines with SeCl, at -20°, forming a very unstable compound, probably SeCl, 4NH, (V., Lc.). With PCl, the compound SeCl, 2PCl, is formed (Baudrimont, A. Ch. [4] 2, 5).

Selenion, chlorobromides of, v. Selenion

BROMOCHLORIDES, p. 439.

Selenion, cyanide of; v. Cyanogen selenide,

vol. ii. p. 358.

Selenion, fluoride of. No definite compound of Se and F has been isolated. According to Knox (Pr. Irish Acad. 1841. 299) a fluoride of Se sublimes when Se vapour is passed over

molten PbF₂.

Selenion, haloid compounds of. Se comcompounds, Se, X, and SeX, (the fluorides have not been examined); the formulæ are probably molecular, as the V.D.s of Se,Cl, and SeCl, have been determined. The compounds Se₂X₂, where X = Cl or Br, are liquids at ordinary temperatures; the other compounds are solids. All the compounds are fairly easily decomposed by heat, but less easily than the corresponding S haloid compounds.

Selenion, hydride of; v. Hydrogen selenide,

vol. ii. p. 724.

Selenion, hydroxides of. The hydroxides of Se, SeO(OH)₂, and SeO₂(OH)₂ are acids; v. Selenious acid, p. 445, and Selenic acid, p. 435.

Selenion, iodides of. Two compounds of Se and I are known, Se2I2 and SeI4, corresponding

with the bromides and chlorides.

Selenious Iodide Se₂I₂. (Selenion mono-iodide.) Formula probably molecular, from analogy of Se.Cl. Formed by heating the elements together in the ratio Sc:I(1:1.61); also by heating Se, Br, and EtI at 100' in a sealed tube (Schneider, P. 129, 627). Crystalline, steel-grey, somewhat metal-like solid; melting to a dark-brown liquid at 68°-70°. Decomposed to Se and I by continued heating at 100°; also by solvents of I. Water forms H2SeO3Aq, HIAq, and Se.

Selenio iodide Sel. (Selenion tetra-iodide.) Formula probably molecular, from analogy of SeCl. Formed by heating together Se and I in the ratio Se:4I(1:6:44); also by mixing SeBr. and Etl in the ratio SeBr4:4Etl, the SeI4 separates after a little. Best prepared by adding

HIAq to conc. H.SeO.Aq as long as a pp. is produced; the pp. is washed, pressed, and dried over H₂SO₄ (Schneider, *l.c.*). A dark-grey solid, melting at 75°-80° to a blackish-brown liquid. Gives up all I when heated to c. 100°, or treated with solvents of I; slowly decomposed by water. Attempts to form an iodochloride of selenion were unsuccessful (v. Evans a. Ramsay. C. J. 45, 70).

Selenion, nitride of: v. Nitrogen selenide,

vol. iii. p. 570.

Selenion, oxides of. Only one oxide of Se has been isolated with certainty; this oxide is SeO₂. Berzelius thought that an oxide SeO was formed, along with SeO₂, by heating Se in air or O, by heating Se and SeO₂, and by the partial oxidation of Se sulphide by HNO₃. According to Chabrié (A. Ch. [6] 20, 202) Se takes up O approximately corresponding with that required to form SeO, when heated in air to 180°. Attempts to prepare SeO₃ have failed. By passing gaseous SeO₂ and O over hot spongy Pt, von Gerichten (A. 168, 214) obtained a white sublimate that dissolved in water with a hissing sound, forming H2SeO4, but Cameron a. Macallan (Pr. 46, 32) failed to confirm this result; C. a. M. (l.c.) did not get SeO₃ by passing O over hot Pt sponge mixed with Se, nor by the action of ozone on ScO2, nor by heating selenate of Sb, Bi, Fe, Pb, Hg, or Ag. By heating dry H₂SeO₄ with P₂O₅ in a closed flask they got a trace of a crystalline solid, analyses of which pointed to the composition SeO₃. A solution of Se in H₂SeO₄ perhaps contains Se₂O₄ (v. Selenic acid, Reactions, No. 6, p. 436).

SELENION DIOXIDE SeO₂. (Selenious oxide, Selenious anhydride.) Mol. w. not determined. S.G. 3.9538 at 15° (Cameron a. Macallan, Pr. 46, 27; Clausnizer, A. 196, 265). [Se,0²] = 57,250 from amorphous Se; 55,820 from black crystalline Se; 56,200 from red crystalline Se (Petersen, Z. P. C. 8, 601). Melts at 340° in a sealed tube; at ordinary pressure volatilises without melting, slowly at 250°, rapidly at 280° (Chabrié, A. Ch. [6] 20, 202; C. a. M., Le.). For absorption-spectrum of SeO₂ vapour v.

Gernez (C. R. 74, 803).

Preparation.—1. Se is placed in the lower part of a V-tube with one limb longer than the other, and the longer limb drawn to a fine opening; the shorter limb is connected with a gasholder, from which a stream of dry O is passed into the V-tube; the tube is heated till the Se burns; the SeO, condenses in the longer limb of the tube. -2. Se is dissolved in conc. HNO, Aq, the solution is evaporated to dryness, best in a retort (solidification occurs suddenly, with evolution of heat); the dry H2SeO3 is heated in the retort till sublimation begins, then let cool, and dissolved in water; the solution is ppd. by BaOAq; the solution, after filtering, is evaporated to dryness, and the residue is heated, when SeO2 sublimes; traces of H2SeO4 and H2SO4 are thus removed, excess of BaO remains in the residue (Thomsen, B. 2, 598; cf. Wohlwill, A. 114, 176; Fischer, P. 67, 412).

Properties and Reactions.-Long, white, lustrous, four-sided needles (for m.p. &c. v. beginning of this article). 1. Slowly withdraws water from moist air, forming H₂SeO₃; dissolves in water, forming same soid, with disappearance of

heat, $[SeO^2,Aq] = -920$ (Th. 2, 405).—2. Sl. sol. boiling acetic axhydride, crystallising un-changed; heated to 180°-200° oxidation of the Ac.O occurs (to CO₂, &c.) and Se separates (Hinsberg, A. 260, 40).—3. Dissolves in aqueous acetic acid, H₂SeO₃ separating on cooling (H., l.c.).—4. Dissolves in alcohol of 96 p.c., and is re-obtained on evaporation over H.SO. (H., l.c.). 5. Reacts with phosphoric chloride to give SeCl., P₂O₅, and POCl₂; heated with phosphoryl chlor-ide gives SeOCl₂ and P₂O₅ (Michaelis, J. Z. 6, 79).—6. Heated with sodium chloride yields SeOCl2 and Na2SeO3 (Cameron a. Macallan, Pr. 46, 35) .- 7. Heated with selenion tetrachloride in a closed tube produces SeOCl₂; with SeBr, probably forms SeOBr₂ (Schneider, P. 129, 450). 8. Decomposed by dry ammonia to H2O, Se, and N; when NH, is passed into SeO, in absolute alcohol, SeO(NH,).ONH, is formed (v. Selenos-AMIC ACIDS, SALTS OF, p. 446). -9. Heated with dry HCN and Ac.O. Se cyanide is probably formed (Hinsberg, A. 260, 40).—10. Hydriodic acid (Hinsberg, A. 200, 40).—10. Hydrions acta reduces SeO, to Se and H.O, even at 10°.—11. SeO₂ and sulphur dioxide do not react at any temperature (Schulze, J. pr. [2] 32, 390).— 12. The compounds K_SeBr, and (NH,) SeBr, are produced by dissolving SeO2 in hydrobromic acid and adding potassium or ammonium bromide (v. Muthmann a. Schäfer, B. 26, 1008)

Combinations .- 1. According to Ditte (A. Ch. [5] 10, 82), SeO, combines with dry hydrogen chloride to form two compounds, one of which, SeO2.2HCl, is liquid, and the other, SeO2.4HCl, is solid, at the ordinary temperature. hydrogen bromide SeO 4IIBr is formed, and when this is kept very cold and HBr is passed over it, D. says that SeO, 5HBr is produced. Hydrogen fluoride is said also to combine with SeO2, but the product has not been examined .- 2. With alkali halides the compounds MX.2SeO2.2H2O are formed (Muthmann a. Schäfer, B. 26, 1008).—3. Hinsberg (A. 260, 40) described a compound with alcohol, SeO_2 , C_2H_6O , obtained by evaporating SeO, in absolute alcohol over CaCl .. - 4. Large white crystals of the compound SeO, SO, are obtained by warming ScO, and pure sulphuric anhydride to 100°, distilling off excess of SO, at 60°-70°, and allowing to cool. At 100°

the compound gives up SO₃ (Weber, B. 19, 3185).
Selenion thio-oxide SeSO₃. (Selenion sulphoxide. Selcnion-sulphur trioxide.) Mol. w. not determined. Magnus (P. 10, 491) noticed that Se dissolved in fuming H₂SO, to produce a green solution; Weber (P. 156, 531) separated and analysed the green compound, and gave it the formula SeSO₃. Divers a. Shimosé (C. J. 45, 201) further examined this substance. Powdered Se is placed in liquid SO₃; heat is given off, and a dark-green liquid is formed; after a time the whole solidifies; after warming to 30°-40° for a few minutes the liquid part is drained off, and the adhering SO, is removed by the use of a Sprengel pump (for details v. D. a. S. on TeSO₃, C. J. 43, 324). SeSO₃ is a green solid, which may be heated to c. 35° without change; decomposition begins at c. 40°, and at c. 120° SO, and O are rapidly evolved and Se separates; by heating slowly in vacuo it changes to a yellow powder, which D. a. S. think to be a modification of the thio-oxide. SeSO, is sol. sone, H.SO,; on adding much water Se is ppd., and H₂SeO₂ and H₂SO₂ go into solution. HCl reacts with SeSO₂ in H₂SO₄ to form Se₂Cl₂ and SO₂Cl.OH (v. Selentous chioride, *Preparation*, p. 499). Schulz-Sellack (B. 4, 113) observed that the vapours of SO₂ react with Se to form a yellow powder.

Selenion, oyacids of, and their salts. The oxyacids of So are selenious acid H₂SeO₂ (v. p. 445) and selenic acid H₂SeO₂ (v. p. 435); salts of the thioselenic acids H₂SeSO₂ and H₂SeSO₃ have been isolated (v. p. 484); and salts of the selenosamic acids SeO(NH₂).OH and 2SeO(NH₂).(OH)₂ are known (v. p. 439).

Selenion, oxybromide of. By melting together SeO, and SeBr, Schneider (P. 129, 450) obtained needles which were probably SeOBr, corresponding with SeOCl₂ formed in a similar

Selenion, oxychlorides of. The oxychloride of Se, SeOCl₂, corresponds with sulphuryl chloride SOCl₂; an oxychloride containing Se and S, and corresponding with S₂O₂Cl₄, has also been isolated.

SELENYL CHLORIDE ScOCl₂. (Selenion oxychloride.) Mol. w. not determined.

Preparation.—1. Equivalent weights of SeCl, and SeO₂ are heated in a sealed tube to 150°, and the product is purified by repeated distillation (Weber, P. 118, 615).—2. SeO₂ and PCl₃ are brought together in the ratio SeO₂:PCl₃; SeOCl₂ and POCl₃ are produced, but the heat evolved suffices to cause a secondary reaction, which yields SeCl₄ and P₂O₃, so that very little SeOCl₂ can be obtained by this method (Michaelis, J. Z. 6, 79; cf. Selence chorded, Preparation, p. 439).—3. By distilling SeO₂ and NaCl in the ratio SeO₂:NaCl (Cameron a. Macallan, Pr. 46, 35).

Properties.—A yellowish liquid, fuming in the air, boiling at 179.5°, and solidifying below 0° to colourless crystals, which melt at 10° (M., l.c.).

Reactions and Combinations (M., l.c.).—
1. Water decomposes ScOCl., forming H.SeO.Aq and HClAq.—2. Ammonia produces SeO., Se, N, NH₄Cl.—3. Sulphuryl chloride produces SeOl, and SO₂.—4. Phosphoryl chloride forms SeCl₄ and P₂O₅ (v. Preparation of selenic chloride, p. 439).—5. With phosphorous chloride POCl₃, SeCl₄ and Sc₂Cl₂ are produced.—6. SeOCl₄ combines with stannic chloride to form SScOCl₂.SnCl₄; also with titanic chloride and antimonic chloride to form 2SeOCl₂.TiCl₄ and 2SeOCl₂.SbCl₅ (Weber, P. 125, 325).

Selenion, Thio-oxychloride or, SeSO₂Cl₄. (Pyrothioselenyl chloride. Selenion sulphooxytetrachloride.) Mol. w. not determined.

oxyletrachloride.) Mol. w. not determined.

Formation.—1. By the interaction of SO, and
SeCl. (H. Rose, P. 44, 315).—2. By dissolving
SeCl. in Nordhausen sulphuric acid (Clausnizer,
B. 11, 2007).—3. By heating SO₂Cl₂ and SeOCl₂
in a sealed tube to 170°-180° (C., l.c.).—4. By
the interaction of SO₂OH.Cl and SeO₂, SeOCl₂,
or SeCl₄ (C., l.c.).

Preparation.—SeCl, and SO, OH.Cl are warmed together in the ratio SeCl,:2(SO, OH.Cl) till the SeCl, is quite dissolved:

 $SeCl_1 + SO_2 OH.Cl = SO_2 Cl.OSeCl_1 + Cl.$ (Excess of $SO_2 OH.Cl$ is needed to hasten the reaction and to serve as a solvent.) The reddish solution solidifies on cooling; the white needles are separated by pressing between porous plates, and

dried over H,SO.

Properties and Reactions. - Small white needles; unchanged in vacuo or on gentle warming; deliquesces in moist air; melts at 165° and boils at 183°; V.D. at 209° = 48.5, $SeSO_3Cl_4 = 150$; dissociacalculated for tion has therefore occurred, perhaps thus: $2SeSO_3Cl_4 = 2SO_3 + Se_2Cl_2 + 3Cl_2(C., l.c.)$. Decomposed by water, at once, to H2SO, Aq, H2SeO3Aq, and HClAq.

Selenion, phosphides of; v. PHOSPHORUS

SELENIDES, p. 144.

Selenion, sulphides of. The only compound of Se and S that has been isolated is SeS. Divers a. Shimidzu (C. J. 47, 446) say that this is the only compound of the two elements that exists, but Rathke (B. 18, 1534) considers that others exist, although none but SeS has been obtained in a state of purity. Se and S may be melted together in all proportions, but no compound is produced (Bettendorff a. von Rath, P. 139, 329; Rathke, P. 141, 590). Isomorphous mixtures of the two elements crystallise from solutions of Se and S in Cs₂ (B. a. von R., l.c.). The pp. formed by passing H₂S into H₂SeO₃ contains Se and S in the ratio SeS., but it is a mixture of SeS with S (H. Rose, P. 107, 186; D. a. S., Lc.; Rathke, B. 18, 1534). The pp. containing Se and S in the ratio Se₂S obtained by passing H₂Se into H₂SO₃ is merely a mixture (D. a. S., l.c.).

SELENION MONOSULPHIDE SeS. Mol. w. not determined. Very dilute H₂SeO₃Aq, cooled to 0°-5°, is saturated with H.S, which is first passed through a flask filled with pieces of ice; the yellow pp. which forms is washed, dried in vacuo, moistened with CS2, and allowed to stand for some days till the mass becomes crvstalline, the CS, withdrawing S; CS, is added to the crystals, after a few minutes the CS, is decanted, and the residue is washed with CoH, and then with alcohol. SeS forms small, orangeyellow, lustrous tablets; S.G. 3.056 at 0°, 3.035 at 52°; S.H. 1274. On heating it melts, gives off S vapour, and then vapour of S and Se. Sol. CS., but not crystallisable therefrom by evaporation; insol. water and ether (Ditte, C. R. 73,

625, 660).

Selenion, sulphoxide of; v. Selenion thiooxide, under Selenion oxides, p. 441.

Selenion, sulphoxychloride of; v. Selenion thio-oxychloride, under Selenion oxychlorides,

Selenion, thio-oxide of; v. Selenion oxides,

Selenion, thio-oxychloride of; v. Selenion M. M. P. M. oxychlorides, p. 441. SELENIÓN, ORGANIC COMPOUNDS OF.

Methyl selenide or Selenion methide Me2Sc. Mol. w. 109. (58°). Formed by distilling a Solution of barium methyl sulphate with K₂Se (Wöhler a. Dean, A. 97, 5) or of KMeSO, with Na₂Se (C. L. Jackson, A. 179, 1). Heavy oil with nasty smell. Burns with bluish flame. with nasty smell. Burns with bluish mane.
PtCl, forms (Me₂Se)₂PtCl₄, crystallising from alcohol in yellow plates. Conc. HNO₃ forms (Me₂SeO)HNO₄ [91^o], whence HClAq produces Me₂SeCl₂ [60^o], while HBrAq gives Me₂SeBr₂ [82^o] and KlAq ppts. Me₂SeI.

Methylo-todids Me₂SeI.

Tri-methyl-pclenonium iodide. Yields (Me₂SeCl)₂PtCl₄,

crystallising from water in dark-red octahedra (Jackson, B. 7, 1277).

Di-methyl disclenide Me,Se₂. Formed from KMeSO, and K,Se₂ (W. a. D.; Rathke, A. 152, 211). Heavy reddish-yellow oil, with unpleasant odour, sol. HNO,Aq.

Methane selinic acid CH, SeO, H. [122°]. Formed by oxidising Me2Se2 with HNO3 (W. a. D.). Deliquescent crystals, v. sol. alcohol. Gives with HCl crystalline CH, SeO, Cl. -AgA': prisms.

Ethyl selenide Et₂Se. (108°). (Rathke; Pieverling, A. 185, 381). Oil, without unpleasant odour. HCl added to its solution in dilute HNO₃ ppts. Et₂SeCl₃, whence NH₃Aq forms (Et₂Se)₂OCl₂ (Joy, 4. 86, 35).

Ethyl iodide Et₂SeI. Crystalline. Con-

verted by moist Ag₂O into a strongly alkaline base which forms crystalline salts. - (Et, SeCl) ZnCl

thin plates.—(Ět₃SeCl)₂PtCl₄.

Di-ethyl diselenide Et, Se,. (186°). Liquid with disgusting odour. HCl added to its solution in dilute HNO, gives monoclinic crystals of C₂H₆SeO₂Cl.

Ethane selinic acid Et.SO.H. Yields with

HCl monoclinic crystals of C2HaSeO2Cl.

Ethyl selenhydrate EtSeII. mercaptan. Formed from KSeH and Ca(EtSO,)2 (Siemens, A. 61, 360). Heavy oil, boiling much below 100° and having an unpleasant odour. Reacts with HgO.

Ethyl selenite SeO(OEt)₂. (184°). S.G. 1º 1·49. Formed from Ag₂SeO₃ and EtI, and got also by heating SeOCl2 with NaOEt and dry ether at 180° (Michaelis, A. 241, 158). Thick liquid, miscible with water and alcohol. The chloride SeO(OEt)Cl [10°] (175°), formed from SeOCl, and alcohol, crystallises in needles.

Selenide of carbon CSc. Formed in small quantity by passing a mixture of CCl4 and H2Se through a red-hot tube (Rathke, A. 152, 199). Pungent yellow liquid. Converted by alcoholic potash into EtO.CSe2K, crystallising in yellow needles, v. sol. water and alcohol.

Se(CH₂.CO₂H)₂ Selenido - di - acetic acid Formed from ammonium chloro-acctate and alcoholic $(NH_4)_2$ Se (Ulrich, B. 8, 773). Monoclinic tables. — $\times (NH_4)_2$ A": insol. alcohol -- *CuA": bluish-green pp.

Amide.-Formed from ClCH2.CONH2 and alcoholic (NH₁)₂Se. Prisms, m. sol. cold water.

Di-phenyl selenide SePh₂. S.C. 22 1-450. V.D. 8-17 (calc. 8-09). Formed, together with selenophenol and Se₂Ph₃.C₆H₄Cl (240°-250° in vacuo), from SeCl, and benzene in presence of AlCl, (Chabrié, C. R. 109, 183; Bl. [2] 50, 133; [3] 2, 788). Oil. Boils at 227° under a few cm. pressure. Bromine forms Se(C_eH₄Br)₂ [112°], crystallising from alcohol in colourless hexagonal plates. H2O2, in presence of HCl and a current of air, forms Se(C₆H₄Cl).C₆H₄OH [145°] converted by HNO, into a crystalline product [188°]

Phenyl selenhydrate C.H.SeH. Selenophenol. [60°]. Formed from benzene, SeCl., and AlCl. (Chabrié, C. R. 109, 188; Bl. [3] 2, 788). Sol. alcohol, insol. water.

Tetra - methyl - di - amido - di - phenyl-selenide Se(C.H.NMe₂)₂. [124]. Formed from SeOCl, and di-methyl-aniline in ether (Godchaux, B. 24, 765). Yellowish needles, m. sol. cold alcohol

and ether.—B" H_2SO_4 . [55°]. Colourless needles, v. e. sol. water.—B" $2C_4H_2(NO_2)_3OH$. [135°]. Yellow plates.

Tetra ethyl di amido di phenyl selenide Se(C₈H,NEt₂)₂. [83°]. Formed from SeOCl₂ and PhNEt₂ in ether. Silky needles, v. e. sol. hot ether and alcohol.—B"H₂Cl₂. [73°].—B"2C₆H₂(NO₂)₈OH. [135°]. Yellow plates and needles.

Di-phenyl-selenone SeOPh₂. (230° at 65 mm.). S.G. 19°61 '48. Formed, together with the compound PhSeO(C₆H₄Cl) [94°], from SeOCl₇, benzene, and AlCl₈. Amber-yellow liquid. Not attacked by cold HNO₈. Bromine-water yields SeO(C₆H₆Rr)₂ [120°]. H₂O₂, HCl, and a current of air form SeO(C₆H₄Cl)₂ [159°].

Phenyl seleno-carbimide Ph.NC.Se. Formed by shaking Na₂Se with the chloride of phenyl-carbamine, PhNCCl₂, and ether for a day, filtering, distilling with steam, and drying the oil in vacuo over H₂SO₄ (Stolte, B. 19, 2350). Pale yellowish-red oil, v. sol. alcohol and ether.

Phenyl-seleno-urea NHPh.CSe.NH₂. [182°]. Formed by passing NH₃ into Ph.NC.Se dissolved in ether, and also by the action of H₂Se on phenyl-cyanamide in benzene (Stotte, B. 19, 1579, 2350). Crystals (from alcohol).

Di-phenyl-seleno-urea CSe(NHPh). [186°]. Formed from aniline and phenyl seleno-carbinide (Stolte, B. 19, 2351). Crystals (from alcohol), sl. sol. ether.

Selenaldine C₀H₁₃NSc₂. Formed by passing ScH₂ into an aqueous solution of aldehydeanmonia in absence of air (Wöhler a. Liebig, 4. 61, 11). Colourless crystals, with slight odour, sl. sol. water, v. sol. alcohol and ether. Its solutions are turned brown by air.

Amido-selenazole C₃H₁N₂Se i.e. Se. C(NH₂) N. Selenazylamine. [121°]. CH:CH

CH:CH

Formed by warming seleno-urea with di-chlorodi-ethyl oxide and aqueous NaOEt (G. Hofmanu,
A. 250, 308). White needles, v. sol. alcohol and
ether, m. sol. benzene and water. Decomposed
by prolonged boiling with water.—B'₂H₂PtCl₀:
orange-red pp.

Acetyl derivative C, H, AcN, Se. [c. 210°]. Needles.

Oxy-amido-selenazole Se .C(NH.2) N. Seleno-hydantoin. [190°]. Formed by boiling selenourea with chloro-acctic acid and alcohol (G. Hofmann, A. 250, 312). Thick crystals, m. sol. hot water and alcohol, insol. ether.—B'HCl: needles.

Di-oxy-selenazole Se.C(OH) N. [147°].

Formed by boiling oxy-amido-selenazole with NaOHAq (Hofmann). Prisms, v. sol. alcohol, m. sol. water.

Amido-methyl-selenazole Se.C(NH₂) N.
[80°]. Formed from seleno-urea and chloroacetone (G. Hofmann, A. 250, 305). Needles,
v. sol. alcohol and ether. Alkaline in reaction.
—B'HCl: prisms (from water).—B'₂H₂PtCl₂:

orange-red orystalline pp.

Acetyl derivative C,H,AoN,Se. [122°].

Needles (from benzene), al. sol. water.

Amido-methyl-selenazole carboxylic acid Sc.C(NH₂).

N. [195°]. Formed by heating seleno-urea with chloro-acetoacetic ether (G. Hofmann, A. 250, 309). Needles, m. sol. water, v. sol. alcohol and ether.—HA'HCl: plates, v. e. sol. water.

Acetyl derivative C,H,AcN,SeO₂. [220°]. Needles, almost insol. hot water.
Amido-phenyl-selenazole C,H,N,Se i.e.
Se C(NH.)

Se C(NH₂) N. [132°]. Formed from bromoacetophonone and seleno-urea (G. Hofmann, A. 250, 307). Needles or prisms, insol. water, sol. alcohol and acids.—B'HBr: yellowish plates, sl. sol. cold water.

Di-phenyl-selenazole C₁₅II₁₁NSe i.e.

Se .CPh N. [99°]. Formed from ω-bromoacetophenone and seleno-benzamide (G. Hotmann, A. 250, 31′). Plates, v. sol. alcohol and other. Its salts are decomposed by water.— B'₂H₂PtCl₆: pale-yellow pp.

Phenyl-methyl-selenazole C₁₀H₉NSe i.e. Se .CPh N. (283°) at 737 mm. Formed from PhCSe.NH₂ [126°] and chloro-acetone (G. Hofmann, A. 250, 316). Yellow oil.—B'₂H₂PtCl₆: pale-yellow needles.

Phenyl-methyl-selenazole carboxylic acid Se.CPh N. [207°]. Formed by saponifying its ether, which is got from scleno-benzamide and chloro-acetoacetic ether (Hofmann, A. 250, 318). Small needles (from benzene), m. sol. alcohol.—AgA'.

Ethyl ether Eth'. [1247]. Plates.

Seleno-benzoic acid. Amide C_aH₃.CSe.NH₄.

[1267] Formed by passing H₂Se into an alcoholic solution of benzonitrile made slightly alkaline with NH₃ (Dechend, B. 7, 1273; G. Hofmann, A. 250, 314). Golden needles (from water or ether). Reacts with a-chloro-ketones, forming selenazoles; e.g. X.CO.CHCl.X + CPh(SeH):NH

= H₂O + Se.CPh

NHCl.

Seleno-benzoic aldehyde v. Benzylidene selenide.

Selenocyanic acid HSeCN. The K salt is got by fusing K,FeCy_a (3 pts.) with Se (1 pt.) (Crookes, A. 78, 177; cf. Berzelius, S. J. 31, 60). The free acid is obtained, in solution, by decomposing the lead salt by H.S. It is decomposed by acids into Se and HCy. FeCl₂ does not give a red colour, but ppts. Se. Iodine added to a solution of KSeCN ppts. KC₂N₃Se₄. Air containing a little chlorine passed over a 10 p.c. solution of KSeCN forms a red crystalline pp. KSe₂C₃N₃ aq changing to yellow Se₂Cy₂, which separates from chloroform in yellow plates, and is decomposed by water into HCy, SeO₂, and Se₂ and yields in vacuo at 108° a crystalline sublimate of Se₂Cy₂, decomposed by hot water into HCy, SeO₃, and Se (Verneuil, C. R. 103, 144). Alcohol converts KSe₂C₃N₃ into Se and KSe₂O₃N₃ which forms brown crystals, sol. alcohol.

Salts.—KA'. Formed as above, and also by dissolving Se in aqueous KCy (Wöhler; Schiellerup, A. 109, 125; G. Hofmann, A. 250, 296). Very deliquescent needles, alkaline to litmus.—NH,A' (Oameron a. Davy, C. N. 44, 68).—KA'HgCl₂: white pp.—KA'HgBr₂.— KA'HgL₂.—KHg₂A'₂: prisms.—KHgA'₂.—Hg₂A'₂: olive-green pp.—HgA'₂: felt-like mass of yellowish crystals.—AgA'₂-HgCl₂.—PbA'₂: lemonyellow needles (from water).—K₂PtA'. Dark-red scales (Clarke, B. 11, 1325).—AgA'. Satiny crystals, blackened by light. Converted by ICy into volatile crystalline SeCy, (Linnemann, A. 120, 36).

Methyl ether MeA'. (158°). Yellow oil

(Stolte, B. 19, 1577).

Allyl ether C.H.A'. Oil.

Methylene ether CH.A'. [132°]. Formed from MeI and alcoholic KSeCN (Proskauer, B.

from Met and alconoloc KSeCN (Prostauer, B. 7, 1281). Rhombohedra (from alcohol). HNO, forms $\mathrm{GH}_2(\mathrm{SeO}_2\mathrm{H})_2$.

Ethylene ether $\mathrm{C}_2\mathrm{H}_4\mathrm{A}'_2$. [128°]. HNO, forms, on boiling, deliquescent $\mathrm{C}_2\mathrm{H}_4(\mathrm{SeO}_3\mathrm{H})_2$. which yields BaA'' , sol. hot water. KOH yields distribute the scheme of the scheme

diethylene tetraselenide [131°].

Propylene ether CH₂.CH(SeCN).CH₂(SeCN). [66°]. Formed by heating KSeCN with propylene bromide and alcohol (Hagelberg, B. 23, 1091). White crys-

Trimethylene ether CH2(SeCN).CH2.CH2(SeCN). [51°]. Converted by KOH into trimethylene diselenide [55°].

Benzyl ether v. vol. i. p. 502. Selenocyano-acetic acid CH₂(SeCN).CO₂H. [85°]. Formed from chloro-acetic acid and potassium selenocyanide (G. Hofmann, A. 250, 800). Yellowish needles (from ether and chloroform), v. e. sol. water and alcohol.—BaA',: amorphous.

Selenocyano-acetoacetic ether

CH₂.CO.CH(SeCN).CO₂Et. Formed from chloroacetoacetic ether and KSeCN (H.). Liquid.
Selenocyano-acetone CH₃, CO.CH₃, SeCN.

Formed from chloro-acetone and KSeCN (H.). Yellowish oil. Gives an oily phenyl-hydrazide and an oxim. Not more sol. alkalis than water.

Selenocyano-acetophenone

CaHa.CO.CH2SeCN. [85°]. Formed by boiling w bromo-acetophenone with alcohol and KSeCN (Hofmann). Ĉrystalline.

Selenocyano-ethyl-phthalimide

C.H.O.: N.CH2.CH2.SeCN. [125°]. Formed by heating bromo-ethyl-phthalimide with KSeCy and alcohol (Coblenz, B. 24, 2133). Crystalline mass. Converted by boiling dilute caustic potash into Solvered by bolling dutte causate potash into Se₂(C₂H₁,NH.CO.C₆H₁,CO₂H)₂ [119°], which forms yellowish crystals and is converted by HCl at 180° into Se₂(C₂H₁,NH₂)₂, which yields B"2HCl [188°] and B"2C₆H₂N₂O, [178°], both being crystalline.

 γ -Selenocyano-propyl-phthalimide C₂H₄O₂:N.CH₂.CH₂.CH₂.SeCN. [102°]. Formed by heating bromo-propyl-phthalimide with KSeCN and alcohol (Coblenz, B. 24, 2134). Converted by boiling dilute (10 p.c.) KOH into crystalline Se₂(C,H₂,NH.CO.C,H₂,CO₂H), [94°], whence HCl at 180° forms Se₂(C,H₂NH₂)₂, which yields B"2HCl [170°] and B"2C₂H₂N₂O₇ [165°].

ω-Selenocyano-o-toluic acid. Nitrile CH₂(SeCN).C₂H₃.CN. o-Cyano-benzyl seleno-cyanide. [121°]. Formed by warming the ni-trile CH₂Cl.C₃H₄.CN with KSeCN (Drory, B. 24, 2564). Long brownish needles (from alcohol) or prisms (from benzene). Converted by dilute

H.SO, into Se (CH, C, H, CN), [110°]. HCIAq at 100° forms Se and o cyano bensyl chloride.

Selenceyanuric acid H.Se,C,N, Formed from Cl₃Cy, and Na₂Se (Stolte, B. 19, 1578).

Methyl ether. [174°].

Seleno-phthalimidine C.H. CH. Se.
Formed from OH. (SeCN). C.H. CN and conc.
H.SO. (Drory, B. 24, 2566). Sol. alcohol.
Reactions.—1. NaOH forms the compound

Se₂(CH₂C₆H₄.CN)₂, crystallising in needles [110°], sol. alcohol and CS₂, and converted by HCl at 160° into Se and phthalide.-2. When steam is blown through a mixture of selenophthalimidine, alcohol, and KOH there is formed selenophthalide C_sH₄ CO Se, crystallising in broad plates [58°], insol. water, sol. alcohol.—3. Alcoholic potash and MeI form CH₂(SeMe).C₈H₄.CN (180°-200°).

Salts.—B'HCl: needles, slightly sol. water and alcohol.—B',H,PtOl,. Orange powder.—B'C₄H₄N₃O₅.—B'HBr. [264°]. Needles: sl. sol. water.—B'HI₂ (?) [223°]. Formed by heating CH₂(SeCy).C₅H₄,CN with HIAq at 100°. Darkviolet needles. Sulphate [145°-150°].

Piaselenole C_oH₄<N Se. [76°]. Formed

from o-phenylene-diamine and an aqueous solution of selenious acid (Hinsberg, \hat{B} . 22, 2897). Needles, v. sol. alcohol and ether, sl. sol. water. Its salts are yellow and decomposed by much water with separation of the base. Iodine forms a green periodide.

Amido-piaselenole C.H.(NH.):N.Se. [150°]. Formed by adding H.ScO, to a cool solution of tri-amido-benzene hydrochloride and NaOAc (Hinsberg, B. 22, 2898). Brownish-red needles, sl. sol. water, m. sol. alcohol. SnCl, separates Se. -B'HCl: reddish-brown needles, sl. sol.

Oxy-piaselenole. Ethyl derivative C_sH₃(OEt):N₂Se. [104°]. This is formed from $C_8H_3(OEt)(NH_2)_2$ and aqueous H_2SeO_3 . Needles torming a yellowish-red solution in H_2SO_4 .

Methyl-piaselenole CH .CH:C.N Se. [73°]. (267° uncor.). Formed from tolylene-diamine and aqueous SeO₂ at 80° (Hinsberg, B. 22, Needles, sl. sol. cold water. SnCl. yields tolylene-o-diamine and Se. Does not react with nitrous acid or with Ac₂O.—B'₂H₂PtCl₆.
Chloro-methyl-piaselenole C₆H₂ClMe:N₂Se.

[150°]. Formed by warming o-tolylene-diamine with SeO₂ and conc. HClAq (Hinsberg, B. 23, 1395). Small needles, volatile with steam.

Naphthopiaselenole C.H. CH:C.N Se.

[129°]. Formed from (aß)-naphthylene-diamine sulphate, aqueous NaOAc, and SeO2 (Hinsberg, B. 22, 866). Needles, sl. sol. water, m. sol. alcohol, v. sol. ether. Conc. H. SO, gives an intense yellow colour. SnCl₂ and HCl give Se and naphthylene-diamine.

Seleno-urea CSe(NH₂)₂. [c. 200°]. S. 11 at 19°. S. (alcohol) 3 at 18°. Formed by passing H.Se into a 2 p.c. solution of cyanamide in ether (Verneuil, C. R. 99, 1154; 100, 1296; Bl. [2] 43, 58, 583). White needles, v. sol. hot water, sl. sol. alcohol and ether. solutions are decomposed by light, especially in presence of an alkali, with separation of

selenium. In presence of air and HClAq it yields (CSeN2H4)2O2HCl, which forms brown orystals with violet reflex, converted by barytawater into Se, seleno-urea, and cyanamide. The compound (CSeN.H.), 02HBr may be formed in like manner. When the 'oxy-triselenourea' hydrochloride is allowed to stand in the acid liquid in which it is formed, it changes into yellow crystalline (CSeN₂H₄)₂Cl₂. H1Aq converts selenoures into (CSeN₂H₄)₂I₂. H₂SO₄ added to a saturated solution of selenourea forms scarlet crystals converted by heating with alcohol (100 pts.) and H₂SO₄ (4 pts.) at 50° into (CSeN₂H₄)₂OH₂SO₄, crystallising in pearly plates. Ethylene-\psi-seleno-urea C3H6N2Se i.e.

CH-Se C:NH. Formed by evaporating a solution of bromo-ethyl-amine hydrobromide (8 g.) with KSeCy (5 g.) to dryness on a water-bath (Baringer, B. 23, 1003). Unstable. Converted by bromine-water into ethylene-\u00fc-urea.-B'HBr. [170°]. Needles B'C₈H₂N₁O₇. [220°]. Needles. Needles. - B'2H2PtCls.

Propylene-ψ-selenourea C,H,N,Se. Obtained in like manner from β-bromo-propyl-amine. B'C,H,N,O, [110°].-B'2H,PtCl. Light-yellow

plates.

Trimethylene - ψ - selenourea C,H,N,Se. Formed from γ -bromo-propyl-amine and KSeCy.—B'HBr. [135°]. White crystals (from alcohol) soon turning red.—B'C₆H₃N₃O₇. [c. 53°]. Small concentric needles.

Seleno-isovaleric aldehyde $C_aH_{10}Se$. [57°].

Crystalline (Schröder, B. 4, 402).

nstalline (Schroder, D. 4, 202). Di-methyl-selenophene Se CMe:CH

Selenoxene. (154° uncor.). Formed by heating acetonyl-acetone with phosphorus pentaselenide P2Se, at 180°. Colourless mobile liquid of slight smell. With isatin and conc. H2SO, it gives a carmine-red colouration. By Laubenheimer's reaction a reddish-brown colour is produced. Benzoyl-formic acid also produces a reddish-brown colouration (Paal, B. 18, 2255).

SELENIOUS ACID H.SeO. Mol. w. not determined. This compound is the acid of the

anhydride SeO₂.

Preparation.—Se is dissolved in hot conc. HNO, Aq, the solution is evaporated to dryness, the residue is dissolved in water, BaOAq is added to ppt traces of H₂SeO₄, the filtrate is evaporated to dryness in a retort, and the residue is heated till SeO, sublimes (Thomsen, B. 2, 598); the pure SeO, thus obtained is dissolved in c. i its weight of hot water, on cooling large crystals of H.SeO, separate (Weber, P. 118, 479). To prevent formation of H.SeO, in the oxidation of Se, Divers a. Shimosé (C. J. 47, 439) recommend to dissolve Se in a large excess of conc. H2SO, instead of using HNO.

Properties .- Large white crystals, resembling nitre; effloresces in air; withdraws water from moist air; S.G. 3.0066 at 15.7° (Clausnizer, B. 11, 2009). Poisonous. The acid crystallises unchanged from solution in aqueous acetic acid, or in aqueous C_sH₆ (Chabrié, A. Ch. [6] 20, 202). H.F. [Se,O²,Aq] = 56,160 (Th. 2, 274). H,SeO₂ is a dibasic acid; this is shown by the existence of two salts M'HSeO, and M'2SeO, (v. SELENITES), and also by the heat of neutralisation, which is given by Thomsen (Th. 1, 172) as follows: this vol. p. 145.

 $[H^2SeO^3Aq, NaOHAq] = 14,770, [H^2SeO^3Aq]$ 2NaOHAq] = 27,020, [H*SeO*Aq, 4NaOHAq, = 27,480. As no derivative of H₁SeO₂ exists corresponding with C.H. SO.OH, and as only one ethyl selenite SeO(OEt), can be obtained, and as the compound SeO.Cl.OEt has been isolated, it appears that the acid is SeO(OH), and not SeO, OH.H (Michaelis a. Landmann, B. 13, 656; A. 241, 150).

Reactions.—1. Heat causes H.SeO, to decompose to SeO, and H.O.—2. Many oxidisable bodies remove O from H.SeO. For instance, sulphur dioxide passed into H.SeO. Aq ppts. Se; the reduction is complete only when the compounds interact in the ratio H.SeO,:280, (Schulze, J. pr. [2] 32, 390); the presence of HCl hastens the reaction (v. Michaelis, J. Z. 6, 88; Rathke, A. 152, 194). When SO2 and H.ScO, interact in other proportions than H₂SeO₃:2SO₂, thioselenic acids are formed (cf. p. 435). Hydrogen sulphide ppts. Se and S in the ratio Se:2S (Divers a. Shimidzu, C. J. 47, 441). Various metals, such as Cu, Fe, Ag, or Zn, also reduce H2SeO3Aq in presence of HCl, with ppn. of Se. H2SeO3Aq is partly reduced by exposure to air containing dust. M. M. P. M.

of selenious acid SELENITES. Salts of selenious acid (H,SeO₃), M₂ISeO₃, and MIHSeO₃. The alkali salts are formed by adding alkalis to H.SeO.Aq and evaporating; most of the other selenites are formed from the alkali salts by double de-

composition.

Selenites give selenides, or metallic oxide and Se, when heated with charcoal. Heated with NH,Cl, out of air, they give a sublimate of Se. Most selenites, except those of the alkalis, are insol. in water.

Many selenites combine with SeO2 to form acid salts; many basic selenites are also known.

Boulzoureano (Bl. [2] 48, 209) found that many selenites can be obtained in well-formed crystals by adding Na, SeO, Aq to solutions of metallic salts, and heating the pp. so formed with very dilute H2SeO2Aq in sealed tubes at 200°; also by dissolving metallic carbonates in dilute H_2SeO_3Aq , adding water, and heating in sealed tubes at 200°. The older investigations of selenites were by Berzelius (v. Lehrbuch) and Muspratt (C. J. 2, 52). Boulzoureano (l.c.; also A. Ch. [6] 18, 289) has made a more thorough investigation of these salts. Nilson (Bl. [2] 21 253; 23, 260, 353, 494) has also prepared and described many selenites.

It has been thought sufficient to give the names of the metals selenites of which have been analysed. Abstracts of B.'s papers will be found in C. J. 54, 220; 60, 262; and an abstract of Nilson's paper will be found in the 3rd Supp. of the first edition of this DICTIONARY, p. 1786. Al, Am, Sb, Ba, Be, Bi, Cd, Ca, Ce, Cr, Co, Cu, Ai, Aii, Se, La, Pb, Li, Mg, Mn, Hg (cf. Cameron B. Davy, *Trans. I*, 28, 146), Ni, K, Ag, Na, Sr, Tl, Th, U, Zn. M. M. P. M. Tl, Th, U, Zn.

R. 11P. Se. v. Phosphorous selenide, p. 145. SELENOSAMIC ACIDS, SALTS OF. Selenosamic acid SeO(NH2)OH has not been isolated, but the NH, salt of this acid, and also the NH, salt of diselenosamic acid, 2SeO(NH2).(OH)2, have been obtained.

Ammonium selenosamate SeO(NH2)ONH1 is formed by the action of dry NH, on SeO, dissolved in alcohol. It is a wine, conditioned deliquescent salt; very unstable, easily giving disclenosamate. Water solved in alcohol. It is a white, crystalline, off NH, and forming diselenosamate. partially converts this salt into (NH₄), SeO₃.

Ammonium diselenosamate 2SeO(NH₂).OH.ONH₄ is formed by boiling an alcoholic solution of the selenosamate, or by letting the solution stand over HoSO, in vacuo. It crystallises from alcohol in large, deliquescent prisms (v. Cameron a. Macallan, Pr. 44, 112). M. M. P. M.

SEMINOSE v. MANNOSE.

SENEGIN v. SAPONIN.

SENNA v. CATHARTIC ACID.

SENNITE is identical with PINITE, the methyl ether of dextrorotatory inosite.

SEPTYL. A name for HEPTYL.

SEQUOIENE $C_{13}H_{16}$. [105°]. (290°-300°). V.D. 5·66 (obs.). Occurs, together with $C_{10}H_{16}$ (155°), S.G. 16 ·852, [α]_D = 24°, and oily $C_{18}H_{20}O_3$ (229°), in the leaves of Sequoia gigantea (Lungo a. Steinkauler, B. 13, 1656). White plates with characteristic smell, volatile with steam; sol. alcohol, ether, benzene, and chloroform.

SERICIC ACID C₁₅H₃₀N₄O₇. Formed by the action of conc. baryta-water on silk (Champion, C. R. 72, 330). Deliquescent, translucent mass.

BAA',... PbA',: pp.
SERIN 0,H,NO, a-Amido-hydracrylic acid?
8.8 at 10°; 5 at 20°. Formed by boiling silk with dilute H.SO₄ (Crämer, J. pr. 96, 76; Barmann, B. 15, 1735; Melikoff, C. C. 1881, 354). Monoclinic crystals, insol. alcohol and ether. Converted by nitrous acid into glyceric acid.-CuA'₂.—HA'HCl: needles, v. e. sol. water.— HA'HNO₃: minute needles.

SERINE v. PROTEÏDS.

SERUM ALBUMEN v. PROTEÏDS. SERUM CASEIN v. PROTEÏDS. SERUM GLOBULIN v. PROTEÏDS.

SESAME OIL. S.G. 20 9191. $\mu_{\rm D} = 1.474$ at 20° (Long, Am. 10, 392). A fatty oil obtained from the seeds of Sesamum orientale. It contains glycerides of oleic and linoleic acids (Pohl, J. pr. 63, 400; Hazura a. Grüssner, M. 10, 247). Gives a raspberry-red colour on warming with HClAq and cane-sugar (Zipperer, Chem.

Zeit. 11, 1600). The oil contains 05 p.c. of sesamin C₁₈H₁₈O₃ [118]. S. (alcohol) ·27 at 20°; 8·07 at 78°. S.G. 1·305. H₂SO₄ containing HNO, colours sesamin green and afterwards bright red (Tocher, Ph. [3] 23, 700).

SEXTYL. Another name for HEXYL.

SHEA BUTTER, obtained in West Africa from the nuts of Bassia Parkii, contains ole in and stearin (Oudemans, J. pr. 89, 205).

SHELLAC v. LAC.

SHIKIMIC ACID C, H10O, i.e.

СH(OH)<СH(OH).СН СH₂.СH(OH) >С.СО₂H. [184°]. S.G. 14 1.599. $\mu_{\infty} = 1.303$ at 14°. $[a]_{D} = -186^{\circ}$ in a 7 p.c. solution. S. (ether) 015 at 23°; S. (alcohol) 2.25. Occurs in the fruit of *Illicium* religiosum (Japanese, shikimi) and Chinese star-anise (Eykman, R. T. C. 4, 49; 5, 299; B. 24, 1278). Crystalline powder composed of minute needles, sl. sol. alcohol and CHCla nearly insol. ether. Levorotatory. Yields poxy-benzoic acid when heated with HClAq. NH, A': crystals.

Dihyďride

 $CH(OH) < CH(OH) \cdot CH_2 > CH \cdot CO_2H$. [175°]. S.G. 2 1·47. $\mu_{00} = 1.324$ at 19°. $[a]_{D} = -18^{\circ}$. S. 14 in the cold. Formed by reducing the acid with sodium-amalgam in presence of HClAq. Monoclinic crystals. Converted by HCl into benzoic acid.

Dibromide

CH(OH).CHBr CBr.CO₂H. [c. 188°] $\mu_{\infty} = 1.295$. [a]₀ = -58° . Formed by adding Br to a cold solution of the acid. Tetrahedra. Converted by moist Ag₂O into C, H_BBrO, [235°], S. 6·3 at 17°, $[\alpha]_D = +22^\circ$, crystallising in hexagonal needles, sl. sol. other, converted by baryta into oxyshikimic acid [156°]

SHIKIMIPICRIN C,H,,O, (?). [200°]. S. 6.2 in the cold. Occurs in the fruit of Illicium religiosum (Eykman, R. T. C. 4, 53). Large

crystals, m. sol. alcohol, sl. sol. ether.

SHIKIMOLE v. SAFROLE. SIEGBURGITE. A fossil resin found near Siegburg. It contains styracin, metastyrene, and some free cinnamic acid (Klinger a. Pitschke, B. 17, 2742).

SIKIMINE. [175°]. A poisonous substance in the seeds of Illicium religiosum (Eykman,

Ph. [3] 11, 1046). Prisms, al. sol. water, ether, and CHCl₁, v. sol. alcohol and HOAc.

SILICA SiO₂. (Silicon dioxide. Silicic anhydride.) Mol. w. not known. S.G. quarts 2:647 to 2:652, tridymite 2:282 to 2:326, amorphous 2.20 at 15.6° (Schaffgotsch, P. 68, 147). S.H. quartz 1787 at ord temp., 305 at c. 400°, constant from 400° to over 1000° (Pionchon, C. R. 106, 1344). H.F. [Si,O'] = 219,240 from amorphous Si; 211,120 from crystalline Si (Troost a. Hautefeuille, C. R. 70, 252).

Occurrence.-Compounds of SiO2 are very widely distributed in large quantities; quartz, flint, chalcedony, jasper, opal, &c., are nearly pure SiO. Silica is the chief constituent of sandstones; felspar, agate, and a vast number of other minerals contain silica. Silica (or silicates) is also found in many plants.

Preparation.—(i) Amorphous silics.-1. Quartz is finely powdered, best by heating to SILICA.

redness and plunging into cold water, and heated with c. 6 times its weight of Na₂CO₃ in a Pt orucible till the whole fuses quietly; the cold mass is treated with water, the solution, when clear, is poured slowly into excess of fairly cone. HClAq, the liquid (after filtration, if necessary) is evaporated to dryness in a Pt dish, the residue is moistened with cone. HClAq, warmed, and allowed to stand for an hour or two; this treatment with acid is repeated two or three times; water is then added and, after warming and standing, the solution is filtered off, the residual SiO₂ is washed with hot water, dried, and heated to rodness.—2. SiF₄ (o. p. 459) is passed into water, the gelatinous SiO₂ which is ppd. is pressed between linen, thoroughly washed, dried, and heated to redness.

(ii.) Crystalline silica.—1. Moist ppd. SiO₂—e.g. the pp. got by passing SiF, into water-is dissolved in boiling NaOHAq, and the solution is heated in a sealed tube; crystals of tridymite (v. infra, Properties) separate below 180°, and crystals of quartz separate above 180° (Maschke, P. 145, 549) .- 2. Small tubes of hard glass are half-filled with solutions of dialysed silicic acid (v. Silica, hydrates of, infra) containing c. 10 p.c. SiO₂, closed by fusion, and heated to 250° for some months; small crystals of quartz are thus obtained (Kroustchoff, C. R. 104, 602).-3. Any hydrate of SiO2 yields crystalline silica by heating in a forge-fire (Fremy, A. Ch. [3] 38, 327).—4. Crystalline SiO₂ is formed by fusing silicates with microcosmic salt (G. Rose, J. pr. 101, 228), or with borax (G. Rose, B. 2, 388). For other methods of preparing crystalline silica v. Rammelsberg (B. 5, 1006), Hautefeuille (C. R. 86, 1133; 90, 830), Sénarmont (A. Ch. 42, 129), Friedel a. Sarasin (Bl. [2] 31, 481), and Daubrée (Ann. M. [5] 12,

Properties.—The mol. w. of silica is unknown, but there is reason to think it is a considerable multiple of that indicated by the formula SiO₂. By applying the cryoscopic method to an aqueous solution of colloidal silicio acid (v. Metasilicio acid, infra) Sabanéeff (J. R. 21, 515; Abstract in C. J. 58, 1215) obtained numbers pointing to silica being a very high polymeride of SiO₂. The great infusibility and non-volatility of silica, especially when this compound is compared with CO₂, make it probable that the molecular formula of silica is nSiO₂, where n has a large value (v. Mendelceff's Principles of Chemistry, vol. ii. p. 93).

Orystalline silica. SiO₂ crystallises as guartz in colourless, transparent, hexagonal, six-sided prisms having the axes-ratio 1:1·0999 (S.G. c. 2·65), and as tridymite in hexagonal forms with the axes-ratio 1:1·631 (S.G. c. 2·3). Crystalline SiO₂ is insol. or almost insol. in alkali solutions; it is attacked by HFAq slowly and without notable rise in temperature.

Amorphous silica is a white, loose, tasteless powder; S.G. 2.2. It dissolves in hot alkali solutions; after continued heating to a high temperature it is less sol. or nearly insol., owing to change into the crystalline form. Dissolves in HFAq, with intumescence and considerable rise of temperature.

Silica is fusible in the O-H flame to a

colourless glass; when fused it may be drawn into extremely fine threads. Cramer (Zeit. fitr angewand. Chem.) finds that quartz is volatile at a temperature whereat Pt boils (v. Abstract in C. J. 64, ii. 164). SiO, is insol. in acids, except in HFAq. It is slightly volatilised in steam (v. Jeffreys, A. 39, 255). Silica is insoluble in molten microcosmic salt (NaNH, HPO).

Reactions.-1. Fused with alkalis, alkali silicates are formed; with alkali carbonates CO, is evolved.—2. Decomposes most solid salts by fusion with them with formation of silicates (cf. Silicates, p. 448). According to Mills a. Meanwell (C. J. 39, 533) SiO₂ does not react with pure Na, SO, or K, SO, even at a very high temperature.—3. SiO, is decomposed by potassium at a red heat, forming K silicate and silicide; it is also reduced at red heat by calcium. strontium, and magnesium (Bunsen a. Matthiessen, A. 94, 111; Phipson, Pr. 13, 217; Parkinson, C. J. [2] 5, 128; Winkler, B. 23, 2642).—4. Heated with carbon and certain metals, SiO₂ is reduced, with formation of silicides of the metals; Ir, Pd, Pt, and Ru react in this way (Boussingault, C. It. 82, 591; cf. Warren, C. N. 60, 5). Au and Ag reduce SiO, only when strongly heated therewith in presence of Na₂SiF₈ and Na (W., l.c.).—5. Dry SiO₂ (prepared from SiF.) which has not been strongly heated reacts with molten metaphosphoric acid to form SiO, P,O, and SiO, 2P,O, 4H,O (Hautefeuille a. Margottet, C. R. 96, 1052; 104, 56; v. Silico-риозгнови охибея, p. 462).—6. Mixed with finely divided carbon and heated in hydrogen sulphide, SiS, is formed (v. Silicon sulphide, p. 462).-7. A mixture of SiO, and carbon heated in chlorins or hydrogen chloride gives SiCl, and CO (v. SILICON TETRACHLORIDE, p. 458); when bromine or hydrogen bromide is used, SiBr, is formed (v. Silicon tetrabromide, p. 457).—8. With hydrogen fluoride, SiF, is obtained (v. Silicon TETRAFLUORIDE, p. 459). -9. Heated to low redness in vapour of boron trichloride, SiCl, and B2O3 are formed (Troost a. Hautefeuille, A. Ch. [5] 7, 476).

SILICA, HYDRATES OF. (Silicic acids.) The hydrates of SiO₂ act as weak acids. The compositions of these hydrates are very uncertain. The silicates nSiO₂, mRO are derivable from hydrates of SiO₂, some of which have been isolated while others are hypothetical (v SILICATES, p. 448).

METABLICIC ACID H₂SiO₂ = SiO₂.H₂O. (Silica monohydrate.) Obtained by the action of moist air on Si(OEt)₁; Si(OEt)₁+3H₂O = SiO₂.H₂O + 4EtOH (Ebelmen, J. pr. 37, 359). Also by dialysing a mixture of Na silicate and excess of HClAq until the liquid in the dialyser is free from chlorides, concentrating by boiling in a flask, allowing to gelatinise, and drying the jolly-like mass over H₂SO₄ for two days (Graham, T. 1861. 183). SiO₂.H₂O is described by Graham as a transparent, glassy, lustrous solid; insol. water.

ORTHOSILICIO ACID H₄SiO₄ = SiO₂.2H₄O. (Silica dihydrate.) This hydrate of SiO₂ has not been isolated with certainty; it is supposed to exist in the solution obtained by dialysing a solution of K or Na silicate with excess of HClAq; but as the compositions of the silicates of K and Na are very doubtful, the argument

based on the supposition that these silicates are ortho- salts—and, therefore, will yield ortho- acid—is not very trustworthy. Various esters of the form Si(OX), exist where X is Me, Et, &c. The solution of SiO, xH₂O, when x is supposed to —2, obtained by dialysing K or Na silicate solution with excess of HClAq till the liquid in the dialyser is free from chlorides, is described by Graham (l.c.) as a clear liquid, which may be boiled in a flask till it contains c. 13 p.c. SiO, without separation of any solid. The liquid soon becomes opalescent on keeping, and after a time sets to a transparent, colourless jelly, which is insol. water, and, dried over H2SO4, gives SiO2H2O (v. METABLLICIC ACID, p. 447). The solution of SiO2xH2O is coagulated by a minute trace of an alkali or alkaline earth carbonate, also by CO,, but not by dil. H. SO, Aq, HNO, Aq, or H.C. H., O. Aq. The solution reddens litmus (cf. Doveri, A. 64, 256; Liebig, A. 94, 373; Karsten, P. 6, 357; Fuchs, A. 82, 119; Struckmann, A. 94, 341; Rose, P. 108, 20; Kühn, J. pr. 59, 1; Fremy, A. Ch. [8] 88, 314; Maschke, J. pr. 68, 234).

Trisilicic Dihydrate $3SiO_2H_2O = H_4Si_3O_8$.

By decomposing K or Na silicate solution by CO, or SiF, by H.O, and drying the gelatinous pp. so formed in vacuo, Fremy (l.c.) obtained a hydrate containing 16.2 to 16.8 p.c. water (3SiO₂.2H₂O requires 16.67 p.c. water). Several naturally occurring silicates may be regarded as derived from this hydrate (v. SILICATES,

infra).

DISILICIO MONOHYDRATE 2SiO₂.H₂O = H₂Si₂O₃. The gelatinous pp. formed by decomposing SiF₄. by water, after drying for six weeks in air at 20°-25°, was found by Merz (J. pr. 99, 1771) to contain from 13.1 to 13.5 p.c. water (the formula

given requires 13.05 p.c. water).

OTHER HYDRATES. By drying the gelatinous pps. obtained by decomposing SiF, by water, or by decomposing alkali silicate solutions by weak acids and washing (v. Kühn, J. pr. 59, 1), solids are obtained of varying and uncertain composition (v. Carnelley a. Walker, C. J. 53, 80); hydrates of fair definiteness agreeing approximately with the formulæ 3SiO₂H₂O = H₂Si₂O₃, 9SiO₂2H₂O = H₄Si₂O₃, and 6SiO₂H₂O = H₂Si₂O₃, have been obtained (Fuchs, A. 82, 119; Gotthave been obtained (Fuchs, A. 82, 119; Gottlieb, J. pr. [2] 6, 185; Merz, J. pr. 99, 1771). For methods of preparing gelatinous pps. of SiO, xHO v. Struckmann, A. 94, 337; Kuhlmann, A. 41, 231; Liebig, A. 94, 374; Guyton-Morveau, A. Ch. [2] 31, 246; Hautefeuille a. Margottet, C. R. 96, 1052. Concerning the absorption of water by SiO v. van Bemmelen R. sorption of water by SiO, v. van Bemmelen, B. 11, 2232; 13, 1466.

Thomsen (Th. 1, 215) has examined the thermal phenomena accompanying the interaction of NaOHAq and SiO2Aq; the SiO2Aq was prepared by adding exactly an equivalent of HCl in dilute solution to Na silicate solution of known composition. He gives the following

tables :-

m	[mNaOHAq,SiO*Aq]	· #	[NaOHAq.xSiO*Aq
ì	2652	1	1353
į	3241	Ī	2615

There seems to be no fixed point of neutral-

Putting [NaOHAq,xSiO²Aq] = x.O isation.

where C and n are constants having the values C=13,410 and n=2.13, the calculated values agree very fairly with the observed so far as data go; if the formula is supposed to be accurate then the heat of neutralisation of SiO_2Aq , when SiO_2 is taken as $= \infty$ in the reaction NaOHAq + SiO2Aq, is = 13,410, which is about the thermal value of the interaction of an acid with one molecular weight of NaOH. affinity of SiO2Aq is almost nil. M. M. P. M.

SILICATES. Compounds of SiO, with basic radicles. The basic radicles of silicates are generally oxygen-containing groups; sometimes they contain negative elements other than O. Silica, like other feebly acidic oxides, combines with bases in many proportions, forming compounds which may be represented as normal salts, and also compounds of the type of basic and acidic salts. The general composition of silicates is given by the formula $nSiO_2mR$, where R = basic radicle. Most of the silicates occurring in rocks vary in composition between the limits SiO, 4MO and 2SiO, MO, where M = a mono- or di-valent metal, and the limits $SiO_2.2M_2O_3$ and $6SiO_2.M_2O_3$ where M=a trivalent metal. The metals most commonly found in these silicates are Al, K, Na, Ca, Mg, Fe, and Mn. A fair number of natural silicates contain Cl or F as part of the basic radicle. Few pure silicates occur in rocks: the siliceous minerals are generally mixtures of isomorphous silicates; hence it is not possible to deduce satisfactory formulæ for naturally occurring silicates solely from the results of analyses of minerals.

Mendeléeff (Principles of Chemistry, 2, 111) compares the siliceous minerals to alloys. Several silicates which occur as mineral species have been formed artificially; the study of the altera-tion-products of natural silicates, and the comparison of silicates with carbon compounds (v. e.g. Mendelceff, l.c., note p. 111) throw light on the constitution of these bodies.

The most important memoirs on the constitution and chemical relations of the silicates are to be found in Groth's Tabellarische Uebersicht der Mineralien nach ihren Krystallographischchemischen Beziehungen (3rd ed.), pp. 89 et seq., and in a series of papers by F. W. Clarke (Am. 10, 120; Am. S. [3] 38, 384; 40, 303; 43, 190), (v. also Clarke in U.S. Geological Survey Bulletins, No. 90 [1892]; also A. C. J. May 1893).

Groth and Clarke both look on the natural silicates as derived from a few fairly simple types. They are very stable compounds; most of them are formed at high temperatures, their number is not very great, and a few typical forms containing a small number of common metals are very widely distributed. Among the commoner silicates are SiO₂2MO, 2SiO₂8MO, SSiO_2MO, where M is very frequently an alkaline earth metal; 3SiO_2R_2O_3, 2SiO_2R_2O_3, 6SiO_2R_2O_3, M_2O, and 3SiO_2R_2O_3, 3MO, where R is Al or Fe, and M is K, Na, or an alkaline earth.

The consideration of the probable constitution of the typical silicates may be approached by seeking to derive these salts from the silicia acida nSiO₂·mH₂O. Metasilicic acid, SiO₂·H₂O, has been isolated; the formula may be written H₂SiO₂ or OSi(OH)₂. Orthosilicic acid, SiO₂·2H₂O = H₄SiO₄ = Si(OH)₄, also probably exists. A few other hydrates of silica have been isolated, but their compositions are not quite definitely established; 2SiO₂·H₂O = H₂Si₂O₃, and 3SiO₂·2H₂O = H₄Si₃O₃, seem to be fairly certain.

Silicates derivable from metasilicic acid O:Si(OH)₂. The typical empirical formule of normal salts of this class are SiO₂M₂O₃, SiO₂MO, 3SiO₂M₂O₃, 4SiO₂R₂O₃MO, and 4SiO₂R₂O₂MO. The atomic ratio of Si to O in these salts is 1:3; this ratio is maintained in the acid salts. Silicates of the forms SiO₂MO and SiO₂M₂O₃ may be represented as basic salts of this class; the atomic ratios of Si to O in these are 1:4 and 1:5. Examples of normal salts of this class are sodium silicate O:Si(ONa)₃, wollastonite O:Si(O₂A₃, and leacite (O:SiO₂)₄Al₂K₂. The basic salts may be regarded as derived from O:Si(OH)₂ by replacing each H by a monovalent basic radicle, such as AlO or ZnOH; for instance, siliceous calamine SiO₂2CnOH,O may be formulated O:Si(OZnOH)₂, and kyanite SiO₂Al₂O₃ is probably O:Si(OAl:O)₂. If only one H is replaced in O:Si(OH)₂ the product will be an acid salt of the metasilicate class; gyrolite, for instance, 3SiO₂2CaO.H₂O may be represented as

O:Si(OH)O.Ca.O.Si.O.Ca.O.(HO)Si:O.

Silicates derivable from hypothetical metadisilicic acid

$$2 \left(\frac{\text{O.Si(OH)}_2}{\text{O.Si.OH.}} - \frac{\text{HoH}}{\text{O}} = \frac{\text{Ho.Si.O.Si.OH.}}{\text{O}} \right)$$
 The

typical empirical formula of normal salts of this class are 2SiO₂M₂O, 2SiO₂MO, 6SiO₂R₂O₃, and 8SiO₂R₂O₂M₂O. The atomic ratio of Si to O in these salts is 2:5; this ratio is maintained in the acid salts. Silicates of the form 2SiO₂2MO.H₂O, wherein the atomic ratio of Si to O is 2:7, may be regarded as basic salts of this class. Petalite 8SiO₂Al₂O₃.Li₂O is probably an example of a normal salt of the metadisilicate class; thus

$$\begin{array}{c} \textbf{0:} \text{Si.0} \\ \overset{\bullet}{\textbf{0}} \\ \textbf{0:} \text{Si.0} \end{array} \hspace{-0.5cm} \text{Al} \begin{array}{c} \textbf{0-} \\ \overset{\bullet}{\textbf{0}} \\ \text{Li0.} \\ \text{Si.0} \end{array}$$

Picrosmine 2SiO₂.2MgO.H₄O may perhaps be a basic salt of this class, (HOMg)O.Si.O.Si.O(MgOH); but it may also be O O

regarded as an acid orthodisilicate (v. infra). One of the soluble glasses, 4SiO_xNa₂O.H₂O, may be written as an acid salt of this class, HO.Si.O.Si.ONa.

Silicates derivable from orthosilicic acid Si(OH),. The typical empirical formulæ of normal salts of this class are SiO.2M.O., SiO.2M.O., SiO.2M.O., and SSiO.2M.O., SiO.3M.O. The atomic ratio of Si to O in these salts is 1:4; this ratio is maintained in the acid salts. Salts of the forms SiO.4MO.2H.O and SiO.2M.O., atomic ratio of Si to O-1:8, may be formulated as basic orthovolume.

silicates. Olivine SiO..2MgO, and sirconits
SiO..ZrO. are likely normal salts of this class;
Mg<0>Si<0>Mg and Si(0,Zr). Xenolite
SSiO..2Al_O, is also a normal orthosilicate;

iO₂.2Al₂O₃, is also a normal orthosilicate; AlO₃:Si.OO₂:Si:O₂O.Si:O₃Al.

Al Al

Andalusite SiO₂.Al₂O₃ is probably partly a basic salt and partly a normal salt of this class; $Si(O_3Al).O.AlO$. Dioptase SiO₂.CuO.H.O may be formulated as an acid salt of the orthosilicate class; $Si(OII)_{x}O_2Cu$.

Silicates derivable from hypothetical orthodisilicic acid

2Si(OH),-H₂O= (HO),Si.O.Si(OH),. The typical empirical formulm of normal salts of this class are 2SiO₂M₂O, 2SiO₂MO, 2SiO₂MO, and 4SiO₂M₂O, 3M₂O. The atomic ratio of Si to O in the normal and acid salts is 2:7. Serpentine 2SiO₂:3MgO is probably a normal salt of this class, (MgO₂)Si.O. Si(O₂Mg). Okenits O.Mg.O

2SiO..CaO.2H.O seems to be an acid salt of this class, HO.Si.O.Si(OH), picrosmine O.Ca

2SiO_x2MgO.H₂O may also be an acid orthodisilicate, MgO_w(HO)Si.O.Si(OH).O_xMg; but it may be formulated as a basic metadlisilicate (v. stopra).

Silicates derivable from hypothetical orthotrisilicic acid. By removing 2H₂O from 3Si(OH), the acid

(HO)₃Si.O.Si.O.Si(OH)₃ would remain. Some (OH)₂

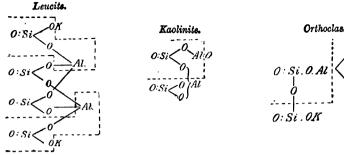

natural silicates may be looked on as salts of this hypothetical acid; mecrschaum, for instance, 3SiO,2MgO.2H₂O, may have the formula MgO₂(HO)Si.O.Si.O.Si(OH).O₂Mg. Groth (l.c.), (OII),

however, thinks it is not necessary to call in a hypothetical trisilicic acid to express the composition of silicates.

Some silicates which do not fit into any of the classes already mentioned may be looked on as derived from more than one of the acids simultaneously. Others may be represented as salts of hypothetical acids formed by climinating water from one or other of the acids that have been mentioned. Orthoclass, 65iO_Al_O_xK_O, may be taken as an example of a silicate derived, according to Groth (l.c.), from two acids, metasilicic and metadisilicic; thus

$$0.Si.< \stackrel{O}{\bigcirc} > Al.O.Si.O.Si.O.K.$$
 Groth urges that

this formula is in keeping with the facts (1) that felspars of the orthoclass class are derived from silicates, such as leucite, which are metasilicates, and (2) that orthoclass readily yields kaolinite 2SiO. Al.O., which may be a basic metadisilicate. Writing leucite as a metasilicate, and kaolinite as a basic metadisilicate, and kaolinite as a basic metadisilicate, it is seen that both contain the group O.SiCO. Al., a group which is represented as present in orthoclass also. Thus

The group common to the three silicates is indicated by the dotted lines. If HHO were removed from orthodisilicic acid the product

Again, $4\text{Si}(OH)_4 - 3HO\Pi = \text{Si}_4O_3(OH)_{10}$ $[(OH)_2\text{Si}.O.\text{Si}.O.\text{Si}.O.\text{Si}(OH)_3]$; if H_2O were $(\ddot{O}H)_2(\ddot{O}H)_2$ removed from this hypothetical orthotetrasilicic acid, there would result Si,O,(OH), O:Si.O.Si.O.Si.O.Si(OH)37; and from this ĊΗ нонононо might be derived the following acids:-[O:Si.O.Si.O.Si.O.Si:0] он онононон он and Si,O,(OH), ононон O:Si.O.Si.O.Si.O.Si:O Ö Si₂O₂(OH)₂

Some of the natural silicates may be represented as derived from one or other of these acids. Acids containing OH yield Cl derivatives wherein OH is replaced by Cl, generally by interaction with PCl. As Cl derivatives of some of the hypothetical silicic acids are known, the existence of these derivatives is an argument in favour of representing certain silicates as salts of acids which have not themselves been isolated. Thus, besides SiCl., which corresponds with orthosilicic acid Si(OH), and SiCl., SH, which is derived from the hypothetical orthothosilicic acid, there exists Si,OCl, corresponding with ortho-disilicic acid Si,O(OH), Si,O,Cl, corresponding with ortho-tetrasilicic acid Si,O,(OH), soli,O,Cl, corresponding with the acid Si,O,(OH), and Si,O,Cl, corresponding with the acid Si,O,(OH), to supra).

Clarke (l.c.), recognising the two main divisions of ortho silicates and meta-silicates, seeks to derive the various members of each class as

far as possible from the typical normal aluminium salts by substituting metals or basic groups, wholly or partially, for Al.

Orthosilicates. Clarke starts with normal Al orthosilicate, 3SiO_x2Al₂O₃=Al₄(SiO₄)₃, which forms the mineral species xenolite; allied to xenolite are fibrolite SiO_xAl₂O₃=Al₂SiO₄, topaz SiO_xAl₂O₅P₂=Al₂SiO₁P₂, muscovite 6SiO_x3Al₂O₃K₂O₂2H₂O = 2Al₃KH₂(SiO₄)₃, paragonite, corresponding with muscovite but containing Na in place of K, and eucryptite 2SiO_xAl₂O₃Li₂O = 2AlLiSiO₄. By trebling the formulæ given for fibrolite and topaz, using the simplest formula given for muscovite and paragonite, and trebling the simplest formula given for eucryptite, Clarke arrives at the following comparable formulæ for the six silicates:—

These silicates are represented as derived from normal Al orthosilicate by substituting either metals, metals and hydrogen, or basic groups, for Al. If such substitution is carried further a series of silicates may be obtained, for some of which Clarke suggests the following formulæ:—

$\begin{array}{l} Dumortierite.\\ \text{O.Si:}O_{3}\text{:}(AlO)_{3}\\ \text{O.Si:}O_{3}\text{:}(AlO)_{2}\\ \text{O.Si:}O_{3}\text{:}Al \end{array}$	$\begin{array}{c} \textit{Grossularite.} \\ \text{Al} \left\{ \begin{array}{c} \text{O.Si:O_s} \\ \text{O.Si:O_s} \end{array} \right\} \\ \text{O.Si:O_s:Al} \end{array}$
$\begin{array}{c} \textbf{Prehnite.} \\ \textbf{O.Si:} \textbf{O.si:} \textbf{O.si:} \textbf{CaH} \\ \textbf{O.Si:} \textbf{O.si:}$	$\begin{array}{c} \textbf{Natrolite.} \\ \textbf{O.Si:O_s:NaH,} \\ \textbf{O.Si:O_s:NaH,} \\ \textbf{O.Si:O_s:Al} \end{array}$

Fibrolite alters by hydration, giving westanite 4SiO, 3ALO, HLO = 2Al, HSi,O, kaolinite 2SiO, Al,O, 2HLO = Al, Si,H,O, and montmorillonite 4SiO, Al,O, 7H,O = 2AlSi,H,O, Clarke suggests the following formulæ for these products of alteration of fibrolite;—

If it is supposed that two groups Al(O.Si:O₃), combine with elimination of one of the O.Sio, groups (= SiO₂+2O), then there remains the

a number of silicates, especially iron and magnesian micas, may be derived. Thus-

$$\begin{array}{c|c} \textbf{Annite.} & \textbf{Sodalite.} \\ \textbf{O.Si:O_3:FeH} & \textbf{Al} \begin{cases} \textbf{O.Si:O_3:FeH} \\ \textbf{O.Si:O_3:FeH} \\ \textbf{O_2:Si:O_2:K_2} \\ \textbf{Al} \begin{cases} \textbf{O.Si:O_3:FeH} \\ \textbf{O.Si:O_3:FeH} \\ \textbf{O.Si:O_3:FeH} \\ \textbf{O.Si:O_3:FeH} \\ \textbf{Nosean.} \\ \end{array} \\ \textbf{Nosean.} \end{array}$$

Noscan. O.Si:Oa:Nas 0.Si:0,:Al Oz:Si:Oz:Nag Al O.Si:O.Al (SO.Na

Clarke (Am. 10, 126) suggests that ultramarine may be analogous to these silicates;

thus,
$$\begin{array}{c}
A1 \\
O.Si:O_3:Na_3\\
O.Si:O_2:Na_3\\
O.Si:O_2:Na_3\\
A1 \\
O.Si:O_3:A1\\
S.Na
\end{array}$$

The metasilicates are considered by Clarke (l.c.) in a way similar to that whereby he has elucidated the orthosilicates. The startingpoint is Al metasilicate, Al₂(SiO₃)₃. This salt is not itself known. The formula may be

Inasmuch as many metasilicates of the form AlM(SiO₃)₂, where M=Li, K, Na, H, may be simply derived from the first, but not from the second, formula given for Al2(SiO3)3, thus O:Si:O,:Al.O.Si:O OM, Clarke thinks that the first

formula may be taken to represent Al₂(SiO₃)₃. Several other metasilicates may be formulated as derived from the Al salt by substituting metals or basic groups for one of the AlSiO, groups; or many metasilicates containing divalent metals may bem ore simply derived from the normal form MuSiO,, by doubling this formula and then replacing one MII in the formula MIIMII(SiOa), by other metals or by basic groups.

The species albite and orthoclase, AlMSi,O, are looked on by Clarke as derived from the

Al salt of the acid H₄Si₂O₈ (-8SiO₂·2H₄O), which acid has probably been isolated, in the same way as many orthosilicates are derived by him from the normal Al salt Al, (SiO,) s. The triclinic felspars are generally thought to consist of mixtures ranging between the limits marked by albite AlNaSi3O8, and anorthite Al2Ca(SiO4)2; if these formulæ are trebled and written thus

Anorthite.

$$\begin{array}{l} \mathbf{A}\mathbf{l} \left\{ \begin{array}{l} \mathbf{O}.\mathbf{Si}:\mathbf{O}_3 = \mathbf{Ca}_2 = \mathbf{O}_3:\mathbf{Si}.\mathbf{O} \\ \mathbf{O}.\mathbf{Si}:\mathbf{O}_2:\mathbf{A}\mathbf{l} & \mathbf{Al}:\mathbf{O}_3:\mathbf{Si}.\mathbf{O} \\ \mathbf{O}.\mathbf{Si}:\mathbf{O}_3:\mathbf{A}\mathbf{l} & \mathbf{Al}:\mathbf{O}_2:\mathbf{Si}.\mathbf{O} \end{array} \right\} \mathbf{A}\mathbf{l} \\ \mathbf{A}\mathbf{l}bite. \end{array}$$

O.Si₃O,:Na₃ O.Si₃O,:Al both silicates repre-O.Si,O,:Al

sented by strictly comparable formulæ. also draws attention to the fact that the four silicates muscovite 6SiO₂.3Al₂O₃.K₂O.H₂O, garnet 3SiO2.Al2O3.3CaO, orthoclase AlKSi3O3, and tourmaline 4SiO2.Al2O3.2M2O3(or 6MO)B2O3, are very frequently associated in granite veins. By halving the formula for muscovite and writing it Al3KH2(SiO4)3, writing the formula for garnet Al2Ca3(SiO4)3, trebling the formula for orthoclase and writing it Al, K, (Si,O,), halving the formula for tourmaline and writing it AlR (BO2)(SiO4)29 where R is a metal or group equivalent to Al. very suggestive relationships are disclosed between the four silicates; thus

$$\begin{array}{lll} \textit{Muscovite.} & \textit{Garnet.} \\ \text{Al} \left\{ \begin{matrix} \text{O.Si:O}_s \text{iKH}_2 \\ \text{O.Si:O}_s \text{iAl} \\ \text{O.Si:O}_s \text{iAl} \end{matrix} \right. & \text{Al} \left\{ \begin{matrix} \text{O.Si:O}_s \\ \text{O.Si:O}_s \\ \text{O.Si:O}_s \text{iAl} \end{matrix} \right. \\ \textit{Tournaline.} & \textit{Orthoclase.} \\ \text{Al} \left\{ \begin{matrix} \text{B:O}_2 \\ \text{O.Si:O}_s \text{iR} \\ \text{O.Si:O}_s \text{iR} \end{matrix} \right. & \text{Al} \left\{ \begin{matrix} \text{O.Si}_s \text{O}_s \text{iA} \\ \text{O.Si}_s \text{O}_s \text{iAl} \\ \text{O.Si}_s \text{O}_s \text{iAl} \end{matrix} \right. \end{array} \right.$$

In Am. S. for November 1889 ([3] 38, 384), and A. C. J. May 1893, Clarke has applied the substitution method, as sketched above, to the mica group of silicates, and in the same journal for March 1892 (Am. S. [3] 43, 190) he has applied the same method to the chlorite group.

The micas all fall within the limits of composition indicated by the two formulæ Al₃Ri₃(SiO₄)₃ and AlR₀'(Si₂O₈)₃. The first formula is derived from Al₄(SiO₄)₃ by substituting Al by one trivalent or three monovalent basic radicles; the esecond formula is derived from the hypothetical salt Al₄(Si₈O₈), by substituting one, two, or three Al atoms by equivalent basic radicles. When F is present it is regarded as forming part of one or other of the monovalent groups Mg.F or Al:F₂. If the ratio of O to Si is greater than 40:Si(SiO₄) the excess of O is looked on as combined with metal to form a basic group, such as Al:O; if the ratio of O to Si is less than 40:Si the group Si,O, is supposed to be present. The micas are all capable of being represented as isomorphous mixtures of various constituents, the compositions of which fall within the limiting formulæ.

The chlorites are treated by Clarke (l.c.) similarly to the micas. In Am. S. [3] 43, 198 he gives the following general formulæ which summarise the composition of the chief micas

and chlorites :-

Normal orthosilicate Al (SiO,) ..

Micas. Muscovite Al₃(SiO₄)₃R₃. Normal Biolite Al₂(SiO₄)₃R₃. Normal Phlogopite Al (SiO) Rg. Clintonite RII: O.: Al(SiO.)R...

Normal orthosilicate Mg, (SiO,)20 Chlorites. Aphrosiderite Mg3(SiO4)2R2. $\begin{cases} \mathbf{Mg}_2(\mathrm{SiO}_4)_2\mathbf{R}_4, \\ \mathbf{Mg}(\mathrm{SiO}_4)_2\mathbf{R}_6. \end{cases}$ **Orthochlorites** Amesite O:Mg,(SiO,)R2.

Preparation of silicates.-Alkali silicates are formed by dissolving moist amorphous SiO, in boiling solutions of alkalis or alkali carbonates. also by fusing SiO2 with alkalis or with alkali salts of acids which volatilise by heat. Many other silicates are obtainable by double decompositions between alkali silicates (which are sol. water) and metallic salt solutions; also by heating various metallic oxides or carbonates

with SiO2.

Some naturally occurring silicates have been prepared by the following methods:-1. Emerald Be, SiO, clivine Mg, SiO, and enstatite MgSiO, by heating SiO, with BeO or MgO mixed with boric acid in a porcelain-oven, till the boric acid volatilised (Ebelmen, A. Ch. [3] 22, 211).—2. Anorthite Al₂Ca(SiO₄)₂, abradorite 3SiO_Al₂O₃,K₂O, and oligoclase 9SiO₂,2Al₂O₃,2K₀O, by strongly heating SiO₂ with K₂CO₃ in boric acid, or by adding CaO to molten boric acid and SiO, at a very high temperature (E., C. R. 32, 710; Fouquet a. Lévy, C. R. 90, 620).—3. Zirconite ZrSiO,, and kyanite (AlO), SiO3, by heating to redness ZrO2 in vapour of H₂SiF_s, or SiO₂ in vapour of AlF_s (Deville a. Caron, A. Ch. [4] 5, 113; Fremy a. Feil, C. R. 85, 1032).—4. Enstatite MgSiO_s, and leucite Al₂K₂(SiO₃)₄, by heating Mg, or Al mixed with KOH, to low redness in H and SiCl₄ vapour (St. Meunier, C. R. 90, 349, 1009).—5. Ortho-clase AlKSi₂O₈, albite AlNaSi₂O₈, petalite AlLi(Si₂O₈)₂, by fusing a mixture of Al₂O₃, SiO₂, and tungstate or vanadate of K, Na, or Li; with and tungstue of vanadate of R, Na, of Li; with excess of Al₂O₂ leucite Al₂K.(SiO₂), is obtained (Hautefeuille, C. R. 90, 378, 541).—6. Orthoclase AlKSi₂O₈, by heating Al₂O₂ and SiO₂, in the ratio Al₂O₂:6SiO₂, with KVO₂ (Hautefeuille a. Perrey, C. R. 107, 786).—7. Phenacite Be₄(SiO₄) mixed with a lithia felspar, quarts, and tridymite, was obtained by heating for fifteen days at 600°-700° a mixture of 4.8 g, 8iO., 1.5 g, BeO, 20 g, LiVO., and 1.5 g, Li₂CO., (H. a. P., C. R. 106, 1800).—8. Crystals of emerald heating a mixture of 12.506 g. SiO₂, 3.58 g. Al₂O₃, 2.64 g. BeO, 6 g. Cr₂O₃, and 92 g. acid Li molybdate (ratio = Li₂O:2½MoO₃); the mixture was placed in a Pt crucible, which was heated in a muffle to low redness for twenty-four hours, when the temperature was raised to 800° and kept thereat for fourteen days. The product was washed with water.

Properties and Reactions of Silicates.—All silicates except those of the alkalis are insol. water; most of them are also insol. dil. acids. For the action of water on certain silicates when the mixtures were rapidly rotated in cylindrical

vessels v. Daubrée (C. R. 64, 839). Many silicates are decomposed by evaporation with HClAq or HNO, Aq, with separation of SiO, xH,O, which is changed to SiO, by heating somewhat above 100°. Some of those silicates which are not thus decomposed are acted on, with separation of SiO₂.xH₂O, by evaporating with 8 parts conc. H₂SO₄ and 3 parts water. Almost all silicates are decomposed by heating with conc. HClAq or H.SO, and a little water in sealed tubes to c. 200°. Heating with conc. HFAq, or in HF gas, decomposes silicates with formation of SiF4; when a silicate is mixed with 3 parts AmF or 5 parts powdered CaF2, and the mixture well moistened with H2SO4, and heated in a Pt dish. all the Si is given off as SiF. Fusion of a finely-powdered silicate with 4-6 parts mixed K2CO, and Na2CO, gives K and Na silicate (which is sol. water), while the metal remains as oxide. Silicates which contain F generally lose HF or silicofluoride when strongly heated; any alkali or alkaline metal, or Fe or Al, which was present in the silicate in combination with F remains as oxide (Rammelsberg, W. 7, 146). Clarke a. Schneider (Am. S. [3] 40, 303, 405, 452) have studied quantitatively the interactions of various natural silicates with HCl gas and also with HClAq; their results make it probable that in the magnesian silicates gaseous HCl attacks only the Mg which is present as the basic monovalent radicle Mg.OH.

The following account of individual silicates does not refer to silicates which occur in rocks. but only to those salts which have been prepared in the laboratory; the chief naturally occurring silicates that have been prepared artificially are mentioned under the heading

artinially are mentioned under the heading Preparation of silicates (supra).

Barium silicates. The normal meta-salt BaSiO₃.xH₂O is formed by ppg. dil. Na₂SiO₃Aq (v. Sodium silicates, infra) by dil. BaCl₂Aq or Ba(NO₃)₂Aq; not quite insol. hot water, easily sol. dil. HClAq; retains water at 100° (Ammon, J. 1862. 138). Lefort (J. Ph. [3] 39, 31) says that BaO.3SiO₂. 3aq (? BaH_Si₂O₈. 2aq) is formed by ppg. a dil. Ba salt solution by a dil. solution by ppg. a dil. Ba salt solution by a dil. solution

of 9SiO,.2Na,O.

Calcium silicates. The compounds 3SiO₂.CaO, 2SiO₂.CaO, 3SiO₂.2CaO, and SiO₂.2CaO, are said to be produced by very strongly heating mixtures of quartz and marble in the proper proportions. By adding CaCl₂Aq to solution of 3SiO₂.K₂O, a gelatinous pp. is obtained which becomes crystalline after a botained which becomes crystainine after a time; dried at 100°, the solid is said to be 3SiO_x.CaO. 2aq (? CaH_xSi_xO_x.aq). The normal mcta-salt CaSiO_x is said to be formed by ppg. Na_xSiO_xAq by dil. CaCl_xAq (v. A., l.c.; L., l.c.). Calcium silicates form the bases of most hydraulic cements (v. Cements in Dictionary of APPLIED CHEMISTRY).

The normal meta-salt Cerium silicate. Ce(SiO₃)₂ is said to be formed by fusing Ce oxychloride with SiO₂ and CaCl₂ or NaCl (Didier, C. R. 101, 882).

Cobalt silicate. The normal ortho- salt Co₂SiO₄ is formed, according to Bourgeois (C. R. 108, 1177), by very strongly heating CoO with

CoCl, and a large excess of SiO₂.

Nickel silicate. Normal ortho-salt Ni₂SiO₄

formed like the Co salt (B., I.c.).

Magnesium silicate. The gelatinous pp. obtained by adding MgCl₂Aq to solution of 8SiO₂.K₂O is said to be 2SiO₂.MgO.2H₂O (? MgH₂(SiO₃)₂, aq acid meta-salt) (Heldt, J. pr. 94, 129, 157). The normal meta-salt MgSiO₂.xH₂O is obtained, according to Ammon (l.c.), by ppg. Na₂SiO₂Aq by dil. MgCl₂Aq. Potassium silicates. The normal meta-salt

K₂SiO₂ is prepared by fusing 1 part SiO₂ with 2½ parts dry K₂CO₃. If this product is dissolved in a little water, and alcohol is added, a gelatinous pp. is formed, which, if slightly washed and squeezed, is said to be 4SiO₂-K₂O; but Fremy (J. 1856. 353) gives the composition 9SiO₂-2K₂O aq to this pp., and this is confirmed

by Lefort (J. 1861. 205).

The name potash water-glass is given to the mixture of K silicates obtained by fusing together quartz and pearlash in a proportion about equal to 4SiO_xK_xO. Water-glass is a clear transparent solid, like glass; it is completely sol. hot water; a conc. solution, with c.28 p.c. silicate, is syrupy, somewhat turbid, and has S.G. 1.25. The solution is decomposed by acids, even by CO_x with separation of SiO_xxH_xO; alkaline carbonates and chlorides, especially AmCl, ppt. SiO_xxH_xO; BaO, SrO, CaO, Al.O_x, and PbO decompose the solution, forming a double silicate with the whole of the silica and a portion of the K. The solution yields pps. with solutions of most of the salts of earth metals and heavy metals. Water-glass is also formed by boiling SiO_x with KOHAq under pressure. Sodium silicates. The normal meta-salt

Na,SiO, is prepared by fusing 1 part SiO, with 13 parts dry Na₂CO₃. The salt is obtained with 8H,O, in monoclinic crystals, by dissolving SiO, in an equivalent quantity of NaOH in solution, decanting, evaporating, as much as possible out of contact with air, till Na,CO, begins to settle out, cooling to -22°, stirring till the whole solidifies, straining from motherliquor, dissolving in a little water, and allowing to stand (Ammon, J. 1862. 138; cf. Ordway, Am. S. [2] 40, 186). By adding freshly ppd. AlO₃H₄ to a boiling solution of Na₂SiO₃ and NaOII, the double salt Na₂SiO₃Al₄(SiO₄)₃ is obtained; and the salt Na, SiO, Al, (SiO,) is ppd. by adding Na, SiO, Aq to a hot solution of alum (A., l.c.). Mixtures of Na silicates are known as soda water-glass (cf. supra, Potash water-glass). For effect of time on composition of solutions of Na silicates v. Kohlrausch (Z. P. C. 12, 773).

Strontium silicate. The normal meta-salt SrSiO₂ is said to be formed by adding Na,SiO₃Aq to dil. SrCl.Aq (Ammon, l.c.).

Thorium silicates. The normal ortho-salt

Thorium silicates. The normal ortho-salt ThSiO₄ and the normal meta-salt Th(SiO₃), are formed, according to Troost a. Ouvrard (O. R. 105, 220), by fusing ThO₂ with SiO₂ and CaCl₂ and treating with dil. HClAq. ThSiO₄ is not isomorphous with ZrSiO₄ (T. a. O., l.c.).

Zine silicates. The normal meta-salt ZnSiO₈

Zinc silicates. The normal meta-salt ZnSiO₂ is obtained in rhombic crystals by ppg. ZnSO₄Aq by Na₂SiO₂Aq, and strongly heating the dried powith boric acid for several days (H. Traube, B.

26, 2735).

A systematic arrangement of the naturally occurring silicates will be found in Groth's Tabell. Uebersichte, pp. 108-151 [Brd ed.].

M. M. P. M.

SILICIC ACIDS v. SILICA, HYDRATES OF, p. 447).

BILICIDES. Binary compounds of Si with metals. These compounds are formed (1) by heating amorphous Si with metallic chlorides in presence of such a reducer as Na; (2) by heating K₂SiF₆ with metals; (3) by electrolysing a mixture of an alkali fluoride with a metallic oxide; (4) by heating metals with Si (v. Aluminum, Cerbum, Copper, Iron, Magnesium, Manganese, Nickel, Platinum, silicides of). M. M. P. M.

SILICO-BORATES. Certain minerals consist of compounds of silicates and borates; the name silico-borate is sometimes applied to such O:Si.O.

compounds. Datholite O.Si.O Ca.CaB₂O₄, aq,

and botryolite, the same formula with 2aq, are examples of borosilicates. Tourmalines Al(BO₂)(SiO₄)₂RI₅ are also silico-borates (R¹ may be replaced by its equivalent of R¹¹).

M. M. P. M. SILICO-BROMOFORM SiHBr₃. (Silicon hygen bromide. Tribromo-silico-methane.) drogen bromide. Obtained, not quite pure, by Baff and Wöhler (A. 104, 99) by leading HBr gas over heated Si, distilling the product, shaking with Hg, and distilling again. Gattermann (B. 22, 193) obtained pure SiHBr, as follows. Crude Mg silicide, prepared as described under Silicon, Preparation, No. 1 (p. 456), is freed from MgO by powdering, adding little by little to HClAq (1:2), shaking with this acid for some hours, washing till the wash-water is neutral, and drying thoroughly. The Si thus obtained is heated in a tube in a stream of HBr, the tube being connected with a well-cooled receiver; the details and precautions described under Silicon TETRICIDENTIE, Preparation, No. 2 (p. 458) must be observed. The HBr required may be made by the action of H.SO, Aq on KBr; G. used a cold mixture of 45 c.c. conc. H2SO, and 15 c.c. water, and let this drop on to 75 g. KBr; he dried the gas by H₂SO₄. The liquid is distilled, and then fractionated till a portion boils at 115°-117°; most of the remainder boils at c. 153° and is SiBr. A colourless liquid, boiling 115°-117°; S.G. 2.7 at ordinary temperature (G., l.c.). Fumes much in air, and takes fire, probably because the heat produced in the decomposition of a portion by the moisture of the air suffices to start rapid oxidation (G., l.c.). Ice-cold water forms silico-formic anhydride (4. v., p. 455). Combines with PH3, when compressed, to form a solid, unstable compound (Besson, C. R. 112, 530). M. M. P. M.

SILICO-CHLOROFORM SHCI, (Silicon hydrogen chloride, Trichloro-silico-methane.)
Mol. w. 135-41. V.D. 67.

Formation.—1. Dry HCl gas is passed over Si heated below redness; the product is condensed in a flask in a freezing mixture and fractionated (Friedel a. J. adenburg, A. 143, 118; cf. Buff a. Wöhler, A. 104, 94).—2. Dry HCl gas is passed over siliceous pig-iron containing 15 p.c. Si (Warren, C. N. 60, 158).

Preparation.—Si, prepared by reducing sand by Mg (v. Sillicon, Preparation, No. 1, p. 456) and removing MgO as described under Sillico-BROMOFORM (supra), is carefully heated in a stream of dry HCl gas in a tube connected with a receiver surrounded by a very good freezing mixture. The directions given for preparing SiCl, must be carefully followed (v. Silicon tetrachloride, Preparation, No. 2). [Gattermann recommends to make the HCl in a Kipp's generator, using conc. H₂SO₄ and fused NH₄Cl.]
The liquid in the receiver is fractionated from a flask with a side tube 75 cms. long; if this is done, no condenser is required; the flask must be warmed by water at 90°, if a naked flame is used explosions of part of the SiHCl, may result (Gattermann, B. 22, 190).

Properties and Reactions .- A colourless, mobile liquid, with a very disagreeable smell; boils at 35°-39° (F. a. L., l.c.). Non-conductor

of electricity.

The vapour takes fire very easily in air, e.g. by bringing a hot glass rod to the mouth of a vessel in which a little SiHCl, has been shaken. Mixture of the vapour with air is explosive. Decomposed to Si and HCl by passing through a narrow tube heated to redness. Water at 0° forms Si₂O₃H₂ (v. Silicoformic anhydride, p. 455) and HCr; at the ordinary temperature SiO,xH,O, HClAq, and H are produced. Chlorine reacts at ordinary temperatures, forming SiCl, and HCl; bromine reacts similarly at 100°. Alcohol produces SiH(OEt), (v. SILICON TETRA-HYDRIDE, Preparation, No. 1, p. 460). Combines with phosphorus hydride, under pressure, to form a solid unstable body (Besson, C. R. 112, 530).

M. M. P. M. 530).

SILICO-ETHANE, PENTA-BROMO- DERI-VATIVE OF, Si.HBr. (Disilicon hydrogen pentabromide. Pentabromo-silico-ethane.) In pentabromide. Pentabromo-silico-cihane.) In making SiBr, by passing SiH, into Br, Mahn (J. Z. 5, 163) obtained a solid in the form of white needles, melting at 89° and boiling (out of contact with air) at 230°, and giving numbers on analysis agreeing with the formula Si. HBr. Takes fire when heated in air. M. M. P. M.

SILICO-FLUORHYDRIC ACID H.SiF,Aq. (Hydrofluosilicic acid.) Known only in aqueous solution.

Preparation.—SiF₄, prepared by the interaction of CaF₂, SiO₂, and H₂SO₄ (v. Silicon TETRAFLUORIDE, p. 459), is passed into water, the exit tube dipping beneath a little Hg in the bottom of the vessel which contains the water; the vessel is shaken frequently to break up the gelatinous silica which forms in the water; when the liquid becomes thickish from separated silica, it is filtered through linen, the silica is pressed, and more SiF, is passed into the filtrate, as before.

(1) SiF₄ + 3H₂O + Aq = SiO_{...}H₂O + 4HFAq; (2) 4HFAq + 2SiF₄ = 2H₂SiF₆Aq. The solution of H2SiF6 may be evaporated in a Pt vessel till

it contains c. 34 p.c. of the acid.

To prepare the acid solution on a large scale, Tessié du Mothay recommends to fuse a mixture of fluorspar, silica, and charcoal in an oven, and to lead the gas that is given off through condensers containing water; c. 68 p.c. of the F in the fluorspar is thus obtained as H₂SiF_s (C. C. 1868. 432).

Properties and Reactions. - H2SiF4Aq is a strongly-acid liquid, smelling like HClAq, and burning the skin. If kept in glass vessels it gradually withdraws alkali, lime, and iron

oxide (H. Rose, P. 80, 408). Truchot (C. R. 98, 821) gives H.F. [SiF',2HFAq] = 17,000 (cf. Sabatier, A. Ch. [5] 22, 91). Thomsen gives [SiO'Aq,0HFAq] = 32,800; and the heat of neutralisation as [H2SiF6Aq,2NaOHAq] = 26,600 (Th. 1, 236). The following table is given by Stolba (J. pr. 90, 193):-

S.G. P.c. S.G. H_SiF_Aq H_SiF_ H_SiF_Aq	P.o. H.Sif.
1.0040 0.5 1.1559	18
1.0080 1 1.1653	19

1.1466 17	

The S.G. for any percentage of H_2SiF_6 , when n = number of half-per-cents., is given by the formula; S.G. = $1 + n \cdot 004 + \frac{n(n-3) + 2}{n(n-3) + 2}$ 100000

By passing SiF, into fairly conc. HFAq until the liquid is saturated, hard, colourless, very hygroscopic crystals of the hydrate H.SiF. 2H.O separate; the crystals melt at 19°, and decompose at a higher temperature (Kessler, C. R. 90,

H.SiF.Aq acts as a dibasic acid (the heat of neutralisation confirms this), giving salts M12SiF6 and MuSiFa; with excess of a strongly basic metallic oxide it forms metallic fluoride and $\begin{array}{l} \mathrm{SiO}_{2}\mathrm{\cdot H}_{2}\mathrm{O} - \mathrm{thus} \\ \mathrm{\cdot H}_{2}\mathrm{SiF}_{0}\mathrm{Aq} + 3\mathrm{K}_{2}\mathrm{O} - \mathrm{SiO}_{2}\mathrm{\cdot H}_{2}\mathrm{O} + 6\mathrm{KFAq}. \end{array}$

H.SiF. Aq is decomposed by conc. H.SO., also by HCl gas, with formation of SiF. and withdrawal of water. Boric acid separates SiO2.xH2O and forms fluoboric acid (q.v., vol. i. М. М. Р. М. p. 530)

Salts of H₂SiF₆ (v. preceding article). These salts are formed by dissolving various metalse.g. Fe or Zn-in H.SiF.Aq, or by neutralising the acid solution by the proper quantities of basic oxides or hydroxides; if excess of a strongly basic oxide is added to H₂SiF₆Aq, SiO₂·H₂O is separated and a fluoride is formed. Most of the silicofluorides are sol. water; the salts of Ba, K, Na, Ce, and a few elements allied thereto, are only slightly sol. water and insol. alcohol. Aqueous solutions of silicofluorides have an acid reaction to litmus. Silicofluorides are generally decomposed by heat, giving off SiF, and leaving fluorides; heated with AmCl, metallic chlorides remain (Stolba, J. pr. 101, 157). Some silicofluorides are de composed by heating strongly with Fe or K, forming fluoride and Si. Conc. H₂SO₄ evolves H₂SiF₄, when heated HF is given off; conc. HClAq and HNO₃Aq react similarly, but more slowly and less completely; but H.SiF.Aq

SILICON. 458

partially decomposes most chlorides and nitrates in solution. Truchot (C. R. 98, 821, 1330) gives the heats of formation of alkali silicofluorides. M. M. P. M.

By the action of SILICO-FORMIC ACID. water on (?) Sil, Friedel a. Ladenburg (A. 203, 247) obtained a white solid that gave off H when treated with KOHAq; the amount of H obtained agreed fairly well with the formula SiH₂O₂. If this formula is correct, the compound is probably the Si analogue of formic M. M. P. M.

H,Si,O, SILICO-FORMIC ANHYDRIDE HŞi:O

This body represents among Si com-HŠi:O. pounds the hypothetical formic anhydride ÎIÇ:0

Prepared by slowly distilling SiHCl, HĊ:O. into water kept at 0°, filtering quickly the solid that separates, washing with ice-cold water, drying in vacuo over H.SO, and then at 150° the SiHCl, is distilled from a small flask and the distillation-tube is fused on to an inverted funnel which dips beneath the water; 2SiHCl₃+3H₂O = 6HCl+Si₂H₂O₃ (Friedel a. Ladenburg, A. 143, 118; cf. Buff a. Wöhler, A. 104, 101; also Gattermann, B. 12, 186). A white, amorphous, light powder; floats in water, sinks in ether; sl. sol. water. Does not decompose at 300°, but at higher temperatures it glows and gives off H which takes fire explosively; burns when heated in O, emitting a brilliant light; burns when heated in a covered crucible, with formation of some amorphous Si. Heated in tube, SiH, is given off and a thin layer of amorphous Si remains. Not acted on by acids, except HFAq which dissolves it with rapid evolution of H. Alkali and alkali carbonate solutions, including NH3Aq, dissolve this compound, giving off H, and forming alkali silicates. A freshly-prepared aqueous solution of H2Si2O, acts as an energetic reducer; AuClaAq is reduced to Au; Pd salts probably to Pd mixed with Pd silicate; SeO2Aq, SO2Aq, TeO2Aq, and HgCl2Aq are reduced to Se, S, Te, and HgCl. CroaAq, indigo solution, and salts of Pt and Ir are not reduced.

The substance obtained by Wöhler, by the action of light and water on the body he named silicone (v. Silicon, compounds of, with hydrogen AND OXYGEN, p. 459), and called by him leukon (A. 127, 268), and also the substance called by (A. 121, 200). The solid control of the solid contr

SILICO-IODOFORM SiHI₃. (Silicon hydrogen iodide. Tri-iodo-silico-methane.) Formula probably molecular, from analogy of SiHCl, Obtained in small quantities by the interaction of HI and crystalline Si at red heat (Buff a. Wöhler, A. 104, 99); better prepared by diluting the HI vapour with H; the product, which is a mixture of SiI, and SiHI, is repeatedly fractionated; SiI, boils at 290°, SiHI, at c. 200°. A mixture of SiI, and SiHI, is also obtained by heating SiH, with I (Mahn, J. 1869. 248). colourless, refractive liquid; S.G. 3:362 at 0°, 8:314 at 20°; boils at c. 200°. Water produces Si₂H₂O₂ (Friedel, A. 149, 96) (v. Silico-formio M. M. P. M. ANHADRIDE, supra).

SILICO-MOLYBDATES. Compounds con-

taining SiO₂, MoO₃, and basic radicles; v. Molyberts, vol. iii, p. 427.

SILICON. Si. (Silicium.) At.w. 28·3; mol.w. unknown.

H.F. [Si, O'] = 219,240 amorphous Si; 211,120 crystalline Si (Troost a. Haute-feuille, C. R. 70, 252). C.E. (linear at 40°) 00000763 (Fizeau, C. R. 68, 1125). For other properties v. Properties, p. 456.

Historical.—The existence of aspecial earth in rocks that could be melted to glass-like substances was indicated by Pott in 1746. Scheele (Opuscula, 2, 67) and Bergmann (Opuscula, 26) showed that this earth could not be changed into lime or alumina; Smithson in 1811 found that the earth acted like an acid; Berzelius, in 1823, isolated the element of this earth, and in 1854 Deville obtained the same element in crystalline form. The new element was shown to resemble carbon by the researches of Buff and Wöhler and of Friedel and Ladenburg. The name silicon was given from acidum silicum or silex.

Occurrence.—Si is not found uncombined; compounds of Si are very widely distributed in vast quantities; next to oxygen, Si (in combination) is the most widely distributed element. Silicates occur in very many rocks and soils and in plant-ashes; SiO2 is found in many mineral springs and in sea-water (Forchhammer, Pr. E. 2, 303; Bunsen, A. 62, 7, 25), and in small quantities in various animal organisms (von Gorup-Besanez, A. 61, 46; Henneberg, A. 61, 261). Si is found in pig-iron; it is generally supposed to exist therein as crystallised Si, but the experiments of Jordan a. Turner (C. J. 49, 215) make it probable that the Si is combined with Fe as a silicide.

Formation. - Amorphous silicon. - 1. By passing the vapour of SiCl, over heated K, removing excess of SiCl, by a current of dry air, and washing out KCl with water (Berzelius, Lehrb. (1st ed.) 3, 327).—2. By passing vapour of H,SiF, over heated K, washing with water, heating the residue in a covered crucible (to remove H and C), washing with HFAq (to remove SiO₂) and then with water (B., l.c.).—3. By heating a mixture of K₂SiF₄ and K, and washing with water (B., l.c.); Wöhler (A. 104, 107) heats a mixture of Na, SiF, with NaCl and Na.-4. By heating Mg in SiF, vapour (Warren, C. N. 58, 215).-5. By reducing SiO₂ by heating with Mg (v. Preparation, No. 1) .- 6. By elec trolysing a fused silicate in a carbon crucible, with Pt as the positive, and gas-carbon as the negative, electrode (Hampe, Chem. Zeitung, 12, 841). Crystalline silicon .- 7. By heating a mixture of K. SiF., Na, and Zn (v. Preparation, No. 2).—8. By reducing K₂SiF₆ or a silicate by Al (v. Preparation, No. 3).—9. By passing H and SiCl₄ vapour over Zn heated to reduces in a porcelain tube (Beketoff, Bl. 1, 22) .-- 10. By heating a mixture of SiO₂, K₂CO₃, Iceland spar, and Na (Deville, A. Ch. [3] 49, 62).—11. By passing vapour of SiF₄ or SiCl₄ over Si heated to redness (Troost a. Hautefeuille, C. R. 73, 443).-12. By passing vapour of SiCl, over heated Na, or Al, and heating the product (Si with excess of Na or Al) in a carbon crucible (Deville, A. Ch. [8] 49, 62).-13. A piece of siliceous pig-iron is con nected with the positive pole of a battery and

SILICON. 456

immersed in dilute H2SO4Aq, in which a Pt plate connected with the negative pole of the battery is also placed; after some hours the iron has dissolved: the mixture of graphite, amorphous Si and SiO, which remains is heated to full redness for some time with Zn and the fused mass is treated with dilute HClAq (Warren, C. N. 57, 54).

Preparation. - Amorphous silicon. 1. An intimate mixture of 10 g. Mg powder and 40 g. thoroughly dry sand is placed in a testtube, of fairly thick glass, c. 2-3 cms. diameter and c. 15 cms. long; the tube is heated throughout by a large flame, and then the lower part is very strongly heated, when reduction quickly occurs. If the tube is gradually moved downwards so that one part is strongly heated after another, the whole of the SiO2 is reduced in a few minutes. The contents of the tube are shaken out, pulverised, and treated with HClAq (1:2), the solid being added to the acid in small successive quantities (to prevent explosion from evolution of SiH, (Gattermann, B. 22, 186). Crystalline silicon .- 2. A mixture of 15 parts dry K2SiF4, 20 parts dry granulated Zn, and 4 parts dry Na in small pieces is placed in a clay crucible, which is covered and heated to redness; when the reduction of the K2SiF6 is effected (there is a visible, but not violent, reaction) the temperature is raised till the mass melts, care being taken not to heat to the b.p. of zinc, else considerable loss will occur. The crucible is broken when cold, the regulus is heated to the m.p. of zinc, the molten zinc is poured off, and SiO2, Zn, &c., are removed by treatment, in succession, with conc. HClAq, conc. boiling HNO,Aq, and HFAq. The Si, mixed with a little K,SiF, thus obtained is placed in a crucible and covered with a layer of powdered glass; the grucible is set inside another, and heated to the m.p. of pig-iron (c. 1100°). When all is melted the crucible is allowed to cool to dull redness and is then plunged into water; the regulus is separated from the slag, and is treated with HFAq and then washed with water (Caron, A. Ch. [3] 63, 26; Deville a. C., A. Ch. [3] 67, 485).—3. A mixture of 1 part Al with 20-40 parts thoroughly dry K.SiF. or Na.SiF. is heated to c. 950° in a Hessian crucible, and the contents are kept molten for c. a quarter of an hour; the crucible is broken when cold, the regulus is separated, crushed, heated with conc. HClAq as long as H is given off, then with HFAq, and washed with water and dried (Wöhler, A. 97, 261). Or, a mixture of 10 parts powdered cryolite and 5 parts K2SiO3 or powdered glass is divided into two equal parts; one part is placed in a Hessian crucible, 1 part Al is added, the rest of the mixture is placed over this, and the whole is heated to redness for half an hour. The regulus is treated with conc. HClAq, HNO, Aq, &c., as directed above.

Properties. - Si exists as a brown amorphous powder, and also as greyish-black, very lustrous.

octahedral crystals.

Amorphous silicon is a lustrous, brown powder, which adheres to the fingers or to glass tenaciously. The S.G. has not been determined, but the powder is heavier than oil of vitriol; it is a non-conductor of electricity; burns when

heated in air or O, but the SiO, formed soon stops the process; dissolves in cold HFAq, forming SiF, and H; also dissolves in warm alkali solutions; is oxidised with incandescence when thrown into molten nitre; combines with S when warmed therewith. After being strongly heated in a covered Pt crucible, and the SiO2 formed has been removed by HFAq, amorphous Si is a dark chocolate-brown powder, which is not burnt by heating in air or O, is insol. HFAq and boiling alkali solutions, does not combine with S, and is not acted on by molten

KNO, or KClO,

Crystalline silicon is obtained in leaflets The leaflets are opaque, very or needles. lustrous, metal-like, greyish black, resembling graphite; they consist of regular octahedra. The needles are also octahedral. Crystalline Si has S.G. 249 at 10° (Wöhler, J. 9, 437); 2 194 to 2 197 (Winkler, J. 17, 208). Scratches glass, but not topaz. According to Deville (C. R. 39, 321) crystalline Si 'conducts electricity like graphite.' M.P. between those of pig-iron and steel, i.e. between c. 1100° and c. 1300°. Crystalline Si is not changed when heated, even to whiteness, in O; it is unacted on by HFAq; dissolves in warm alkali solutions; combines with S vapour. When heated in the electric are crystalline Si melts and then boils, and the ends of the electrodes become covered with crystals of SiC (Moissan, C. R. 117, 423).

For the lines in the emission spectrum of

Si v. B. A. 1884. 441.

Deville (A. Ch. [3] 49, 70) thought that a graphite-like form of Si existed different from the ordinary crystalline (or diamond-like) form; but Miller (P. M. [3] 31, 397) showed that both the leaflets and the needles consisted of octahedra. Kopp (A. Suppl. 5, 72) found differences between the specific heats of crystalline Si and the graphite-like form prepared by the interaction of K.SiF. and Al, and these differences were confirmed by Winkler (J. pr. 91,

Warren (C. N. 63, 46) thought he had obtained a crystalline form of Si (oblique octahedra) different from the ordinary by the action of impure Al on K,SiF, at a very high temperature; he described the crystals as very perfect, and sometimes half-an-inch across the

Specific heat of silicon. Kopp, Regnault, and others obtained values for the S.H. of Si varying from '138 to '173 at c. 30°-100°. In 1875 Weber (P. M. [4] 49, 161, 276) showed that S.H. of crystallised Si increased rapidly from -40° to c. 200°, and attained an almost constant value at the latter temperature. Weber's results gave the following values for S.H. of crystallised Si:-

3.H.

١

The atomic weight of Si has been determined (1) by finding the ratio of Si to SiO, formed therefrom (Berzelius, P. 1, 226 [1824]); (2) by converting BaSiF, into BaSO, (B., P. 8, 20 [1828]); (8) by ppg. CI in SiCl, by Ag (Pelouze, C. K. 20, 1047 [1846]; Dumas, A. Ch. [3] 55, 183 [1859]); (4) by converting SiCl, into AgCl (Schiel, A. 120, 94 [1861]); (5) by decomposing SiBr, by water and determining SiO₂ produced (Thorpe a. Young, C. J. 51, 576 [1887]); (6) by finding V.D. of SiH, SiCl, SiBr, SiF, &c.; (7) by determining S.H. of Si. The atom of Si is tetravalent in the gaseous molecules SiH, SiCl, SiBr, SiF, SiHCl, &c. The molecular weight of Si is unknown.

Si is closely related to C, and less closely to Ti, Ge, Zr, Sn, Ce, Pb, and Th (v. Carbon Group

OF ELEMENTS, vol. i. p. 682).

Reactions and Combinations.—I. Amorphous silicon which has not been heated .- 1. Heated in air or oxygen burns to SiO2, which coats the Si, so that the process soon stops. -2. Heated with sulphur forms SiS, (Berzelius).-3. In molten nitre forms potassium silicate, with incandescence.-4. Dissolves in cold solution of fluorhydric acid to form SiF, and H.-5. Dissolves in conc. alkali solutions on warming, forming H₂SiO₃Aq (or Na₂SiO₃Aq) and H. For differences between amorphous silicon before and after heating, v. Properties of amorphous silicon, p. 456. II. Crystalline silicon.—6. Is not acted on by oxygen, nor by fluorhydric acid.—7. Heated in dry chlorine forms SiCl,; in bromine vapour forms SiBr,; in a mixture of iodine vapour and CO, forms SiI,; takes fire in fluorine, forming SiF, (Moissan, C. R. 103, 256).—8. Heated with sulphur vapour forms SiS2-9. Strongly heated in nitrogen forms Si₃N₄.—10. Heated to c. 800° in a mixture of oxygen and chlorine, Si,OCl, is formed (Troost a. Hautefeuille, Bl. [2] 35, 360). 11. Dissolves slowly in warm alkali solutions of medium concentration, giving off II.—12. Burns when heated with alkali carbonates, separating C, and giving off CO.—13. SiS₂ is produced (according to Sabatier, Bl. [2] 38, 153) by heating to bright redness in hydrogen sulphide.—
14. Schutzenberger (C. R. 114, 1089) obtained a mixture of Si₃N₄ and a carbide (to which he gives the formula SiC) by heating to bright redness, in a carbon crucible placed inside another crucible packed with lamp-black, a mixture of 1 part Si and 2 parts SiO2.—The following reactions apply generally to silicon .- 15. Heated in hydrogen chloride SiHCl3 is formed; in hydrogen iodide mixed with H, SiHI, is produced; and SiHBr, is obtained by heating in hydrogen bromide.—16. Heated with silicon tetrachloride, Si₂Ol₂ (and ?SiOl₂) is formed.—17. Oxidised by hydrogen iodide solution (o. Ditte, Bl. [2] 13, 322).—18. With molten caustic soda or potash, H is given off and a silicate formed; similar but slower reactions occur with baryta and lime (v. Berzelius, A. 49, 247) .-19. Heated with several metallic oxides, such as PbO or Ag₂O, reduction occurs, generally with formation of a silicide. If a mixture of powdered Si, Al, and PbO is heated, a violent explosion occurs.—20. According to Colson (Bl. [2] 88, 56), Si₂C₂O is formed by heating Si in carbon dioxide; SiS, SiSO, and Si,C,S are formed by heating Si to white heat in carbon disulphide SiCO, is formed by heating with bensene; and Si,C,O, is produced when Si is heated to whiteness in a carbon crucible.

Silicon, amidonitride of. By the interaction of NH₂ and SiCl, or SiF, Harris (C. C. 1889 [ii.] 283) obtained a snow-white powder, to which he gave the formula Si.NH₂.N.

Silicon, carbide of. According to Schutzen-berger (C. R. 114, 1089), a compound of Si and C, having the composition of SiC, is formed along with a little Si₂N₄, by placing a mixture of 1 part crystallised Si and 2 parts SiO₂ in a covered gas-carbon crucible, imbedding this in lamp-black in a larger crucible, and this again in more lamp-black in another larger crucible, and heating to bright redness for some hours: boiling with moderately conc. HFAq dissolves SiO, and Si, N, and leaves the SiC. Heated to low redness in chlorine, SiC is said to give SiCl. and C. Moissan (C. R. 117, 425) obtained colourless crystals of SiC by fusing C and Si in an electric furnace. The crystals are very hard, act strongly on polarised light, S.G. 3.12; they are not acted on by O or S vapour at 1000°; Cl begins to react at c. 600° and the action is complete at 1200°; the crystals are not acted on by boiling HClAq, HNO3, H2SO4, aqua regia, or a mixture of HNO, and HFAq, nor by fused KNO, or KClO,; molten KOH gradually forms K₂CO₃ and K silicate.

Silicon, bromides of. Two bromides of Si

are known, Si₂Br, and SiBr,

DISTLEON HEXABRONIDE Si₂Br_s. (Silicon tribromide SiBr_s.) Formula probably molecular from analogy of Si₂Cl_s. A colourless liquid, boiling at c. 240°. Formed by adding the proper quantity of Br to Si₂I_s in CS_s, pouring off from I, purifying by shaking with Hg, filtering in dry air, and fractionating (Friedel a. Ladenburg. 4. 203, 254).

SILICON TETRABROMIDE SiBr. Mol. w. pro-

bably 347.3.

Preparation.—Amorphous Si, prepared as described under Sillon, Preparation, No. 1 (p. 456), after being partially purified from SiO₂ by HClAq, washing, and drying, is heated in a glass tube, while Br vapour is passed over it; the tube passes into a small flask, which is surrounded by cold water. A mixture of SiBr, and Br collects in the flask; this is fractionated, and the last traces of Br are removed by shaking with Hg and distilling (Gattermann, B. 22, 186). SiBr, may also be prepared by heating a mixture of SiO₂ and C (cf. Sillon Tethachloride, p. 458) in Br, shaking with Hg, and fractionating (Serullas, P. 24, 341; modified by Reynolds, C. J. 51, 500).

Properties and Reactions.—A colourless liquid, having a disagreeable odour, and fuming much in air. S.G. 2.8128 at 0°. B.p. 153.4° at 762.5 mm. (Piorre, A. Ch. [3] 20, 26; Freyer a. Meyer, Zeit. für anorgan. Chemie, 2, 1); 148° to 150° (Sorullas, Lc.). Solidifies at c. -12°. (F. a. L., Lc.). Decomposed by water to HBrAq and SiO₂; shaken with conc. sulphuric actd, slowly changes to Br and SiO₂. Heated to 250° with lead oxide gives PbBr, and Pb silicate (Friedel a. Ladenburg, A. 147, 362). Ammonia probably forms SiBr, NH₂ (Persoz, A. Ch. [2] 44, 315). Phosphorus hydride forms a white amorphous compound, by repeated compression with SiBr, the pressure being maintained for some hours (Besson, C. R. 110, 240).

For the compounds SiBraH and SiBraH v.

SILICOBROMOFORM, and SILICO-ETHANE, PENTA-BBOMO- DERIVATIVE OF, pp. 453, 454.
Silicon, bromochlorides of. Three compounds

of Si with Br and Cl have been isolated. The V.D. of SiBr, Cl, and also that of SiBrCl, has been determined; the formulæ of all are pro-

bably molecular.

SILICON BROMO-TRICHLORIDE SiBrCl. Mol. w. 214.16. A colourless liquid, boiling at c. 80°, fuming in air, and decomposed by water. 80°, tuming in air, and decomposed by water. Prepared by heating Br and SiHCl₃ at 100°; SiHCl₃+Br₂=SiBrCl₃+HBr (Friedel a. Ladenburg, A. 145, 187). Also by the interaction of Br and SiCl₃SH (? SiCl₃SH+3Br=SiBrCl₃+SBr+HBr) (F. a. L., l.c. p. 179). V.D. 104°7 at c. 130° (F. a. L., l.c.). Reacts with NH to form an emerglous compound. with NH, to form an amorphous compound, 2SiBrCl₂.11NH₂, easily decomposed by water (Besson, C. R. 112, 788).

SILICON DIBROMO-DICHLORIDE SiBr.Cl. A colourless liquid, boiling at 103°-105°, and not solidifying at -60° . Prepared by heating SiHCl, and Br above 100° (F. a. L., Lc.). Also by passing the vapour of HBr and SiCl, through a red-hot porcelain tube (Besson, l.c.). Combines with NH₃ to form SiBr₂Cl₂.5NH₃, decom-

posed by water.

SILICON TRIBROMO-CHLORIDE SiBr.Cl. Mol. w. 302.92. A colourless liquid, fuming in air, boiling at 140° – 141° , not solidifying at -40° ; S.G. $2\cdot432$. V.D. $150\cdot5$ at c. 185° (Reynolds, C. J. 51, 590). Obtained, along with SBr., by passing Br vapour over a mixture of SiO, and C heated in a wind-furnace, passing dry H through the warm product, shaking with Hg, and fractionating (R., l.c.). Besson (C. R. 112, 788) seems to have obtained the same compound, along with SiBr,Cl, by passing the vapours of HBr and SiCl, through a redhot porcelain tube. B. gives the b.p. 126°-128°, and m.p. -39°; he says a compound SiBr.Cl.11NH, is formed by interaction with

NH...
Silicon, brome-iodides of, v. Silicon iodo-

BROMIDES, p. 461.

Silicon, chlorides of. Two chlorides of Si have been isolated with certainty, Si2Cla and SiCl.; these formulæ are molecular. There are indications of the existence of another chloride, SiCl.

SILICON HEXACHLORIDE Si2Cls. (Silicon tri-

chloride SiCl₂.) Mol. w. 268-22.

Preparation.—1. By heating HgCl₂ with Si₂I_e, fractionating, and distilling the portion boiling at 146°-148° from HgCl₂ (Friedel a. Ladenburg, A. 203, 253).-2. Vapour of SiCl, is passed over Si kept molten in a porcelain tube (3SiCl₄ + Si = 2Si₂Cl₃); the product is rapidly cooled, and fractionated from SiCl₄, Si oxychlorides (and ? SiCl2) (Troost a. Hautefeuille, A. Ch. [5] 7, 459).

Properties. — A colourless, mobile liquid, boiling at 146°-148°; S.G. 1.58 at 0°; solidifies st. 14° to large leaflets, which melt at 1° (F. a. L., l.c.). V.D. 140 at c. 240° (T. a. H., l.c.). Fumes in air, de imposed by water; vapour takes fire when Si_.Cl₄ is heated in air.

Reactions and Combinations.—1. Decomposed to SiCul and Combinations.—1.

posed to SiCl, and Si by heat in a closed tube; decomposition is extremely slow at 350°, nearly complete at 800°; heated rapidly above 1000° the dissociation-pressure falls: the compound is stable below 350° and above 1000° (T. a. H., l.c.).—2. Decomposed by water. At ordinary temperatures products remain in solution, and are ppd. by NH₃Aq; at 0° Si₂H₂O₄ is formed (v. Silico-oxalic acid, p. 463) (F. a. L., l.c.).— 3. Caustic potash forms SiO₂ and gives off H (F. a. L., A. 203, 254) .- 4. Phosphorus hydride is changed to the solid hydride at -10° (Besson, C. R. 110, 516).-5. Combines with ammonia to form Si,Cls.5NH, (B., l.c.).

SILICON TETRACHLORIDE SiCl. 169.78. Boils at 57.57° at 760 mm. pressure (Thorpe, C. J. 37, 327). S.G. 30 1.52408 (T., l.c.). V.D. 85.5 at 100° (Dumas, A. Ch. [2] 33, 368). S.H. of SiCl, vapour, at 90° to 234°, = 1322, at constant pressure, referred to equal weight of water; 12, at constant volume, referred to equal weight of water (Regnault, Acad. 26, 1). Regnault (l.c.) gives the vapour-pressures of SiCl, as follows:—

Temp.	•	Vap	our-pro	essure.
-20°.		. 26.49	mm.	mercury
-10.		. 46.46	"	,,
0.	•	. 78.02	"	,,
+10 .	•	. 12 5·90	,,	,,
20 .	•	. 195.86	"	**
30 .	•	. 294·49	,,	**
40.	•	. 429.08	"	,,
50 .	•	. 607·46	**	**
60 .		. 837.23	,,	,,

H.F. $[Si,Cl^4] = 157,640$ (Troost a. Hautefeuille, A. Ch. [5] 9, 70).

Formation.-1. By passing dry Cl, or HCl gas, over a mixture of SiO, and C at full red heat (Oerstedt, B. J. 6, 119; Deville, A. Ch. [3] 43, 23). According to Weber (P. 112, 649) C is not necessary if the temperature is high enough. 2. By heating crystalline Si, or Si containing H, in Cl (Berzelius, C. J. 4, 91).—3. Favre (C. R. 107, 339) heats impure Si, and passes HCl and vapour of naphthalene over it.—4. By heating iron containing c. 15 p.c. Si in Cl (Warren, C. N. 60, 158).—5. By passing vapour of BCl_3 over SiO_2 heated to dull redness $(4BCl_3 + 3SiO_2 = 3SiCl_4 + 2B_2O_3$; Troosta Hautefeuille, A. Ch. [5] 7, 476).

Preparation.-1. Amorphous SiO, is mixed with an equal weight of lampblack, and the mixture is made into a paste with oil. Small pellets are made of this paste; these are imbedded in charcoal powder, and strongly heated. The dry pellets are placed in a porcelain tube, which is heated to very bright redness in a furnace while a stream of Cl (dried by H₂SO₄ and then by CaCl.) is passed through. The exit end of the porcelain tube is connected with a U-tube, from the bottom of the bend of which a short tube passes down into a small flask; the U-tube and small flask are surrounded by a freezing mixture. The SiCl, which condenses in the flask is shaken in a dry flask with Hg and a few pieces of K, and then distilled with sodium.

L. Meyer (A. 270, 238) recommends the use of charcoal-powder in place of lampblack, and starch-paste rather than oil.—2. Gattermann (B. 22, 186) places impure amorphous Si (containing some Mg, &c.), prepared as described under Silicon, Preparation, No. 1, in a tube c. 2 cms. wide, leaving a space of c. 1 cm. above the Si along the tube; he bends this tube at right angles, and connects it with a U-tube placed in a freezing mixture; he then passes dry Cl through the apparatus, while he heats the tube, laid in an iron trough in a gas-furnace so that the tips of the flames just touch the iron trough. The temperature must not get too high, else the Si glows, and MgCl, and O are formed, and the O oxidises the Si to SiO.

Properties.—A colourless, very clear, and very mobile liquid, with a disagreeable odour resembling that of cyanides; reddens litinus; Does not become viscid fumes in moist air.

at -75° (Haase, B. 26, 1052).

Reactions and Combinations .- 1. Heated to redness with hydrogen a little SiHCl, is formed (Friedel a. Ladenburg, Bl. [2] 12, 92).-2. Oxychlorides are produced by the action of oxygen under the influence of induction sparks (Troost a. Hautefeuille, A. Ch. [5] 7, 465).—3. SiCl, is decomposed by passing the vapour with dry air through a white-hot tube, giving Si_2OCl_a and Cl (F. a. L., *l.c.*). Berthelot (A. Ch. [5] 15, 185) says that SiO_2 is also produced. 4. Water produces H.SiO, and HClAq .- 5. Hydrogen sulphide forms SiCl, SH, when SiCl, and H,S are passed through a red-hot tube (F. a. L., A. 145, 179; Pierre, A. Ch. [3] 24, 300). 6. Many metals-e.g. K, Na, Zn, Ag-withdraw all Cl from SiCl, when heated to redness in vapour of SiCl, (F. a. L.; cf. Rauter, A. 270, 235). 7. Most metallic oxides form SiO, and metallic chlorides when heated with SiCl, (R., l.c.); CaO, MgO, Al₂O₃, and BeO form silicates and crystalline SiO₂ (Daubrée, C. R. 39, 135); TiO₂ is not changed (T. a. H., A. Ch. [5], 7, 476).—8. Decomposed by heating with alkali carbonates, potassium chlorate or nitrate, and various oxidising salts (R., l.c.) .- 9. SiO2 and HCl are produced by reaction with sulphuric acid. -10. Ammonia forms SiCl. 6NH, (Persoz, A. Ch. [2] 44, 315); also, according to Gattermann (B. 22, 194), Si.NH, N.-11. Phosphoretted hydro. gen does not react at ordinary temperatures; but at -40° c. 40 vols. of PH, are absorbed by SiCl,, forming a solution which does not solidify at -60° (Besson, C. R. 110, 240). A colourless crystalline compound is produced by compressing PH3 and SiCl, and then decreasing pressure to 20 atmospheres at 10° (B., l.c.).—12. Heated with sodium silicate, NaCl is formed. If SiCl, vapour is passed through a tube containing fragments of felspar, at a white heat, KCl, SiO2, and Si,OCl, are formed (F. a. L., l.c.).

For the compound SiHCl, v. SILICO-CHLORO-

говм, р. 453.

? SILICON DICHLORIDE SiCl. In the preparation of Si_.Cl_s by the reaction of SiCl_s with Si, Troost a. Hautefeuille (A. Ch. [5] 7, 463) obtained a liquid which took fire when heated in air, and reacted with ice-cold water to form a hydroxide of Si having reducing properties.

Silicon, chlorobromides of, v. Silicon Bromo-

CHLORIDES, p. 458.

Silicon, chlorohydrosulphide of, SiCl, SH. (Trichloro-silico-mercaptan.) Mol. w. 167-39. This compound may be looked on as a derivative of hypothetical ortho-thio-silicic acid Si(SH),, obtained by replacing 3SH by 3Cl.

Prepared by passing dry H.S into SiCl, in a

retort, and then passing the mixed vapours of H.S and SiCl, through a red-hot porcelain tube connected with a receiver surrounded by a freezing mixture, and fractionating the liquid that condenses (Friedel a. Ladenburg, A. 145, 179). Colourless liquid, with sharp, disgusting smell; boils at 96°; S.G. 1.45. V.D. 83.5 at c. 167°. Decomposed by moist air, more rapidly by water, to H₂S, S, HClAq, and SiO₂xH₂O; bromine produces SiBrCl₃ and HBr. Alcohol in excess forms Si(OEt), H₂S, and HCl; by reacting in the ratio 3EtOH: SiCl₂SH, F. a. L. (l.c.) obtained a liquid boiling at 164°-167°, probably Si(OEt) SH; this liquid could not be obtained pure, as it changed to Si(OEt), HCl, and H.S.

Silicon, chloro-iodides of, v. Silicon iodo-

CHLORIDES, p. 461.

Silicon, compounds of, with carbon and oxygen. According to Colson (Bl. [2] 38, 56), the compound SiCO, is formed by heating Si with benzene vapour, the compound Si₂C₃O₂ by heating Si to whiteness in a carbon crucible, and

the compound Si₂C₂O by heating Si in CO₂.
Silicon, compound of, with carbon and sulphur. Colson (Bl. [2] 38, 56) says that a compound, to which he gives the formula Si,C,S, is produced by heating Si to a white heat

in CS. vapour.

Silicon, compounds of, with hydrogen and oxygen. The compounds of the form SiO, xH,O are described under SILICA, HYDRATES OF (p. 447); the compounds Si₂H₂O₃ and Si₂H₂O₄ are described as silico-formic anhydride and silicooxalic acid respectively (pp. 455, 463). Wöhler (A. 127, 257) obtained a substance, by the decomposition of impure Ca silicide by HClAq, to which he gave the name silicone, and either the composition Si₄H₄O₃ or Si₃H₃O₂. On account of the yellow colour of this body, Miller proposed to call it chryscone. Silicone is described as orange-yellow leaslets, insol. water, alcohol, CS, SiCl, or PCl; when heated below redness it takes fire, burning to SiO, and amorphous Si; heated out of air, H is given off and SiO₂ and amorphous Si remain; not acted on by Cl, fuming HNO₃, or conc. HSO₄; caustic alkali solutions, even dilute NH, Aq, produce SiO, with rapid evolution of H; acts as an energetic reducer towards solutions of many metallic salts.

Silicon, fluorides of. The existence of any compound of Si and F except SiF, is doubtful. Troost a. Hautefeuille (A. Ch. [5] 7, 464) obtained a fine dust by passing SiF, over molten Si and suddenly cooling, which was probably a lower fluoride than SiF.

SILICON TETRAFLUORIDE SiF. Mol. w. 104.3. Formation.—1. By passing BF, vapour through a red-hot porcelain tube (Troost a. Hautefeuille (A. Ch. [5] 7, 464).—2. By the interaction of HFAq and SiO2 or silicates.

Preparation. -A fair-sized flask is one-third filled with a mixture of equal parts of powdered CaF, and quartz or white sand; sufficient conc. H.SO, is added to thoroughly moisten the mixture; the flask is gently warmed, and the gas that comes off is collected over Hg

 $(2CaF_2 + 2H_2SO_4 + SiO_2 = 2CaSO_4 + 2H_2O + SiF_4)$. Properties.—A colourless gas, with a dis-greeable odour and sour taste; reddens dry litmus paper; fumes strongly in air. V.D. 51-9 (Dumas, A. Ch. [2] 83, 368). Condensed to a colourless mobile liquid at -106.5° and 9 atmospressure (Faraday, T. 1845, 155). According to Olszewski (M. 5, 127) SiF₄ solidifies at -102° . Acts as a powerful poison (v. Cameron, Dublin

J. of Med. Sci. Jan. 1387).

Reactions.-1. Decomposed by electric sparks with separation of Si (T. a. H., C. R. 43, 443).-2. Potassium and iron, when hot, burn in SiF,, forming fluorides and Si.—3. Moist air forms Si,O,F.OH (Landolt, A. Suppl. 4, 27, and v. DIMETASILICIO FLUORHYDRIN, infra).—4. Water absorbs SiF., forming SiO.xH.20 and H.SiF.Aq (v. SILICOFLUORHYDRIC ACID, p. 454).-5. Ammonia forms SiF₄.2NH₃ (J. Davy, T. 1812. 352); also, according to Harris (C. C. 1889 (ii.) 283), SiNH, N (v. SILICON AMIDONITRIDE, p. 457).

Combinations. - 1. Combines with dry phosphoretted hydrogen, when the gases are strongly compressed at -22° and 50 atmospheres in the ratio 2PH₃:3SiF₄, to form lustrous crystals (Besson, C R. 110, 80).-2. Alcohol absorbs SiF₄ freely, forming an acid liquid which gives off SiF₄ in the air (Knop, J. 1858, 146).—3. SiF₄ is absorbed by many metallic oxides.

Dimetasilicic fluorhydrin Si₂O₂OH.F. Landolt (A. Suppl. 4, 27) obtained this compound as a white crystalline solid (v. also Schiff,

J. 1865. 196).

Silicon, haloid compounds of. The com-pounds of Si with halogens belong to the forms Si₂X₆ and SiX₄; the compounds SiX₄, where X is a single halogen, have been gasified, and the compound Si₂Cl₈ has also been gasified. The formulæ are probably all molecular. There are also indications of the existence of some compounds of the type SiX₂. Besides the compounds where X is a single halogen, there exist the compounds SiXX'₃, SiX₂X'₂, and SiX'X₃, where X and X' are Br and Cl, I and Cl, and I and Br respectively; the only one of these compounds that has been gasified is SiBr,Cl.

Silicon, hydrides of. The compound SiH, has been isolated and examined. The existence of another hydride, probably SigHg, is

likely.

SILICON TETRAHYDRIDE SiH. (Silicitretted hydrogen.) Mol. w. 32·3. Si and H do not combine directly, even in the electric arc (Friedel, C. R. 73, 497).

Formation.—1. Al containing Si is made the positive pole in NaClAq (Buff a. Wöhler, A. 103, 218).—2. Crude Mg silicide is decomposed by dilute HClAq (v. Preparation). These processes yield mixtures of SiH, and H.—3. By the reaction of Na with SiH(OEt), (v. Prepara-

tion).

Preparation .- 1. Small pieces of Na are dropped into SiH(OEt), (v. infra), and the liquid is gently warmed; the escaping gas is allowed to drive out the air (if the Na or SiH(OEt), was moist H comes off, and the gas takes fire), and is then collected over Hg (Friedel a. Ladenburg, 143, 123). The SiH(OLt), is prepared by adding dry absolute alcohol to pure SiHCl, in a longnecked flask, in the ratio 3EtOH : SiHCl_s, distilling after some time, and collecting the liquid that boils from 134° to 137°.-2. Impure SiH,, mixed with considerable quantities of H, is prepared by placing coarsely-pulverised crude Mg silicide (for preparation, v. infra) in a small

two-necked flask, fitted with a funnel tube and a short wide delivery tube; the flask and de-livery tube are quite filled with water from which all air has been driven out by boiling, the delivery tube is made to dip under boiled water. and the bell-jar to receive the gas is filled with boiled water; conc. HClAq is added, little by little, by the funnel tube. The gas, which comes off very rapidly, is collected in a bell-jar fitted with a stop-cock; this jar is then connected with a U-tube containing CaCl, and carrying a short, narrow piece of glass tubing, which is made to dip under a dry vessel full of Hg. By depressing the bell-jar, the gas is forced out; it burns in the tubes till the air is exhausted, when it passes into the vessel full of Hg, where it is collected.

Preparation of the crude Mg silicide. A mixture of 1 part finely-powdered, dry, white sand and $1\frac{1}{2}$ parts Mg powder is heated in a stout glass tube; reduction takes place with production of much light, and a bluegrey, semi-molten mass is obtained (Gattermann, the Mg silicide required, v. Wöhler (A. 137, 369), Warren (C. N. 58, 215), and Mermet (Bl. [2] 47, 366).

Properties .- A colourless gas; insol. water; liquefied at -11° and 50 atmos., -7 and 70 atmos., or -1° and 100 atmos. pressure (Ogier, A. Ch. [5] 20, 5). V.D. 15.9 (F. a. L., A. 143, 123). H.F. [Si,H⁴] = 32,900 (O., l.c.). Does not react with N, NO, NH₃, H₂SO₄Aq, or HClAq.

Reactions.—1. Decomposed completely to Si

and II by heating to above 400° (O., l.c.). 2. Induction sparks cause increase of volume from 100 to 121-129; H is produced, and yellow solid separates, probably Si_.H₁ (v. Disilicon tri-Hydride, infra). --3. SiH₁ takes fire in air when slightly heated, or when the pressure is decreased; if the pure gas is passed into a tube filled with Hg, the pressure is lowered to 100-150 mm., and air is admitted, the gas takes for (F. a. L., l.c.). The gas as prepared from Mg silicide is mixed with H, and takes fire in air at ordinary temperature and pressure.-4. Burns in chlorine with violent explosion .-5. Conc. potash solution forms K.Sio, and H; the volume of H is four times that of the SiH, (SiH₁ + 2KOHAq + H₂O = K₂SiO₂ + 8H) (F. a. L., l.c.).-6. Reduces solutions of many metallic salts; ppts. Ag and Si from AgNO, Aq, Pd from Pd salts, Cu silicide from CuSO, Aq, &c. Does not react with PtCl, Aq or Pb(C, H, O,), Aq.— 7. The action of electric discharges on SiH. mixed with nitrogen produces NH,, and (?) Si₂H, which combines with some of the N (Ogier, A. Ch. [5] 20, 31).

Disilicon TRIMYDRIDE Si₂H₃. This formula is given by Ogier (A. Ch. [5] 20, 31) to a yellow solid obtained by the action of induction sparks on SiH. The composition of the substance is somewhat doubtful. It takes fire when rubbed or heated in air; heated in H or N, inflammable SiH, is produced, or at higher temperatures Si

and H are formed.

Silicon hydrogen bromides v. Silico-Bromo-FORM, p. 453, and SILICO-ETHANE, PENTABROMO-DERIVATIVE OF (Si.HBr.), p. 454.
Silicon hydrogen chloride v. Silico-chloro

FORM, p. 453.

Silicon, hydroxides of, v. Silica, hydrates of, p. 447; Silico-formic acid, p. 455; Silico-formic ametardre, p. 455; Silico-formic ametardre, p. 455; Silico-oxalic acid, p. 463; and Silicone, under Silicon, compounds of, with hydrogen and oxygen, p. 459.
Silicon, iodides of. Two compounds have

Silicon, iodides of. Two compounds have been isolated, SiI, and Si₁I₆, and a third, which is probably SiI₂, seems also to exist.

SILICON TETRA-IODIDE SII. Mol. w. 534'42. Melts at 120'5°; boils at 290°. V.D. at 360° = 268'5. H.F. [Si,F⁴] = 58,000 (Berthelot).

Preparation.—1. The crude product obtained by reducing a mixture of 4 parts fine white sand by heating with 1 part Mg powder (v. SILLCON, Preparation of, No. 1, p. 456) is strongly heated in a mixture of dry CO, and I vapour, in a tube which projects c. 20 cm. .rom the furnace; Sil, collects in the cold part of the tube, it is dissolved in CS₂ (1 part CS₂ dissolves c. 2·2 parts SiI₄), shaken with Hg till colourless, and the CS₂ is evaporated by passing dry CO₂ through it at the lowest possible temperature (Gatternann, B. 22, 190).—2. A mixture of CO₂ and I vapour is passed over Si strongly heated in a porcelain tube; the SiI₄ that collects in the cold part of the tube is purified as in 1 (Friedel, A. 149, 96).

Properties and Reactions.—Colourless, transparent, regular octahedra; isomorphous with CI₄. (For M.P., &c., v. supra.) The vapour burns when heated in air, with separation of I. Water produces SiO₂xH₂O and HIAq. Alcohol forms EtI, HI, and SiO₂. Ether, at 100°, produces Si(OEt), and EtI (F., l.c.).

SILCON HEXA-IODIDE Si.L. Formula probably molecular, from analogy of Si.Cl. Prepared by heating SiI, with finely-divided Ag (formed by reducing AgCl) to 290°–300° for some hours, removing SiI, by washing with a little dry CS₂ (1 part CS₂ dissolves c. '26 parts SiI, and c. 2'2 parts SiI,), dissolving in much hot CS₂, and crystallising (Friedel a. Ladenburg, 4. 203, 254). Colourless, six-sided, double refractive plates. Melts at 250° in vacuo, with partial decomposition. When heated, decomposes to SiI₄, and a substance that is probably SiI₄. Fumes in air; with water gives H₂Si₂O₄ and HIAG.

SILION DI-IODIDE. The yellow solid that is formed by heating SiI, is probably SiI,; it is insol. in the ordinary solvents; with water becomes grey, perhaps forming H₂SiO₂ (v. Silico-forming ACID, p. 455) (Friedel a. Ladenburg, A. 203, 247).

For the compound SiHI, v. Silico-iodoform, p. 455.

Silicon, iodobromides of. Three compounds, corresponding with the three bromochlorides and the three iodochlorides, are formed by passing IBr (alone or mixed with H) over crystalline Si heated to dull redness; also by passing the vapour of a solution of I in SiBr, over crystalline Si at a low red heat (Besson, O. R. 112, 1447). The compounds are solids which decompose in air with separation of I; they all combine with NH, to form white compounds that are decomposed by water.

SILICON IODOTRIBROMIDE SiIBr_s. Melts at 14° and boils at 192°. Prepared as described above, also (probably) by the interaction of I and

SiHBr_a at 200°-250°, also by passing HI over SiBr_a heated to low redness (B., *l.c.*).

SILICON DI-IODODIBROMIDE Sil₂Br₂. Melts at c. 88° and boils at 230°-231°. SILICON TRI-IODOBROMIDE Sil₂Br. Melts at

c. 55° and boils at c. 255°.

Silicon, iodochlorides of. Three compounds have been isolated, corresponding with the three bromochlorides, and the three iodobromides. The V.D. of none has been determined, but from the analogy with the bromochlorides the simplest formulæ are probably molecular.

SILION IDDOTRICHLORIDE SIICI₃. Obtained by passing HI mixed with SiCl₄ vapour through a red-hot tube, also by the interaction of HI and SiHCl₅ at 200°-250°, also by distilling ICl over crystallised Si heated to redness (Besson, C. R. 112, 60, 1314). A colourless liquid, boiling at 113°-114°; fumes in air; decomposed by water; I separates on standing, especially in sunlight. With NH₃ forms white amorphous 2SilCl₃.11NH₄.

SILICON DI-IODDICHLORIDE SIL, Cl., Formed from HI and SiCl., also from ICl and Si; also by heating HI with Sil, Cl at 2502. Colourless liquid, boiling at 172°. With NH4 forms amorphous SiL, Cl., 5NH4 (B., Lc.).

SILICON TRI-IODOCHLORIDE SII,Cl. A solid obtained in preparation of the two former compounds; melts at 2°. Fumes in air, with separation of I.

Silicon, nitrides of. Schutzenberger (C. R. 114, 1089) obtained small quantities of a compound to which he gave the formula Si,N., along with a carbide of Si, by heating 1 part Si and 2 parts SiO, in a covered carbon crucible, imbedded in lampblack in an outer crucible, imbedded in lampblack in an outer crucible, imbedded in Porcelain tube kept at a white heat, Colson (C. R. 94, 1710) found a black layer in the hottest part of the tube, which was probably a mixture of Si and nitride of Si. A compound of Si, N, and H, probably Si.NH₂,N, was obtained by Harris (C. C. 1889 (ii.) 283) by the reaction of NH₂, with SiCl, or SiF₄. Silicon, oxide of, SiO₂; v. Shlea, p. 446.

Silicon, oxide of, SiO₂; v. Silico, p. 446.
Silicon, oxychlorides of. The compound
Si₂OCl₆ is formed by heating SiCl₄ vapour in air
or O. According to Troost a. Hautefeuille
(Bl. [2] 35, 360) several oxychlorides are formed
by passing a mixture of SiCl₄ vapour and O
through a red-hot tube, or, better, by passing a
mixture of 1 vol. Cl and ½ to ½ vol. O over crystalline Si heated to not above 800°. T. a. H.
isolated the following oxychlorides:—

Si,O,Cl₁₀; liquid, b.p. 1522–154°, Si,O,Cl₁₀; liquid, b.p. 198°–202°. Si,O,Cl₂; cily liquid, b.p. above 400°. Si,O,Cl₂; solid, m.p. above 400°.

SILICON OXYCHLORIDE SLOCI. (Perchlorosilico-methyl ether (SiCl₃).O.) Mol. w. 28478. Prepared by passing vapour of SiCl₄ through a porcelain tube heated in a wind furnace burning coke, condensing the product, repeating the operation with the portion which boils above 70°, fractionating, and separating the liquid boiling at 187°-178° (Friedel a. Ladenburg, 4. 147, 365). A colourless liquid, boiling at 137°-138°. V.D. 144 at c. 200°. Furnes in air, decomposed by water to HClAq and SiO₁₀-HO. Miscible in all proportions with OHCl₂, CCl₄, OS₂₀ SiCl, and Et.O. Alcohol produces Si₂O₇(Et),; zinc ethide at 180° forms SiEt, and Si OEt, (F. a. L., l.c.)

The compound SiP,O,Cl, is described as SILICOPHOSPHORIC OXYCHLORIDE (p. 461).

Silicon, oxysulphide of. According to Colson (Bl. [2] 38, 56), a compound SiOS is formed, along with SiS and Si₄SC₄, by heating Si to white

heat in CS₂.
Silicon, sulphides of. The only compound of Si and S certainly isolated is SiS2. Colson (Bl. [2] 88, 56) says that silicon monosulphide, SiS, is produced, along with SiOS and Si, SC., by heating Si to white heat in CS₂; he describes SiS as a yellow solid, decomposed by water giving off H₂S, sol. in very dilute KOHAq with evolution of H. SiS is also said to be formed, along with SiS, by heating Si to redness in H_2S (Sabatier, Bl. [2] 38, 153).

SILICON DISULPHIDE SiS2. Mol. w. not determined. Sabatier (Bl. [2] 38, 153) gives H.F. [Si,S²] = 19,900. Amorphous Si and S combine when strongly heated (Berzelius). Prepared by heating Si to redness in a stream of dry H2S; the other products are a yellow solid, probably SiS, and a brown substance that is likely a mixture of SiS, and SiS, or of SiS, and Si (S., l.c.; v. also Fremy, A. Ch. [3] 38, 324). Also prepared by strongly heating dried pellets of oil and SiO2 (separated from SiF4) in a slow stream of dry CS₂, quickly separating the white needles that form on the cooler part of the tube, and keeping in a closed tube (Fremy, *l.c.*). The residue that remains on distilling the products of the interaction of SiCl, and H₂S (v. Silicon Chlorohydrosoulphide, p. 459) contains SiS, and S; S may be removed by carefully heating in a stream of N (Gay-Lussac a. Thénard, A. Ch. [2] 69, 204). Long, lustrous, white needles; volatilised at very high temperatures (Fremy, l.c.). Unchanged in dry air at ordinary temperatures; decomposed by moist air to H₂S, and crystalline SiO₂ pseudomorphous with SiS2; burns to SO2 and SiO2 when heated in air. Decomposed rapidly by water to SiO₂xH₂O and H₂S; also decomposed by alcohol and ether (Fremy, l.c.). HNO, oxidises rapidly, producing H.SO. M. M. P. M.

Silicon, sulphocyanide of; v. p. 463. SILICON, ORGANIC COMPOUNDS OF.

Silicic ethers are described elsewhere -v. AMYL, AMYLPHENYL, ETHYL, METHYL, PHENYL, THYMYL, TOLYL, and XYLYL SILICATES.
Tetra-methyl-silicane SiMe. • Mol. w. 88.

(31°). V.D. 3·08 (calc. 3·04). Formed by heating SiCl, with ZnMe, at 120° (Friedel a Crafts, A. 136, 203). Light oil, burning with bright flame emitting SiO2. Not attacked by potash or HNO, (S.G. 1.4).

Mol. w. 144. Tetra-ethyl-silicane SiEt,. (153°). V.D. 5·13 (calc. 4·99). S.G. 2·834. Prepared by heating SiCl, with ZnEt, at 160°. Formed also by the action of ZnEt, and Na on ethyl silicate (Friedel a. Crafts, Bl. 1863, 468; 1865, 358; A. 127, 31; 138, 19). Oil, insol. H.SO. Chlorine forms liquid Et.SiC.H.Cl (185°), converted by alcoholic KOAc at 180° into Et,SiC,H,OAc (2080-2140), whence alcoholic

Formed by distilling Si, I, with ZnEt, (Friedel a. Ladenburg, A. 203, 251). Oil, burning with bright flame.

'Silicopropionic acid' EtSiO.OH. Got by heating its ortho- ether with HIAq (Ladenburg, A. 159, 271; 164, 305). Amorphous powder, insol. water and Na CO Aq, sol. conc. KOHAq.

Methyl ortho- ether EtSi(OMe),. (126°). S.G. 2 9747. Formed from Si(OMe), sodium, and ZnEt, (Ladenburg, B. 5, 1081). Oil.

Ethyl ortho-ether EtSi(OEt), (159°).
S.G. 2 927. Formed by the action of Na and

ZnEt, on ClSi(OEt), or Si(OEt), Oil. Converted by BzCl into EtOBz and EtSiCl, (100°), which fumes in the air and is converted by water into silicopropionic ether.

'Silicodiethyl ether' Et2Si(OEt)2. (156°). V.D. (H=1) 87 (calc. 88). S.G. 9 ·875. Formed from Na, ZnEt₂, and silicic ether. Oil, sol. alcohol and ether. AcCl (1 mol.) at 200° forms EtOAc and Et₂SiCl(OEt) (147°). A larger quantity (2 mols.) of AcCl at 250° forms Et.SiCl₂ (129°), which is decomposed by water, forming syrupy SiEt₂O (above 360°), which may also be got by boiling SiEt, (OEt), with HIAq.

'Silicoheptyl ether' SiEt. OEt. Mol. w. 160. (153°). S.G. $\stackrel{4}{\sim}$ *840. V.D. (H = 1) 80°8 (calc. 80). Formed from SiEt. (OEt)₂. Na, and ZnEt₂. Oil, sol. alcohol and ether. Sol. conc. H₂SO₄. AcCl at 180° forms SiEt₃Cl (144°), S.G. SiEt,OH.

Tri-ethyl-silicol SiEt,OH. Mol. w. 132. (154°). S.G. 2 871. Formed by dropping SiEt, OEt into NH, Aq, or by heating it with Ac, O at 250° and decomposing the resulting SiEt₃.OAc with Na₂CO₃Aq. Thick liquid, smelling like camphor. Insol. water, miscible with alcohol and ether. Burns with bright flame. Sodium forms SiEt, ONa, which, in ethereal solution, combines with CO2, forming SiEt3, CO2Na, an amorphous deliquescent solid, decomposed at a red heat into Si₂Et_aO and Na₂CO₃. AcCl forms HOAc and SiEt₃Cl. HIAq at 200° forms ethane and SiEt₂O. Oxidising agents have no action. Fuming H2SO4 forms EtSiO2H, ethane, H, and SO4

Acetyl derivative SiEt₃OAc. (168°). S.G. ²·903. Formed by heating SiEt₃.OEt with Ac₂O at 250°. Liquid with ethereal odour.

'Silicoheptyl oxide' (SiEt₃)₂O. Mol. w.246.

(231°). S.G. 2 859. Formed as above, and also by the action of P2O, on tri-ethyl-silicol. Got also from SiEt, Cl and KOHAq. Colourless syrup, sol. H.SO, and separated unchanged on dilution, if heating be avoided.

(107°). S.G. (8). Formed, Tri-ethyl-silicane SiEt.H. ² ·751. V.D. (H = 1) 59 (calc. 58). together with SiEt,, by the action of excess of ZnEt, and Na on Et,SiO,. Liquid, insol. water and H.SO,, sol. alcohol and other. Fuming H₂SO, converts it into (SiEt₃)₂O. HNO₃ attacks it vigorously. Bromine added slowly to the cooled liquid forms SiEt₃Br (161°), which is converted by NaOHAq into (SiEt,),O, and by NH3Aq into SiEts.OH.

Bilicoformic acid. Ethyl ortho- ether SiH(OEt)3. (134°). Formed from SiHCl2 and Dotash at 120° forms oily Et. SiC.H.OH (190°).

Hexa-ethyl di-silicane Si.Et. (252°).

S.G. § 851; 38 840. V.D. 8.6 (calc. 7.96). Hygroscopic liquid, decomposed by alkalis with absolute alcohol (Friedel a. Ladenburg, A. 143, 123; Bl. [2] 7, 322; Gattermann, B. 22, 190). svolution of H. Sodium decomposes it into

SiH, and Et,SiO,.

Chloro-silicoformic ether v. ETHYL SILICATE. 'Silicoacetic acid.' Ethyl ortho- ether CH₃.Si(OEt)₃. (145°-151°). S.G. 2 .928. Formed by heating silicic ether with ZnMe. Oil, sol. alcohol. Converted by HIAq into amorphous silico-acetic acid CH., SiO., H., which is insol. water and ether (Ladenburg, B. 6, 1029).

The term silicoacetic acid is also sometimes used to denote $H_2\mathrm{Si}_2\mathrm{O}_3$, which is got by decomposing $\mathrm{Si}_4\mathrm{I}_5$ by water at 0° (Friedel a. Ladenburg, $A.\ 203,\ 249$; $v.\ \mathrm{Silico-oxalic acid,}\ infra). A compound <math>\mathrm{Si}_2\mathrm{O}_3\mathrm{O}_2$ is formed, as a bottle-green powder, by heating silicon to whiteness in a

crucible lined with lampblack. It is insol.

KOHAq and HFAq (Colson, C. R. 94, 1316).

Tetra-propyl-siticane Si(C₂H₁), (213°).

S.G. ² 7979; ¹⁵ 7883. V.D. 99.7 (obs.).

Formed, together with SiHPr₃, by heating ZnPr₂. (2 pts.) with SiHCl, (1 pt.) at 150° (Pape, B. 14, 1872; A. 222, 370). Colourless oil, sol. alcohol, and ether, insol. H₂SO₄. Br has no action in Colourless oil, sol. alcohol. the cold, but on warming it forms oily SiC₁₂H₂,Br, converted by alcoholic potash into oily SiC₁₂H₂₆ (206°-210°).

Tri.propyl-silicane SiHPr_s. (170°). S.G. 7723; ¹⁵ 7621. V.D. 82 (obs.). Formed as above. Oil, v. sol. alcohol and ether, insol. Formed conc. H2SO4. Burns with bright flame, forming SiO₂. Br acts violently, forming SiPr₃Br (213°), a fuming liquid, which is slowly converted by

water into SiPr. OH.

Tri-propyl-silicol SiPr₃.OH. (205°-208°). Formed by the action of NH3Aq on SiPr3Br, or of Na₂CO₃Aq on SiPr₃.OAc (Pape). Oil.

Acetyl derivative SiPr. OAc. 216°). Formed from SiPr, Br and AgOAc. Oil.

Hexa-propyl-di-silicyl oxide (SiPr₃)20. (280°-290°). Formed by warming SiHPr, with H₂SO₄ and, together with SiPr₈.OH, by boiling SiHPr, with Na₂CO₃Aq (Pape, A. 222, 369). Liquid, sol. alcohol, ether, and H₂SO₄.

Silicon sulphocyanide Si(CNS). (c. 300°). Formed by distilling lead sulphocyanide with SiCl, (Miguel, A. Ch. [5] 11, 343). Colourless prisms, insol. ether and CS₂, soluble in a solution of HCNS in benzene. Burns with violet flame. Dyes the skin red. Decomposed

by water into HCNS and SiO...

Tetra-phenyl-silicane SiPh.. [233°]. (above 860°). S.G. 20 1.0780. Formed from chlorobenzene, SiOl., and Na in presence of a little EtOAc (Polis, B. 18, 1540; 19, 1012; 20, 3331). Dimetric crystals; a:o=1:440, sol. hot benzene, sl. sol. alcohol and ether. May be sublimed. Sulphonated by fuming H2SO4. HNO8 forms Si(C₄H₄,NO₂), [105°], a yellow powder, v. sol. benzene. Converted by PCl₃ into liquid SiPh₂Cl₂ (234° at 90 mm.) and SiPh,Cl [89°], from which water produces tri-phenyl-silicol SiPh, OH [141], which separates from ether in colourless crystals.

Phenyl-tri-chloro-silicane SiPhCls. (197°). Formed by heating SiCl₄ with HgPh₂ at 300° (Ladenburg, B. 6, 379). Oil. Decomposed by hot water, or by NH₂Aq, yielding 'silicobenzoic acid' SiPh(OH)₂ [92°]. Absolute alcohol forms 'silicobenzoic' ethyl ortho- ether SiPh(OEt)₂ (237°). S.G. 2 1.018; ¹² 1.006. Silicobenzoic acid is converted at 100° into amorphous 'ailicobenzoic anhydride' (SiPhO),O.

Phenyltriethyl-silicane SiPhEt. S.G. 2 904. Formed, together with SiEt, and SiPh₂Et₂ (c. 810°), by heating SiPhCl₃ with ZnEt₄ at 150°. Oil, smelling like cloves. Yields a bromo-derivative (270°-280°). Ol forms SiC₁₂H₁₃Ol (260°-265°), S.G. 2 1 0185.

Tetra-m-tolyl-silicar : Si(C.F) (above 550°). S.G. 20 1.119. .med from m-bromo-toluene, SiCl,, and Na (Polis, B. 19, 1021). Pale-yellow needles (from ether), v. sol. benzene and chloroform, insol. alcohol.

Tetra-p-tolyl-silicane Si(C,H_r)₄. [228°]. (above 360°). S.G. ²² 1-079. Formed from p-bromo-toluene, SiCl₄, and Na (Polis, B. 18, 1542). Colourless crystals, sol. benzene.

p-Tolyl-tri-chloro-silicane C,H,SiCl₂. (219°).
Formed from Hg(C,H₂), and SiCl₄ at 310° (Ladenburg, A. 173, 165). Fuming liquid, decomposed by water. Converted by NH₃Aq into viscid C,H,SiC₂H, which is converted at 200° into the solid anhydride (C,H,SiO),O, which is not melted at 200°.

Tetra-benzyl-silicane v. vol. i. p. 502.

Silicon tetra-phenyl-tetra-amide Si(NHPh)4. [138°]. Formed from SiBr, and excess of aniline diluted with benzene, the product being distilled in a current of H at 105° (Reynolds, C. J. 55, 477). Colourless monoclinic crystals; $a:b:o = 985:1:1\cdot043$; $\beta = 110^{\circ}20'$. V. sol. benzene, sol. CS., insol. ligroin. Decomposed by water and alcohol. Not decomposed by heating at 210°. HCl forms SiCl, and aniline.

Silicon di-chloro-di-phenyl-di-amide SiCl₂(NHPh)₂. Formed from SiCl, and aniline (Harden, C. J. 51, 40). Amorphous solid. Decomposed by water into aniline hydrochloride and silica.

Silicon tetra-o-tolyl-tetra-amide

Si(NHC,H,)₄. Formed from SiCl₄, o-toluidine, and benzene (Reynolds). Prisms, v. sol. benzene and CS₂. The compound SiCl₂(NHC,H,)₂, which is also formed from SiCl, and o-toluid-ine, is a white granular powder (Harden).

Silicon tetra-p-tolyl-tetra amide

Si(NHC,H₁), [132°]. Formed from SiCl, and p-toluidine in benzene (Reynolds). Botryoidal aggregate of needles, v. sol. benzene and ether, decomposed by water and alcohol.

Silicon tetra-naphthyl-tetra-amide Si(NHC₁₀H₁). Formed from (\$\beta\$)-naphthylamine and SiCl₄ (R.). Nodules, decomposed by water. Sl. sol. ligroin, sol. benzene.

SILICO-NITRATES. SiO₂ seems to form some compounds with N₂O₃ and basic oxides the salt 3SiO₂N₂O₃.7Ag₂O (=3Ag₄SiO₄.2AgNO₄) was obtained, in ruby-coloured prisms, by Rousseau a. Tite (C. R. 114, 294), by heating AgNO, with a little water and fragments of marble in a sealed tube at 180°-300° for several hours; heated to dull redness, it gave off N oxides, and Ag and Ag₂SiO₃ remained.

M. M. P. M.

SILICO-OXALIC ACID $H_2Si_2O_4 = {\begin{array}{c} O:Si.OH \\ O:Si.OH \\ \end{array}}$

This compound is obtained, as a white amorphous powder, by the interaction of water and Si₂Cl₆ or Si₂I₆ at 0°; the gelatinous pp. is washed with ice-cold water, dried in vacuo and then at 100° (Friedel a. Ladenburg, A. 203, 118). It is also produced by the interaction of Si.I. with

absolute alcohol. The compound is decomposed even by weak bases, with evolution of H. M. M. P. M.

SILICO PHOSPHORIC OXIDES. (Silicophosphoric acids.) SiO₂.P₂O₃ and SiO₂.P₂O₃.4H₂O. The compound SiO₂.P₂O₃.

= SiP₂O₃ is formed by dropping SiO₂, prepared by decomposing SiF, by water and drying the pp., into molten HPO, and washing with water (Hautefeuille a. Margottet, C. R. 96, 1052; v. also Skey, C. N. 16, 187). Large, hard, transparent crystals; S.G. 3·1 at 14°; melts when strongly heated to a glass-like mass. The crystals are polymorphous; they are hexagonal under 300°; at c. 300° they form leaflets resembling tridymite, between 700° and 800° they are regular octahedra, and between 800° and 1000° they assume the form of clinorhombic prisms. Water attacks the hexagonal, but not the octahedral or prismatic, crystals. Molten AgNO₂ forms Ag₂PO₄ and SiO₂ with all the forms (H. a. M., C. R. 99, 789).

The compound SiO₂.2P₂O₅.4H₂O was obtained (H. a. M., C. R. 104, 56) by one-fourth saturating H,PO,Aq with SiO,xH,O, heating the solution in a Pt dish to 125° for 7-8 hours, and drying the solid which separated. The compound is a crystalline powder; decomposed by moist air: sol. water at 0°, but decomposed by water at the ordinary temperature to H,PO Aq and gelatinous SiO, xH,O. M. M. P. SILICOPHOSPHORIC OXYCHLORIDE M. M. P. M.

SiP₂O₄Cl₄. (Silicopyrophosphorylchloride.) Prepared by heating SiCl₃.OEt, or Si(OEt), with excess of POCl₄ to 180° for 2 hours, distilling off EtCl, and SiCl, if prepared from SiCl, OEt, and heating the solid that remains to 150°-200° in a stream of dry air to remove adhering POCl₃. A white, loose, very hygroscopic, amorphous powder. Very sol. water, but with separation of SiO₂xH₂O; easily sol. alcohol, insol. ether. Decomposed very slowly below 200°, more rapidly above 200°, giving off POCl₂; at a red heat P₂O₃ comes off, and a glassy mass remains, probably consisting of SiO₂ and SiO₂·P₂O₃. Addition of excess AgNO₃Aq to solution in water (with a little alcohol to prevent separation of silical, followed by HNO.Aq note Accil tion of silica), followed by HNO, Aq, ppts. AgCl, and on filtering this off and adding NH, Aq drop by drop Ag,P₂O, is ppd. mixed with some Ag,PO, Heated to 100° with PCl, the equation SiP₂O₃Cl₂+4PCl₅ = SiCl₄+6POCl₃ is realised. The constitution of the compound is probably O.PO.CI

either
$$Si \leqslant_{O_2:PO.Cl}^{O_2:PO.Cl}$$
 or $O:Si \xrightarrow{O}$ (Stokes,

Bulletin U.S. Geolog. Survey, No. 90 [1892] 47; M. M. P. M. also in B. 24, 933).

SILICOTITANATES. Compounds of silicates and titanates are found in certain minerals; sphene, for instance (CaO.3SiO.2CaTiO.), may be called a silicotitanate. M. M. P. M.

SILICOTUNGSTATES. Compounds containing SiO₂, WO₃, and basic radicles; v. Tungsto-silicates.

SILICOVANADATES v. VANADO-SILICATES.

SILK v. Proteïds.

SILVER. Ag. At. w. 107.66. Mol. w. not known (v. infra, Properties). Melts at c. 950°;

Person (A. Ch. [8] 27, 250) gave 1000°, Daniell (T. 1830. 237) 1024°, Violle (C. R. 85, 543) 954°, Becquerel (J. 1863.) 916°, Deville (B. 12, 791) 916°. B.p. not known; Meyer (B. 12, 1428) says that Åg does not appreciably evaporate at c. 1570°. S.G. c. 10.5; Playfair a. Joule (C. S. Mem. 3, 66) gave 10.53, and 9.13 to 9.28 for molten Ag, Dumas (C. N. 37, 82) gave 10.512 for Ag heated in vacuo, Roberts-Austen gave 10.57, and 9.46 to 9.5 for liquid Ag (Pr. 23, 495); for further data v. Clarke's Table of Specific Gravities [new ed.] 14. S.H. 0°-100° = '0557 (Dulong a. Petit, A. Ch. [2] 7, 113); '0559 (Bunsen, P. 141, 1); '05722 (Louguinine, A. Ch. [5] 27, 398). C.E. '00002 between 0° and 1002 (n. Methicaen, P. 120, 50. 12. 3. 3. 100° (v. Matthiessen, P. 130, 50; Fizeau, C. R. 68, 1125); 00003721 from 0° to the m.p. (Roberts-Austen, Pr. 23, 495). T.O. 100 (that of copper = 73°6, and of Au = 53°2, Wiedermann a. Franz, A. 88, 191); heat sufficient to raise 109.6 mgm. water from 0° to 1° passes in i second through each sq. mm. of a plate of Ag 1 mm. thick, the two sides of which differ in temperature by 1° (Weber, B. B. 1880. 467). E.C. (Hg at 0°=1) 57-226 for soft Ag, 63-845 for hard Ag (Siemens, P. 110, 1); 62·12 (Benoit, C. R. 76, 382). H.C. [Ag²,O] = 5.900 (Th. 3, 381). Heat of fusion (for 108 g.) 2.275 (Person, A. Ch. [3] 24, 275); 2.67 (Pionehon, A. Ch. [6] 11, 100). S.V.S. c. 10.3. Emission spectrum gives a line 5464 in the yellow, 5200.9 in the green, and many lines in the orange, green, blue and violet (v. B. A. 1884. 442); for absorptionspectrum of Ag vapour v. Lockyer a. Roberts-Austen (Pr. 23, 344). Refraction equiv.

 $=\frac{\mu-1}{d}$. At. w. = 12.62 (Kanonnikoff, J. R. 1884.

[1] 119); 13·2 (Gladstone, Pr. 18, 49)

Occurrence.-Found native, generally alloyed with Au, Cu, &c. The chief compounds found in ores are Ag.S (frequently in combination with Cu.S, Fe,S., Sb,S., As,S., Bi,S., PbS, &c.), AgCl, AgBr, AgI, compounds of Ag with Sc, Te, As, Sb, Bi, &c. Ag is also found in small quantities in most lead ores. According to Malaguti (J. pr. 42, 422; cf. Field, D. P. J. 143, 397), traces of salts of Ag (c. 1 mgm. Ag in 100 litres) are found in sea-water. Small quantities of Ag, probably as AgCl, have been found in volcanio dust (Mallet, Pr. 47, 277). Silver has been known and used from the earliest times (for a full historical account of silver, including the derivation of the name, v. Silber in Ladenburg's Handwörterbuch der Chemie, 10, 635).

Formation.-1. By heating Ag₂S with PbO or PbSO,, SO, and a compound or alloy of Ag and Pb are formed; the Pb may be separated from this alloy by cupellation.—2. By shaking AgCl with Hg and water, HgCl and an amalgam of Ag and Hg are formed; Ag remains when the Hg is removed from this amalgam by heating.— 3. Ag is ppd. from solutions of its salts by Zn, Cu, Fe, &c.-4. AgCl is reduced to Ag by treatment with many reducing agents, such as Zn and H₂SO₄Aq, also by fusion with Na₂CO₄ and C .- 5. Most easily-oxidised metals ppt. Ag from solutions of its salts. For an account of the extraction of Ag from its ores v. Dictionary or APPLIED CHEMISTRY, vol. iii. p. 886.

Preparation.—Silver coins are dissolved in

pure dilute boiling HNO,Aq, the solution is evaporated to dryness, the residue is heated till it melts, after cooling it is dissolved in NH, Aq, after standing forty-eight hours the liquid is passed through a filter made of specially good paper, and the filtrate is diluted till it contains not more than 2 p.c. of Ag. This ammoniacal solution contains AgNO, and Cu(NO,)2; the whole of the Ag is ppd. by ammoniacal solution of (NH₁)₂SO₃ at 60°. A solution of (NII₁)₂SO₃ is prepared by saturating pure NH₃Aq with SO₄ (made by heating pure Cu with pure H.SO. diluted with $\frac{1}{2}$ to $\frac{2}{3}$ its volume of water); a measured quantity of this solution is mixed with excess of pure NH, Aq, heated to boiling, and the ammoniacal solution containing AgNO. and Cu(NO₃)₂ is run from a burette into the boiling liquid until there is the faintest trace of blue colour in the liquid above the ppd. Ag. Cuprous sulphite is formed, and this reduces the AgNO, in the ammoniacal liquid; when all the AgNOs is reduced, the blue colour of the ammoniacal copper nitrate appears. The whole of the ammoniacal solution of AgNO, and Cu(NO₂), is now mixed with the proper quantity of ammoniacal (NH₄) SO₃Aq required for complete reduction of the AgNO₃, the mixed liquids are set aside in a closed vessel for fortyeight hours, when c. 1/3 of the Ag is ppd.; the blue liquid is decanted off and heated on a water-bath to 60°-70°, whereby the whole of the Ag in solution is ppd. The two quantities of ppd. Ag are washed with ammoniacal water, by decantation, until the washings show no trace of blue colour on standing (or until BaCl₂Aq gives no trace of pp.), the Ag is kept in contact with conc. NH₃Aq for some days, and is then washed with water until every trace of NH, is removed. If it is desired to have the Ag in bars, the finely-divided metal obtained by ppn. is mixed with 5 p.c. of its weight of pure borax which has been strongly heated, and 5 p.c. pure NaNO, fused in a porcelain crucible and poured into kaolin moulds lined with a paste made of a mixture of kaolin that has been strongly heated and unignited kaolin; when cold the bars are cleaned with fine sand, then strongly heated with pure KOHAq (to remove traces of kaolin) and washed with water. The bars may be cut with a chisel of very hard steel; if this is done the pieces must be warmed for some time with pure conc. HClAq, washed with NH₃Aq, and then with water (Stas. Rech. 88 et seq.). The Ag may be freed from traces of absorbed gases by distilling it; this is done by placing the Ag in a hole in a block of strongly-heated marble; this hole communicates, by a slit in the marble, with another hole from which an opening passes upwards to the surface of the marble; another opening admits the nozzle of an O-H blowpipe, so that the flame plays on the surface of the Ag. (For flame plays on the surface of the Ag. (For details v. Stas, l.c.) Dumas (A. Ch. [5] 15, 289) found that 1 kilo. of Ag considered pure gave from 59 to 174 c.c. O when heated in a Sprengel vacuum; it was supposed by some chemists (v. Mallet, T. 1880. 1003; Clarke, Recalculations of the Atomic Weights, 262) that this result proved that Ag made by Stas' process was not quite pure; but Brauner has proved experimentally (C. J. 55, 899) that Ag prepared YOL IV,

by Stas's method described above, and distilled by the O-H flame in a block of burnt marble, gives off no O when heated in vacuo (v. also Stas, Bull. Acad. roy. Belg. [8] 18, 23; abstract in C. J. 58, 561).

Properties.—A white, very lustrous metal. Crystallises in forms in the regular system, chielly cubes, octahedra, and rhombododecahedra; these crystals are obtained by slowly cooling molten Ag, or by the electrolytic deposition of the metal; they are also sometimes found native. Finely divided Ag—as obtained, for instance, by reduction of AgCl—is a grey powder, which becomes white and lustrous when compressed with a flat iron. A thin deposit of

Ag on glass transmits bluish light.

Ag is harder than Au and softer than Cu. Ag reflects light and heat strongly; its absorptive power is very small. It is very mallcable; Ag foil has been obtained 003 mm thick. Ag is very ductile; '06 gram may be drawn to a wire 130 metres long; it is so tenacious that a cold-drawn wire of 2 mm. diameter does not break till it is loaded with 80-85 kilos (Baudrimont, A. Ch. [3] 30, 304). Ag is slightly volatile at a low-red heat in vacuo, but not at the ordinary pressure at this temperature, nor in vacuo at 410°-450° (Stas, Bull. Acad. rov. Belg. [3] 18, 23). It may be distilled, by heating, by the O-H flame, Ag placed in a block of burnt marble. Stas distilled 50 g. Ag in c. 15 mins.; part of the Ag appeared as a blue vapour during the distillation. When an alloy of Ag with a more volatile metal, such as Hg, Pb, or Sn, is heated, part of the Ag volatilises with the other metal. Molten pure Ag absorbs c. 20 times its volume of O from the air (v. Lucas, A. Ch. [2] 12, 402; Gay-Lussac, A. Ch. [2] 45, 221; Graham, P. M. [4] 32, 503; Neumann, M. 13, 40; Levol, J. pr. 57, 192); as the Ag cools it 'spits' and gives off the O it has absorbed; Dumas' experiments (A. Ch. [5] 15, 289) show that a little O is retained, but Brauner (C. J. 55, 399) has proved that no O remains if the Ag is distilled in a block of burnt marble. (For the chemical action of O on Ag v. Reactions, No. 1.) Pure Ag suffers no change when heated in air, H, or CO (van der Plaats, Mandblad voor Natuur-wetenschappen, 1886. No. 2). Molten Ag ab-sorbs P, but the whole of the P, except c. :002 p.c., separates on cooling (Warren, C. N. 56,

The at. wt. of Ag has been determined (1) by finding the ratio of Ag to Cl in AgCl (Berzelius, P. 8, 17 [1826]; Turner, T. 1829. 297 [1829]; Marignac, A. 44, 23 [1842]; ibid. Bibl. univ. Genève, 46, 354 [1843]; Maumené, A. Ch. [3] 55, 134 [1859]; Stas, Stas. Rech. 38 et seg. [1860]); (2) by finding the ratio of Ag to Br in AgBr, and of Ag to I in AgI (Marignac, l.c. 46, 360 [1843]; Stas, Stas. Nouv. R. 158 et seg. [1865]); (3) by determining the ratio of Ag to Ag.8 formed therefrom (Dumas, A. Ch. [3] 55, 147 [1859], Stas, Stas. Rech. 53 [1860]); (4) by reducing Ag.SO., to Ag (Struve, A. 80, 203 [1851]; Stas, Stas. Rech. 125 [1860]); (5) by converting Ag.SeO., into Ag (Pettersson a. Ekman, Bl. [2] 27, 205 [1876]); (6) by converting Ag.NO. (Marignac, A. 59, 289 [1843]; Stas, Stas. Rech. 50 et seg. [1860]); (7) by determining

S.H. of Ag; (6) by finding V.D. of AgCl at white heat (Biltz a. Meyer, B. 22, 725). The classical work of Stas has placed the value for the at. wt. on a very sure foundation.

Ramsay (C. J. 55, 521) measured the depression of the vapour-pressure of Hg by dissolving Ag therein; assuming that the mol. w. of liquid Hg is 200, and that equal volumes of dilute solutions of metals in Hg contain equal numbers of molecules, the results led to the conclusion that the mol. w. of Ag is the same as the at. wt.

AgCl is the only compound of Ag the vapourdensity of which has been determined; the value found shows that the atom of Ag is monovalent in the gaseous molecule AgCl.

Ag is fairly closely related chemically to Cu and Au (v. Copper group of Elements, vol. ii.

p. 250).

Allotropic forms of silver. According to Schneider (B. 25, 1281, 1440), an aqueous solution of Ag, containing c. 20 g. Ag per litre, is obtained by mixing 150 g. FeSO, 7aq in 500 c.c. water and 280 g. Na citrate in 700 c.c. water, pouring the mixture into 500 c.c. of 10 p.c. AgNO, Aq (it is best to divide the mixture into five parts, as small quantities are more easily dealt with), removing liquid from ppd. Ag after half an hour (by a pipette), filtering through a good filter under decreased pressure, and dissolving the ppd. Ag in as little water as possible; by adding absolute alcohol, and filtering, after some days, with help of a good waterpump, colloidal Ag containing from '3 to '5 p.c. of Fe salts is obtained. A very little HClAq ppts. Ag with a little AgCl and Ag.Cl (?) from solution of colloidal Ag. Carey Lea has carried out a series of researches on the properties of Ag ppd. from solutions of its salts by ferrous citrate, ferrous tartrate, and dextrin in presence of alkali (Am. S. [3] 37, 476; 38, 47, 129, 237; 41, 179, 259; P. M. [5] 31, 238, 320, 497; 32, 937). The pps. of Ag show almost every shade of colour, such as blue, red, green, purple, golden; some of the pps. are soluble in water, and some are not; most of the pps. are very sensitive to light, but they vary much in this respect; some of the pps. yield ordinary Ag when heated; ordinary Ag is also ppd. from solutions of soluble colloidal Ag by a little very dilute HClAq. In no case does any so called allotropic Ag seem to have been obtained quite free from organic compounds; the percentage of Ag in the pps. varied from c. 90 to c. 98. For accounts of the properties of the various coloured pps. the memoirs of Carey Lea must be consulted; v. also Schneider, B. 24, 3370; Barus a. Schneider, Z. P. C. 8, 278; Prange, R. T. C. 9, 121; Muthmann, P. 20, 983. B. a. S. determined many of the physical properties of a solution of colloidal Ag, and concluded that the colloidal variety consists of extremely minute particles of ordinary Ag that remain suspended in the liquid for a considerable time.

Reactions and Combinations.—1. According to Debray (C. R. 66, 735), Ag is partially oxidised by very strongly heating in the O-H flame, using excess of oxygen. According to Le Chatelier (Bl. [2] 48, 342) pure ppd. Ag is oxidised by heating in oxygen at 300° under 15 atmos. pressure; after 50 p.c. of the Ag was

oxidised the change stopped .- 2. Ozonised oxygen acts on moist, finely-divided Ag at the ordinary temperature, forming a peroxide (v. Silver Peroxide, p. 471).—3. Ag combines easily with chlorine, bromine, iodine, and sulphur (v. SILVER CHLORIDE &c.); also, by heating, with selenion, arsenic, and phosphorus (v. SILVER SELENIDE &c.).-4. Finely-divided Ag'is said to dissolve, with oxidation, in ammonia solution in presence of air (Carey Lea, Zcit. filr anorg. Chem. 3, 180).—5. Ag reacts with steam at a white heat, absorbing O while H is given off.— 6. Finely-divided Ag is oxidised by hydrogen peroxide (Berthelot, A. Ch. [5] 21, 164).—
7. Finely-divided Ag is said to be oxidised by heating with oxides and salts that readily give up oxygen-e.g. MnO₂, Pb₃O₄, Pb(NO₃)₂, &c.-8. Hydrogen sulphide forms Ag.S. Alkali sulphides also produce Ag2S .- 9. Molten sodium chloride forms AgCl, some Na vapour being given off; solution of sodium chloride, as also of potassium or ammonium chloride, dissolves some Ag as AgCl.-10. Potassium iodide solution, in air, forms soluble AgI.KI.-11. Hot solution of potassium cyanide dissolves Ag, forming AgK(GN)₂ (v. Christomanos, Fr. 7, 301).—12. Fusion with silicates, such as glass, forms Ag₂O, which dissolves in the molten silicate .- 13. Ag dissolves in solution of ferric sulphate on warming; as the solution cools the Ag, SO, is again decomposed, with formation of Fe₂(SO₄)₃ and ppn. of finely-divided Ag.—14. A compound of Ag and Si is said to be formed by strongly heating Ag with potassium silico-fluoride and potassium (Warren, C. N. 60, 5).— 15. Ag dissolves in moderately dilute nitric acid, forming AgNO₃, and giving off N oxides; the gaseous products are N₂O and NO, according to Montemartini (G. 22, 384, 397, 426).—16. Conc. hydrobromic and hydriodic acids dissolve Ag on warming, with evolution of H; the dissolved AgBr or AgI is ppd. on dilution.—17. Hot conc. sulphuric acid dissolves Ag, giving off SO₂; if a little Fe2(SO4)3 solution is added the Ag goes into solution without heating. Very finelydivided Ag, obtained by reduction of Ag saits by milk-sugar and alkali, is dissolved by very dilute H₂SO,Aq (Carcy Lea, Zeit. für anorg. Chem. 3, 180). Friedheim (B. 19, 2554; 20, 307) says that Ag dissolves in dilute H2SO, Aq containing KMnO₄Aq.—18. Chromic acid (i.e. solution of CrO₃ in water) produces red Ag₂CrO₄; HNO₃Aq, S.G. 1·2, in which K₂CrO₄ is dissolved, gives a red deposit on the surface of Ag; this test is used to distinguish Ag from other white metals, such as Sn.-19. Ag in pieces is scarcely acted on by hydrochloric acid, even when hot and conc.; very finelydivided Ag is said to form a little AgCl, with evolution of H. Hydrofluoric acid is without reaction. - 20. Ag is not acted on by molten alkalis or alkaline carbonates; hence KOH, &c., may be fused in dishes of Ag.-21. Ag alloys with many metals (v. Silver, alloys or).

Silver, alloys of. Ag forms alloys with many metals. They are generally formed by heating the metals together; in a few cases—e.g. alloy with Ba or Mn—they are formed by heating Ag with metallic cyides and C.

heating Ag with metallic oxides and C.

With aluminium. An alloy of 100 parts
Al with 5 parts Ag is harder and more easily

4.4

the properties of Al: it is used for making the pans, &c., of balances. Hirzel (J. 1858. 137) obtained alloys corresponding in composition with the formulæ Ag,Al, Ag,Al, and AgAl (v. also Tissier, C. R. 43, 885; 52, 931; Debray, C. R. 43, 925).

With antimony, and with arsenic; v. SILVER

ANTIMONIDE and ARSENIDE, infra.

With copper. Ag becomes harder, more elastic, more capable of being polished, and more slowly worn away when alloyed with Cu without losing much in malleability and ductility. Alloys with less than 50 p.c. Cu are white, with more than 50 p.c. Cu the colour becomes reddish. The S.G. of a Ag-Cu alloy is rather smaller than the mean of those of the constituent elements (v. Karmarsch, D. P. J. 108, 278). The composition of these alloys is rarely identical throughout a mass (v. Levol, A. Ch. [3] 36, 193). Alloys of Ag and Cu are used for making silver vessels and ornaments, and for coinage; the standard silver coinage alloy of the United Kingdom contains 925 parts Ag and 75 parts Cu per 1,000.

With mercury. The amalgams of Ag are formed (1) by the action of Hg on AgNO₃Aq, (2) by the action of finely-divided Ag on HgCl, Aq, (3) by dissolving Ag in Hg. The compositions of many of these amalgams can be represented by formulæ, but it is very doubtful whether any of them are definite compounds. For accounts of these amalgams v. Campani, J. 1870. 373; Joule, C. J. [2] 1, 378; Crookewitt, J. 1847-48. 393; Malaguti a. Durocher, Ann. M. 17, 336;

Gay-Lussac, A. Ch. 58, 218.

Alloys of Ag with the following metals have been described :- Ba (Clarke, G. A. 62, 373; Lampadius, S. 15, 146); Cd (Wood, C. N. 6, 135); Au (G. Rose, P. 23, 181; Levol, A. Ch. [3] 15, 55; 27, 310); Ir; Fe; Pb (Levol, A. Ch. [3] 39, 173); Mg; Mo; Ni; Pd (Graham, J. 1868. 144); Pt; K; Rh; Na; Sn; Zn (v. Wright a. Thompson, Pr. 48, 25).

Silver, antimonide of. The mineral dyskrasite has approximately the composition Ag, Sb; when heated to dull redness in H, the compound Ag, Sb is said to remain (von Bonsdorff, S. 34, 225). The compound Ag, Sb is also obtained by ppg. AgNO, Aq by Sb hydride; using conc. AgNO, Aq the compound Ag, Sb.3AgNO, was formed (Poleck a. Thümmel, B. 16, 2435)

Silver, arsenide of. No definite compound of Ag and As has been obtained. By heating Ag powder with As about 16 p.c. of As is absorbed by the Ag to form a grey, brittle solid By passing As hydride into conc. (Gehlen). AgNO, Aq the compound Ag, As. 3 AgNO, was obtained (P. a. T., l.c.).

Silver, bromide of, AgBr. (Argentic bromide.) Formula probably molecular, from analogy of AgCl. Occurs native in Chili and Mexico.

Preparation. - HBrAq or alkali bromide solution is added to AgNO, Aq till ppn. is complete; the pp. is washed with water in the dark and dried.

Properties.-A pale-yellow solid; melts at c. 434° (Carnelley, C. J. 29, 489). S.G. 6.245 at

polished than Al, but otherwise has most of For effects of heat on AgBr v. Rodwell (Pr. 25. 280). Obtained in octahedra by crystallising from HBrAq. Solubility of AgBr dried at 100° in NH Aq S.G. 986, = 051 (Pohl, J. pr. 82, 52). Granular AgBr is slightly sol. water above 50° flocculent AgBr is slightly sol. water above 33° (Stas, A. Ch. [5] 3, 289). Sol. hot Hg(NO₂), Aq; AgBr crystallises out on cooling (Debray, C. R. 70, 995). Sol. solutions of alkali bromides. H.F. [Ag,Br] = 22,700 (Th. 3, 381). According to Berthelot (Bl. [2] 39, 19), the reaction [Ag,Br] has the value 23,700 when crystalline AgBr is formed, and the value 20,000 when the AgBr is amorphous (in both cases using liquid Br). B. also says that in the formation of AuBr by add. ing KBrAq to AgNO3Aq 20,700 cals. are produced, and that when AgNO, Aq is added to KBrAq only 17,600 cals. are produced at first, but that temperature then rises until 20,600 cals, are evolved; B. thinks that two forms of AgBr are formed, one more stable than the other. Vogel (B. 16, 1160) distinguishes two modifications of AgBr, one ppd. from aqueous solutions and very sensitive to blue rays, the other ppd. from solutions in absolute alcohol and sensitive to the violet rays. Stas (A. Ch. [5] 3, 289) distinguishes six forms of AgBr:—(1) flocculent, white, by adding dilute alkali bromide solution to excess of cold AgNO₃Aq; (2) flocculent, yellow, by using excess of bromide as pptant.; (3) powdery, white, by shaking (1) or (2) with water; (4) intense yellow, by heating (4); (5) granular, white-yellow, by pouring the flocculent or powdery variety, shaken with water, into boiling water, also by adding very dilute NH BrAq to boiling AgNO₃Aq (1:1000); (6) pure yellow, crystalline variety.

Reactions and Combinations. — 1. AgBr darkens rapidly when exposed to sunlight. Carey Lea says that the dark product of the action of light on AgBr reacts with HNO,Aq to re-form AgBr, and Ag which dissolves in the acid (Am. S. [3] 15, 189). The action of light on the Ag haloids is treated more fully under Silver chloride (q. v.).-2. Heated in chlorine, AgCl and Br are produced. - 3. Dissolves slowly in hot silver nitrate solution; the salt AgBr.AgNO, separates on cooling (Risse, A. 111, 43; Riche, A. 111, 39).-4. Combines with silver chloride and iodide to form compounds AgaBrbIcCld (v. SILVER IODOBROMOCHLORIDES, p. 470).

AgBr resembles AgCl in most of its reactions; NH, is not absorbed by dry AgBr (Rammelsberg, P. 55, 248).

Silver, bromo-iodochlorides of, v. Silver IODOBROMOCHLORIDES (p. 470).

Silver, carbides of. Gay-Lussac noticed that Ag absorbed c. 3 p.c. C when heated with lampblack (A. Ch. [2] 58, 222); Ag,C requires 2.7 p.c. C. A yellow powder, approximately agreeing with the composition Ag.C. was obtained by Gerhardt and Cahours (A. Ch. [3] 1, 76) by heating Ag cuminate; the same compound was probably produced by Liebig by heating AgCN (A. 38, 21). By heating an aqueous solution of Ag pyrotartrate, filtering from the brown pp. produced, and boiling the pp., Berzelius obtained 0°, 5·595 at m.p. (Rodwell, Pr. 31, 291). S.H. a dark-brown, metal-like pp., probably AgC (P. (15° to 98°) ·07891 (Regnault, A. Ch. [3] 1, 129). 36, 28; of. Regnault, A. 19, 153).

Silver, chlorides of. The isolation of a chloride | 1 of Ag containing less Cl than AgCl is not yet certain. Cl is given off when AgCl darkens in sunlight, but whether the darkened product is a chloride or an oxychloride is not finally determined (v. Action of light on silver chloride,

SILVER SUBCHLORIDE ? Ag2Cl. chloride.) According to Güntz (C. R. 112, 861), Ag₂Cl is formed by passing dry HCl over Ag₂F (v. Silver subfluoride, p. 469) as long as darkening occurs and the solid continues to gain in weight. The compound is also said to be formed by passing vapour of CCl, SiCl, or PCl, over dry Ag.F. A subchloride is formed, according to von Bibra (J. pr. [2] 12, 55), by digesting with conc. HClAq the product of the reduction of Ag citrate by H at 100°; after drying, the black solid is said to have the composition Ag, Cl3, and with NH_3 Aq to give Ag and $AgCl.3NH_3$. bury (Am. 8, 196) failed to obtain any subchloride by this method; he also found that the reduction of Ag citrate by H at 100° does not yield any definite compound, but probably a mixture of unchanged citrate and Ag.

SILVER CHLORIDE AgCl. (Argentic chloride.) Mol. w. 143.03. V.D. 80 at c. 1700° (Biltz a. Meyer, B. 22, 725). Melts at c. 457° (Carnelley, C. J. 29, 489). S.G. at 0°=5505; at m.p. = 4*919 (Rodwell, Pr. 31, 291). S.H. (13° to 98°) .09109 (Regnault, A. Ch. [3] 1, 129). For expansion of AgCl by heat v. Rodwell (Pr. 25, 280). H.F. [Ag,Cl] = 22,700 (Th. 3, 381); 29,200 (Berthelot, Bl. [2] 39, 19). For solubilities in various liquids v. Properties.

Occurrence. - Native, as hornsilver, Siberia, Mexico, Peru, the Harz, Alsace, &c.

Preparation .- 1. By adding dilute HClAq, or solution of a chloride, to solution of any salt of Ag except Ag2S,O3, washing the white curdy pp., drying, and heating to incipient fusion. Obtained in octahedral crystals by dissolving in large quantity of conc. HClAq and evaporating.— 2. By heating Ag to redness in a stream of Cl or HCl gas.-3. By fusing NaCl with finely divided Ag, washing, and drying.-4. Very slowly by the action of HClAq on Ag in the presence of air.

Properties .- A white solid. According to Cooke (Am. S. [3] 21, 220) AgCl is very slightly sol. cold water, and very distinctly sol. boiling water; he found that 1.4561 g. AgCl washed with 66 litres boiling water lost 2241 g. = 15.39 p.c.; the solvent action was entirely prevented by the addition of 05 g. AgNO, per litre of water. Stas (C. R. 73, 998) distinguished four forms of AgCl: (1) gelatinous; (2) curdy, flocculent; (3) powdery; (4) granular, crystalline, or fused. The curdy, flocculent form is the most sol. in water; it is formed by ppg. cold dilute AgNO Aq by a chloride solution; on shaking it changes to the less sol. powdery variety. The granular, crystalline, or fused form is insol. cold water (10 million parts cold water dissolve 1 part) but it begins to dissolve at 30° (cf. Berthelot, A. Ch. [5] 29, 241, for the heats of solution in KCNAq of different preparations of AgCl). AgCl is sol. conc. HClAq and in saturated solutions of various metallic chlorides; Vogel (C. C. 5, 578) gives the following table :-

100 a	e. cold HClAq S.G. 1.165	dissolve	-298	6	78QI

One part AgCl dissolves in 50,000 parts boiling conc. HNO, Aq (Thorpe, C. N. 25, 198). NH, Aq dissolves AgCl; 1 litre NH, Aq S.G. 924 dissolves 69.5 g. freshly ppd. AgCl, according to Millon and Comaille (C. R. 56, 309). AgCl crystallises from solutions in NH3Aq, on evaporation; explosive silver is obtained from boiling solutions (v. SILVER NITRIDES, p. 470). According to Terreil (Bl. [2] 51, 598), crystals of AgCl.2NH, separate from a hot solution of AgCl in NH,Aq; these crystals lose NH, in the air. AgCl dissolves easily in Na,S2O3Aq, forming Ag2Na,(S2O3)3Aq; AgCl also dissolves readily in KCNAq forming AgK(CN), and in NH, HSO, Aq forming double Ag-NH, sulphites (v. Svensson, B. 4, 714). A hot solution of AgNO, Aq dissolves AgCl; Risse says that a double compound of AgNO, and AgCl separates on cooling (A. 111, 39), but Debray asserts that simple solution occurs (C. R. 70, 995). Hg(NO₃), Aq also dissolves AgCl; Wackenroder (A. 91, 317) and Field $(\tilde{J}.~1857.~255)$ say that AgCl separates on cooling a hot saturated solution; Stas (A. Ch. [5] 3, 180) found that a little AgNO, is formed.

Reactions.—1. AgCl is reduced to Ag by many metals, e.g. Zn or Fe, in presence of dilute acid; Cu reduces AgCl in presence of NH₂Aq, with formation of Ag and CuO.H₂O.— 2. Heated in hydrogen, or with carbon, or with several organic compounds, AgCl is reduced to Ag.—3. Solution of hydriodic acid forms AgI and HClAq.—4. Caustic alkali solutions pro-

duce Ag₂O.

Action of light on silver chloride. AgCl darkens when exposed to sunlight in ordinary air. During the darkening Cl is given off (Scheele; von Bibra, J. pr. 122, 39; Hitchcock, Am. 11, 474; Béchamp, Bl. [3] 6, 836; Richardson, C. J. 59, 536; Baker, C. J. 61, 728). Only a small portion of the AgCl is changed to the dark compound (v. R., l.c.; B., l.c., got 09 g. of the dark body from 51 g. AgCl). AgCl does not darken in thoroughly dried oxygen (B., l.c.; nor in dried air according to Carey Lea, Zeit. fur anorg. Chem. 3, 184). AgCl does not darken in vacuo, when thoroughly dry (Abney; B., l.c.). Carey Lea (l.c.) found that AgCl darkened under dry petroleum; Baker noticed darkening under benzene in absence of air, and he showed that the dark substance was Ag. B. (l.c.) noticed darkening, with formation of Ag, under CCl,, but he proved that if the CCl, contained no trace of free Cl darkening did not occur. For the influence of HCl and chlorides in water upon the rate of darkening of AgCl in the water v. Richardson (l.c.). The dark substance was supposed by some to be a subchloride, but Baker

has shown that it contains O (Hodgkinson had formerly arrived at this conclusion; v. Meldola's Chemistry of Photography [1889], p. 856). B. kept pure AgCl, dried at 150°, in sunshine, in a current of air freed from CO. and dried by H2SO4, until it darkened; he measured the O obtained from the darkened product, by decomposing by Cl, and also determined the Ag and Cl; the results agreed approximately with the formula Ag, OCl; the atomic ratio of Ag to Cl found in various experiments was almost exactly 2:1, and of Ag to O was nearly 5:2; the darkened product dissolved in conc. KClAq, on dilution AgCl was ppd. and the solution had a slightly alkaline reaction, as would be expected if an oxychloride were present in the dark-coloured substance. B. also found that a little H2O was obtained by heating the dark substance in dry H; Richardson (C. J. 59, 536) failed to obtain any water by treating darkened AgCl in this way; R. also failed to get O from the darkened AgCl by heating it to the m.p. in connection with a Sprengel pump. B. (l.c.) found that the darkcoloured product became white when left in the dark for some days, and that a small quantity of O was absorbed during this change; he, therefore, concludes that two oxychlorides of Ag are formed, one of which is dark-coloured and absorbs a little O to form another, white, oxychloride. Carey Lea (Am. S. [3] 38, 356) thinks that the darkening action of light on AgCl is preceded by the formation of what he calls a photochloride. The photochloride is supposed to contain less Cl than the normal chloride; and probably to be a compound of AgCl with a subchloride or oxychloride; it is extremely sensitive to the action of light, and undergoes many changes of colour when exposed to light (Am. S. [3] 33, 349, 480, 489; 34, 33; and full abstract in C. J. 54, 1). For the application of the effects of light on AgCl to photography v. Photography CHEMISTRY, this vol. p. 154; and Photography, in Dictionary of Applied Chemistry, vol. iii.

Combinations .- 1. With several metallic chlorides, especially the alkaline chlorides; generally forming compounds of the type AgCl.MCl. Wells and Wheeler (Am. S. [3] 44, 155) obtained the compound AgCl.2CsCl.— 2. With ammonia gas. According to H. Rose (P. 20, 157), 2AgCl.3NH, is formed. Isambert (C. R. 64, 1259; v. also Horstmann, B. 9, 749) studied the vapour-pressures of the NH, given off, and concluded that two compounds are formed when NH, is absorbed by AgCl-viz. 2AgCl.3NH, and AgCl.3NH, (v. curves given in Drssocarron, vol. ii. p. 397). Bodländer (Z. P.C. 9, 730) measured the reduction of the freezingpoint of water produced by the compound 2AgCl.3NH₂; as this reduction was much larger than the normal, he concluded that the compound is dissociated in aqueous solution; a similar conclusion was come to by measuring the electrical conductivities of aqueous solutions. The dissociation cannot have been into NH, and AgCl, says B., else AgCl would have separated out; hence the dissociation must be electrolytic, and the solution must contain Ag and Ol as free ions. This conclusion was confirmed by finding that PbAc,Aq ppd. PbCl, from 2AgCl.3NH, in NH,Aq, KIAq ppd. AgI, and (NH,),SAq ppd. Ag₂S; confirmatory evidence

was also found in the fact that addition of NH₄Cl or AgNO₃ reduced the solubility in water of 2AgCl.3NH₃, in keeping with the law regarding the effect on the solubility of an electrolyte of the presence of one of its ions. B. concludes that 2AgCl.3NH₃ is a definite compound, which is electrolytically dissociated in aqueous solution.—3. With silver iodide and bromide; v. SILVER IODORROMOCHLORIDES, p. 470.

Silver, chloro-iodobromides of; v. Silver iodobromochlorides, p. 470.

Silver, cyanide of; v. vol. ii. p. 346.

Silver, ferricyanide of; v. vol. ii. p. 340.

Silver, ferrocyanide of; v. vol. ii. p. 837.

Silver, fluorides of. Two fluorides of Ag

Silver, fluorides of. Two fluorides of Ag probably exist, Ag_2F and AgF, although there is still some doubt as to the isolation of the first of these.

SILVER SUBFLUGRIDE (? Ag.F). (Argentous fluoride.) By electrolysing saturated AgFAq, using Ag electrodes, and a current so strong that the liquid became hot, Güntz (C. R. 110, 1337) noticed the separation of brass-coloured crystalline plates at the negative pole (if a weaker current was used, Ag was deposited). Treatment of these crystals with water gave AgFAq and Ag, the ratio of Ag separating to Ag going into solution being practically unity; hence G. gives the formula Ag.F to the yellow crystals. G. says that the same compound is obtained by heating finely-divided Ag with AgFAq in a sealed tube to nearly 90°. Ag.F does not change in dry air; it decomposes slowly in moist air, and rapidly in water. Heated in dry HCl, CCl., PCl., &c., Ag.Cl is said to be formed (G., C. R. 112, 861).

SILVER FLUORIDE AgF. (Argentic fluoride.) Formula probably molecular, from analogy of AgCl. Prepared by dissolving Ag.CO, that has been freshly ppd. and well washed, in HFAq, evaporating to dryness in a Pt dish, with constant stirring, dissolving the black residue in water, filtering, and evaporating in vacuo over H2SO,, in the dark (Moissan, Bl. [3] 5, 456; cf. Güntz, A. Ch. [6] 3, 42). A yellow, transparent, elastic solid; sol. water; melts at c. 435° (M., l.c.). S.G. 5.852 at 15.5° (Gore, Pr. 18, 157). Fremy (A. Ch. [3] 47, 39) obtained large colourless prisms, to which he gave the formula AgF. 2aq, by evaporating a solution of Ag₂CO₂ or Ag,O in HFAq; these crystals lost 2aq in vacuo, but some oxyfluoride was always formed (cf. Marignac, Ann. M. [5] 15, 270). Heated in air, AgF is decomposed, by the moisture present, to Ag, O, and HF, according to Gore (i.c.). AgF interacts violently with POCl₃, PCl₃, SiCl₄, and BCl₃, giving AgCl and fluoride of P, Si, or B (Moissan, *l.c.*). Molten AgF attacks vessels of Ag or Pt. The dry salt is said to absorb c. 800 times its volume of NH, (Gore, l.c.). Heating with I produces AgI and IF, (Gore, Pr. 30, 70; where a few other reactions of compounds with AgF are given).

Silver, fulminating; v. Silver nitrides, p. 470; Silver fulminate (q. v., vol. il. p. 317) is sometimes called fulminating silver.

Silver, hydroxides of; v. Silver oxides and hydrated oxides, p. 470.

Silver, iodides of. The isolation of an iodide other than AgI is very doubtful.

SILVER SUBIODIDE (? Ag.I). Güntz (C. R. 112, 861) states that this compound is formed by the interaction of HI and Ag.F; but no

analyses are given.
Silven lodide Agl. (Argentic iodide.) Formula probably molecular, from analogy of AgCl. Melts at c. 530° (Carnelley, C. J. 29, 489); at 527° (Rodwell, Pr. 25, 280). S.G. at 489); at 527° = 5·522; maximum density at 142° (R., l.c.). V.D. said to be 214 (Dewar a. Scott, B. A. 1881. 597). S.H. (15° to 98°) ·06159 (Regnault, A. Ch. [3] 1, 129; v. also Bellati a. Romanese, Pr. 34, 104). H.F. [Ag,I] = 13,800 (Th. 3, 381); 14,300 for crystalline AgI (Berthelot, Bl. [2] 39, 18).

Occurrence .- As iodite in Peru, Mexico, the Harz, Spain, &c.; forms hexagonal tablets; also in combination with AgBr as iodobromite

in small quantities in Nassau.

Preparation .- 1. By adding HIAq, or solution of an iodide, to AgNO₃Aq, washing, and drying.—2. By the interaction of finely-divided Ag with HIAg, H is evolved at ordinary temperatures and AgI formed; a solution saturated by heating HMq with Ag deposits crystals of AgI.xHI on cooling (v. infra, Combinations, No. 2), and the liquid decanted from these deposits hexagonal crystals of AgI on standing in air .-8. Crystals of AgI are also obtained by boiling saturated AgNO₃Aq with HgL, and allowing to cool (Field, J. 1857, 255).—4. The interaction of a mixture of HClAq and HIAq with Ag produces only AgI, according to Deville (A. 101,

Properties.—As obtained by adding alkali lodide to excess of AgNO3Aq, AgI is a curdy pp., yellow, with a slight orange tint; by adding AgNO.Aq to excess of alkali iodide, a pure yellow, powdery pp. of AgI is formed; the former pp. is sensitive to light, the latter, after washing in the dark, is not discoloured by light. AgI melts to a yellow liquid, which becomes red and then dark-red as temperature rises; the liquid solidifies to a yellow, horny, crystalline mass.. Rodwell (Pr. 25, 280) found that AgI contracted considerably at the moment of solidification; regular contraction then took place to 142° whereat there was sudden and considerable expansion accompanied by change from the amorphous to the crystalline form; this was followed, as temperature fell, by slight expansion (for measurements v. R., l.c.). AgI exists in two forms: above 142° up to the m.p. it is yellow, transparent, and flexible; below 142° it is pale green, crystalline, opaque, and brittle (R., I.c.). AgI is nearly insol. NH3Aq; according to Martini (S. 56, 153) 1 part AgI requires 2560 parts NH, Aq, S.G. 96, for solution. AgI dissolves in Na,S₂O,Aq, in KCNAq, and in NaClAq; it dissolves readily in hot Hg(NO₄),Aq, and crystallises therefrom on cooling (v. also Combinations).

Reactions .- 1. Heated in chlorine, AgCl is formed .- 2. Reduced by contact with metals, such as Zn or Fe, in presence of acids. Most of the reactions of AgI closely resemble those of AgCl.

Combinations .- 1. Dry AgI absorbs ammonia; Rammelsberg (P. 48, 170) says that 2AgI.NH, is formed (for dissociation-pressures of this compound v. Isambert, C. R. 64, 1259). By heating

AgI with excess of NH, Aq in a sealed tube at 100°, Terreil obtained crystals of AgI.2NH, (Bl. [2] 41, 598).—2. AgI dissolves in hot conq. hydriodic acid solution; the liquid deposits large, colourless, unstable crystals of AgI.HI (?) (Deville, C. R. 42, 895); Berthelot obtained transparent crystals of 3AgI.HI.7H₂O (A. Ch. [5] 23, 89).—3. According to Preuss (A. 29, 328) a solution of AgI in a hot solution of mercuric nitrate deposits crystals of 4AgI.2Hg(NO2) aq on cooling.-4. AgI dissolves in silver nitrate solution containing more than 3 p.c. AgNO. (Vogel); water re-ppts. AgI. For accounts of different compounds obtained v. Kremers (J. pr. 71, 54), Stürenberg (Ar. Ph. [2] 143, 112), Weltzien (A. 95, 127), Riche (A. 111, 39), Risse (A. 111, 43). AgI also combines with silver nitrate and lead nitrate, and with antimonide, arsenide, phosphide, and sulphide of silver (v. Poleck a. Thümmel, Ar. Ph. [3] 22, 1).—5. With alkali iodides and alkaline earth iodides (v. Boullay, A. Ch. [2] 34, 377; Berthelot, Bl. [2] 39, 24; Johnson, C. N. 37, 110; Maxwell Simpson, Pr. 27, 120).

Silver, iodobromochlorides of. Rodwell (Pr 25, 292) prepared various compounds of AgI AgBr, and AgCl by melting the constituents together. R. studied especially the effects of heat on the S.G., change of volume, and m.p. of these bodies. The formula xAgI.yAgBr.zAgCl expresses the composition of the compounds examined; x varied from 1 to 4, y was always 1,

and z varied from 1 to 2.

Silver, nitrides of. Raschig (A. 233, 93) has shown that the explosive substance first prepared by Borthollet, by the action of conc. cold NH₃Aq on Ag₂O, and supposed by B. to be a compound of Ag₂O and NH₃, is a nitride of Ag, Ag, N, mixed with finely-divided Ag. Ag, N is best prepared by allowing a conc. solution of Ag₂O in NH₃Aq to stand in air, or by adding alcohol. Ag₃N dissolves in KCNAq,

forming AgCN, KHOAq, and NH₃.

The Ag salt of HN₃ may be called silver nitride; v. Hydrazoro Acid, vol. iii. p. 559. Silver, nitroprusside of, v. vol. ii. p. 341.

Silver, oxides and hydrated oxides of. Only one oxide of Ag has been certainly isolated; the existence of any hydrated oxide is doubtful.

SILVER OXIDE Ag,O. (Argentic oxide.) Mol. w. not known.

Formation.-1. By heating Ag much above the temperature of volatilisation in the O-H flame, using excess of O (Debray, C. R. 66, 735).-2. By passing an electric current through KNO₃Aq, using a plate of Ag as positive electrode (Wöhler, A. 146, 264).—3. By boiling freshlyppd. AgCl with KOHAq, S.G. 1·25 to 1·3 (Mohr, A. 66, 65).

Preparation .- KOHAq is added in slight excess to AgNO₃Aq, the pp. is thoroughly washed with hot water, best in air freed from CO₂, and

dried at c. 80°.

Properties.-A black powder (brownish when ppd.), with an unpleasant, metallic taste. S.G. 7.52 (Schröder, B. 9, 1888); 7.15 (Playfair a. Joule, C. S. Mem. 3, 84): 7.25 (Boullay, A. Ch. [2] 43, 266). H.F. [Ag²,O] = 5,900 (Th. 3, 381). Slightly sol. water; 1 part dissolves in 3,000 parts water according to Bineau (C. R. 41, 509). but according to Abl in 96 parts water at 18.50

(Oester. Zett. f. Pharm. 8, 201 [1884]). Sol. NH.Aq (for so-called explosive silver, formed by dissolving in conc. NH, Aq, v. SILVER NITRIDES. p. 470). Also sol. aqueous solutions of alkali thiosulphates, chlorides, and cyanides. Sol. aqueous MeNH₂ and EtNH₂ (Wurtz, A. Ch. [3] 80, 453). Moist Ag₂O absorbs CO₂ from the air, forming Ag₂CO₃, and reacts with many salts like the alkalis (v. Reactions). Ag₂O is decomposed to Ag and O by heat (v. Reactions).

Reactions and Combinations. - 1. Decomposed to Ag and O by heat; Carnelley and Walker (C. J. 53, 79) say that O begins to come off at c. 100°, rapid decomposition occurs at c. 270°, and reduction is complete at 300'-340° (v. also H. Rose, P. 85, 317; Joulin, Bl. [2] 19, 349; cf. Hydrated Silver oxide, infra).— 2. Antimony sulphide, arsenic sulphide, finely-powdered sulphur and selenion, amorphous phosphorus, and some organic compounds, are ignited by rubbing with Ag₂O (Böttger, J. 1863. 284).— 3. Reduced to Ag by heating to 100° in hydrogen (Wöhler, A. 30, 4).-4. Finely-divided Ag₂O under water is reduced to Ag by cadmium, copper, tin, and zinc (not reduced by Fe or Hg) (Fischer, P. 10, 605).-5. AgI and HIO, are formed by the reaction of iodine with Ag2O suspended in water (Naquet, Bl. 1860, 123); with chlorine the products are AgCl, HClOAq, AgClO, and AgClO, (Stas). - 6. Moist Ag2O decomposes many metallic salts in solution, ppg. metallic hydroxides, e.g. salts of Bi, Cr, Co, Cu, Fe, Hg (v. H. Rose, B. 1857. 245).—7. The moist oxide removes halogens from many halogencontaining organic compounds, replacing the halogen by OH (e.g. 2NMe,I+Ag,O.H,O halogen by OH (e.g. $2NMe_1I + Ag_2O.H_2O$ = $2NMe_4OH + 2AgI).$ —8. Ag_2O reacts with acids as a decidedly basic oxide, forming salts Ag2X, where $X = SO_4$, $2NO_{31}$ &c. -9. A little $AgNO_2$ is said to be formed when nitric oxide is passed into water with Ag.O suspended therein (Sabatier a. Senderens, C. R. 114, 1476).—10. Ag.O combines with lead monoxide; by allowing a mixture of PbO.xH2O and freshly ppd. Ag2O to stand in contact with NaOHAq, a compound was obtained, probably 2Ag₂O.PbO (E. Aston, C. J. 59, 1093).

HYDRATED SHIVER OXIDE (? AgOH). According to H. Rose (P. 85, 904), no compound of Ag₂O and H₂O exists. By ppg. an alcoholic solution of AgNO₃ by KOHAq at -40°, Bruce obtained a white flocculent pp. which he supposed to be a hydroxide of Ag (no analyses are given); the pp. darkened on heating, forming Ag₂O and H₂O according to B. (C. N. 50, 208). Carey Lea (Am. S. 1892, 249) found that ppd. Ag₂O retained some water after drying at 100° for 40 hours, and that all water was removed at 160°-165° but some O went off also. Carnelley and Walker (C. J. 53, 79) say that the product of drying ppd. silver oxide in air for 6 months had the composition AgOH, and that this was scarcely decomposed at 100°, but that above this temperature it gave off water and a little O, and was gradually changed to Ag.O mixed with a little Ag. Some reactions of moist Ag2O point to the existence of such a compound as AgOH (v. SILVER OXIDE, Reactions, Nos. 6 and 7).

OXIDE OF SILVER WITH LESS OXYGEN THAN Ag.O. (Silver suboxide.) Many experiments are recorded on the interactions of reducing

agents and Ag salts whereby salts of a lower oxide than Ag₂O were supposed to be formed, and the corresponding oxide was supposed to be ppd. from these salts by alkali. Wohler (4.30, 1) reduced Ag citrate by heating in H; W. a. Rautenberg reduced ammoniacal solutions of chromate, molybdate, and tungstate of Ag (A. 114, 119); W. reduced arsenate and phosphate of Ag by FeSO, (A. 146, 263); H. Rose reduced AgNO₃ in NH₃Aq by ferrous and manganous salts (P. 101, 264, 321, 497; v. also Weltzien, A. 142, 105). More recent experiments have shown that the products of such reductions in presence of alkali are mixtures containing Ag (v. Pillitz, Fr. 27, 496; Newbury, Am. 8, 196; Muthmann, B. 20, 983; Bailey a. Fowler, C. J. 51, 416).

Faraday (Q. J. S. 4, 268) supposed that a suboxide of Ag was formed by the action of air on an ammoniacal solution of Ag2O; but Bailey and Fowler (l.c.) have shown that the substance is a mixture of Ag₂O with a little explosive

silver.

The result of a long series of experiments by O. v. d. Pfordten (B. 18, 1407; 20, 1458; 21 2288, 3375) on reducing AgNO, Aq by H, PO, Aq, alkali bisulphites, and tartaric acid, is that the black pp. thus obtained is not a suboxide of Ag (for some time it was asserted to be AgiO); the accuracy of this result has been strengthened by the critical experimental work of Bailey (C. N. 55, 263; C. J. 51, 466), and especially of Friedheim (B. 20, 2554; 21, 307). F. regards the supposed Ag₄O as a mixture of finely-divided Ag with more or less Ag,O, or with some organic compounds. V. d. P. (B. 21, 2288, 3375) thinks his latest work points to the black substance being a compound of Ag, H, and O in the ratio 4Ag:2H:O; he gives it the formula Ag. H2O, or Ag. OH.H, and calls it silver hydrate. According to Güntz (C. R. 112, 861) Ag,O is produced by the action of steam on Ag₂F at 160

The question of the existence and isolation of a compound with less O than Ag.O cannot be

regarded as settled.

OXIDES OF SILVER WITH MORE OXYGEN THAN Ag₂O. By electrolysing conc. AgNO₂Δq, using Pt as positive and Ag as negative electrode, Ritter obtained a black deposit on the Pt; to this black substance R. gave the formula Ag.O. and described it as crystallising in octahedra, S.G. 5.474, giving up half its O when carefully heated, with NH3Aq evolving N, and with H2O2Aq production Ag, H.O, and O. A similar production of what seemed to be a peroxide of Ag was noticed by Fischer (J. pr. 33, 237) and by Wöhler (A. 146, 264). Böttger (B. 6, 1398) noticed that the peroxide produced by electrolysis formed explosive Ag and rapidly evolved N, with NH,Aq. Ag peroxide is formed by the action of ozone on Ag, according to Schönbein (J. pr. 41, 821); and of ozone on Ag2O according to Schiel (J. 1864. 118). Ag peroxide is an energetic oxidiser; it sets fire to H2S, and Au suiphide when rubbed therewith (v. Böttger, l.c.).

The analyses made by Fischer (J. pr. 33, 237), Mahla (A. 82, 289), and Gmelin (J. 6, 105) of the peroxide showed the presence of H₂O and AgNO₃; their preparations were probably impure. The analyses of Wallquist (J. pr. 31, 179) agreed well

with the formula AgO (or Ag.O.).

The supposed peroxide of Ag, prepared by secrelysing AgNO.Aq, is regarded by Berthelot (Bl. [2] 34, 138) as a compound of AgNO, with an oxide to which he gives the formula Ag.O.. By the interaction of H₂O₂Aq with Ag₂O, Berthelot (l.c.) obtained black flocks, which were separated from Ag by washing; to this substance B. gives the formula Ag,O, as the result of a not very complete analysis; he looks on it as probably identical with the product of the interaction of moist ozone and Ag or Ag₂O. This substance loses O when dried over H,SO,; with acids it gives salts of Ag₂O and evolves O.

Silver, oxychlorides of. The action of light on AgCl probably produces two oxychlorides of Ag; v. SILVER CHLORIDE, Action of light on,

p. 468.

Silver, oxyfluoride of. To the yellow crystals obtained by evaporating an aqueous solution of AgF, Pfaundler gives the composition AgF.AgOH

(W. A. B. 46 [2] 259).

Silver, phosphides of. Molten Ag absorbs P: according to Pelletier (A. Ch. 13, 101), some of the P remains in combination on cooling, but Warren (C. N. 56, 113) says that all except c. .002 p.c. separates as the Ag cools. According to Emmerling (B. 12, 152), a compound AgP is formed by heating Ag and P in a sealed tube to a dark-red heat; on heating the compound P is given off and Ag remains (v. also Landgrebe, S. 60, 128). By heating powdered Ag in vapour of P, Schrötter obtained a grey solid, S.G. 4-63, to which he gave the composition Ag₂P₃ (J. 1869.

Fresenius and Neubauer (Fr. 1, 340) obtained a pp. said to contain Ag phosphide and Ag, by leading PH₃, or CO₂ laden with vapour of P₃, into AgNO₃Aq; using PH₂ diluted with CO₂. Poleck and Thümmel (B. 16, 2435) obtained a

compound, probably Ag₃P.3AgNO₃.
Silver, photosalts of. Carey Lea (Am. S. [8] 33, 349, 480, 489; 34, 33; abstract in C. J. 54, 1) gives the name of photosalts to variouslycoloured compounds of Ag with the halogens which are very sensitive to light. These bodies are regarded by C. L. as identical with the substances that form the latent images on exposed photographic plates. The photosalts are obtained by the action of reducers, such as FeSO Aq or FeCl Aq, on the normal Ag haloids, by reducing Ag salts by such bodies as dextrose or tannin in presence of alkali and treating the products with HClAq, or by treating finely-divided Ag with the haloid salts of Cu or Fe and certain other halogenating reagents. The photosalts are regarded by C. L. as compounds of the normal haloids with sub-haloids; from the methods of preparation it seems fairly certain that the coloured bodies called photosalts contained various substances besides Ag and halogen.

Silver, platinocyanide of, v. vol. ii. p. 344. Silver, platinosulphocyanide of, v. vol. ii.

Silver, salts of. Compounds derived from acids by replacing II by Ag. These salts belong to the type AgX, where $X = NO_3$, $\frac{1}{2}SO_1$, $\frac{1}{2}CO_4$, $\frac{1}{3}PO_4$, &c. Subsalts of the type Ag_2X possibly exist, where X is a halogen. The principal silver salts of oxyacids are: arsenate and arscnite, borate, bromate, carbonates, chlorate,

chlorite, perchlorate and hypochlorite, caromass and dichromate, jodate and periodates, molubdates. nitrate, nitrite and hyponitrite, phosphates, selenate and selenite, sulphates, sulphite and thionates, tellurates and tellurite. Several salts derived from sulphur-containing acids also exist, the chief of which are: thio-antimonates and antimonites, thio-arsenates and arsenites, thio-carbonate, thio-molybdates, thio-phosphates

and phosphites, and thio-tellurite.

Silver, selenide of, Ag2Se. Occurs native, also in combination with selenides of Cu and Pb. Obtained by heating Ag with Se, SeO₂, or H₂Se; also by passing H₂Se into solution of a Ag salt; and by heating AgNO, Aq with Se (Senderens, C. R. 104, 175). A grey solid, melting at red heat to silver-white regulus. A little Se is lost by roasting in air; sol. conc. hot HNO, Aq, crystals of Ag, SeO, separating as liquid

Silver, selenocyanide of, v. vol. ii. p. 348. Silver, silicides of. Berzelius found that Ag after fusion with SiO, and C gave a residue of SiO, when dissolved in HNO₃Aq. Percy (Silver and Gold, 1, 131) failed to obtain any compound of Ag and Si. Warren (C. N. 60, 5) obtained compounds or alloys of Ag and Si by heating Ag with K.SiF, and Na.

Silver, silico-fluoride of, Ag.SiF. 2H.O. White, deliquescent crystals, melting below Ag with some SiO₂. Obtained by evaporating a solution of Ag₂O in H.SiF₄Aq (Marignac, Ann. M. [5] 15, 270).

Silver, sulphides of. The isolation of any sulphide other than AgaS is very doubtful.

SILVER SULPHIDE Ag.S. (Argentic sulphide.)
Mol. w. not known. Occurs native as argentits on red-hot AgCl (Durocher, C. R. 32, 823). H2S quite free from admixed O is said not to react with Ag. Also prepared by passing H2S into a solution of a salt of Ag; by boiling Ag, SO, Aq or AgNO, Aq with S (Filhol a. Senderens, C. R. 104, 175); and by the contact of H2SAq with moist Ag.O. Spring formed Ag.S by subjecting a mixture of Ag powder and amorphous S to a pressure of several thousand atmospheres, powdering, and compressing again, and repeating this treatment seven or eight times (Bl. [2] 39, this treatment seven of sight times $[Bt. [2] \ 30, 526]$, [641; 41, 488, 492; cf. Friedel, $Bt. [2] \ 40, 526]$. Thomsen (Th. 3, 381) gives [Ag; 8] = 5,340. Winssinger $(Bt. [2] \ 49, 452)$ obtained a dilute aqueous solution of colloidal Ag_2S by ppg. from a very dilute solution of a Ag salt, by H.S, and dialysing; the solution was reddish brown, and did not change after keeping for more than two months.

Ag2S obtained by ppn. is a black solid; when melted, out of air, it solidifies to a greyblack, lustrous, malleable mass, that can be cut with a knife; S.G. 685 (Karsten, S. 66, 394). S.G. of argentite 7.27 to 7.82 (Dauber, J. 13, 748). Heated in air slowly goes to Ag, giving off SO₂. With conc. boiling HClAq gives AgCl and H₂S; hot HNO₂Aq forms AgNO₂Aq and H.S; cone. H.SO, produces Ag.SO, and SO. Heated in Cl. AgCl and S.Cl. are formed. Reduced to Ag by action of metals and dilute acid; also reduced by heating with PbO, CuO,

16 3 3 3 4 4 4 4 4

Fe powder, or Hg (cf. Rammelsberg, C. J. 39.

Many compounds of Ag.S with metallic sulphides occur in minerals, e.g. with Cu,S, Sb₂S₂, As₂S₃, Bi₂S₃, &c. Schneider (J. pr. 41, 414) obtained a compound of Ag.S and Bi.S. by fusing the two sulphides together in a covered crucible. Poleck and Thümmel (Ar. Ph. [3] 22, 1) obtained Ag. S. Ag. NO. by passing H. S. into conc. AgNO3Aq so long as it was completely absorbed, washing the greenish pp. with HNO₃Aq, and drying; a black amorphous powdecomposed by water to Ag.S and AgNO,Aq.

SILVER SUBSULPHIDE. According to Güntz (C. R. 112, 861), Ag,S is obtained by the action of H.S on Ag.Cl.

Silver, sulphocyanide.of, v. vol. ii. p. 352.

Silver, telluride of, Ag.Te. Occurs native as hessite. Prepared by melting together Ag and Te, by passing vapour of Te diluted with much N over red-hot Ag (Margottet, C. R. 85, 1142), and by heating AgNO3Aq with Te in a sealed tube (Senderens, C. R. 104, 175). Grey, lustrous solid; obtained in needles (octahedral) by the second method given above. M. M. P. M.

SINALBIN C30H41N2S2O16. A glucoside occurring in the seed of white mustard (Will, Z. [2] 7, 89; A. 199, 150). Prepared by washing the seeds with CS, and extracting the residue with alcohol. Concentric groups of pale-yellow needles (from alcohol), v. sol. water, insol. CS2 and ether. Reduces Fehling's solution, with formation of Cu.S. Split up by the ferment myrosin into glucose, sinapine sulphate C₁₀H₂₂NO₃H₂SO₄, and C₂H₂OCNS, a pungent oil. Aqueous AgNO₄ produces a similar decomposition, forming a pp. whence H.S removes Ag, leaving in solution sulphate of sinapine and C₈II,NO [69°]. Coloured yellow by alkalis, and yields Na₂SO₄ and sodium sulphocyanide on boiling with NaOHAq. HgCl₂ gives a white pp.

SINAMINE v. ALLYL CYANAMIDE.

SINAPIC ACID C11H12O3. [192° cor.]. Formed, together with neurine, by boiling sinapine sulphocyanide with alkalis (Von Babo a. Hirschbrünn, A. 84, 19; Remsen a. Coale, Am. 6, 50). Small yellow prisms (from alcohol), sl. sol. cold water, insol. ether. The ammoniacal solution turns brown in air. Salt .- BaA" (dried at 110°). Pp.

Acetyl derivative C11H11AcO5. [281°]. Got by boiling the acid with Ac.O. White

crystals, sol. hot water.

SINAPINE C18H23NO3. Occurs as sulphocyanide in seeds of white mustard (O. Henry a. cyanide in seeds of white mustard (U. Henry a. Garot, J. Ph. 17, 1; 20, 63; Pelouze, A. Ch. [2] 44, 214; J. Ph. 17, 271; Boutron a. Robiquet, J. Ph. 17, 279; O. Henry a. Plisson, A. Ch. [2] 46, 198; Winckler, Rep. Pharm. 41, 169; 67, 257; Simon, P. 43, 651; 44, 593; Boutron a. Fremy, J. Ph. 26, 50; Von Babo a. Tringht in A 24, 10. Ramsen a Coale Am. Hirschbrünn, A. 84, 10; Remsen a. Coale, Am. 6, 50). Formed also by the action of myrosin on sinalbine (Will a. Laubenheimer, A. 199, 162). The free base is known only in solution, and is decomposed on evaporation, leaving a resin. Boiling baryta-water splits it up into neurine C₂H₁₈NO₂ and sinapic soid.

Salts.—B'H₂SO₄2aq: rectangular plates, v. sol, water and hot alcohol, nearly insol, ether .--B'HHgCl₃: thin prisms.—B'HCNS. [176°].

SINAPOLINE v. DI-ALLYL URBA.

SINCALINE v. NEURINE.

SINISTRIN v. Inulin. SIPERINE. An amorphous, resinous, alkaloid occurring, together with bebirine, in the greenheart tree (Nectandra Rodiai or Bebeeru Sipceri). It is v. sl. sol. water, m. sol. alcohol, insol. ether (Maclagan, A. 48, 106).

SKATOLE v. METHYL-INDOLE.

SKELETINS v. Proteins, Appendix C.

SKIMMIN C₁₃H₁₀O₂. [210°]. A glucoside extracted by alcohol from Skimmia japonica (Eijkman, R. T. C. 3, 204). White needles, sl. sol. cold water. Its alkaline solutions show blue fluorescence. It is not poisonous, and does not reduce Fehling's solution.

Skimmetin C,H,O,. [223°]. Formed, to-gether with glucose, by boiling skimmin with dilute mineral acids. Colourless crystals, sol. alcohol and ether. Its solutions exhibit blue fluorescence. Does not reduce Fehling's solution. FeCl, gives a blue colour. Gold chloride gives a rose colour, turning blue and violet.

SMILACIN C₁₈H₃₀O₆(?). Occurs in sarsa-parilla root (Smilax Sarsaparilla) (Reinsch, Rep. Pharm. 82, 145; Thubeuf, A. 5, 204; 14, 76; Batka, A. 11, 305; Poggiale, A. 13, 34; Henry, A. 14, 77; Petersen, A. 15, 74; 17, 166; Wright a. Rennie, C. J. 39, 237). Nodular groups of leaflets, m. sol. hot water and alcohol, sol. alkalis.

Reference.-Parillin.

SNAKE POISON v. PROTEÏDS.

SOAP v. DICTIONARY OF APPLIED CHEMISTRY. **SOBREROL** $C_{10}H_{18}O_2$. [150°]. [a]₀ = ± 150°. A product of atmospheric oxidation of turpentime in sunlight (Armstrong a. Pope, C. J. 59, 316). Long tables (from alcohol) or monoclinic prisms (from water); a:b:c = 2.411:1: 853; $\beta = 83^{\circ}38'$. Tastes bitter. Converted by boiling dilute H.SO, into an oily isomeride of cam-phor. By crystallising a solution of equal quantities of dextro- and lævorotatory sobrerol there is obtained an inactive sobrerol [131°] crystallising from alcohol in trimetric tables; a:b:c = 2.424:1; .827.

SOCALOÏN v. ALOÏN.

SODA; v. Sodium hydroxide, p. 479. SODIUM Na. At. w. 22 995. Mol. w. very probably same as at. w. (v. infra). Melts at 95.6° (Bunsen, A. 125, 367), 97.6° (Hagen, W. 19, 436); solidifies at 97.6° (Regnault, J. 1856. 43). Boils between 860° and 950°, according to Carnelley and Williams (C. J. 35, 565); at 742° (Perman, C. J. 55, 326). S.G. 985 40 (Schröder, P. 106, 226); 9743 at 10° (Baumhauer, B. 6, 655); c. 74 at b.p. (Ramsay, C. J. 39, 49). V.D. 12.7 at 1200°-1500° (Scott, Pr. E. 14, 410; v. infra). S.H. 2734 from -28° to 6° (Regnault, A. Ch. [6] 146, 257); '21 when liquid (Joannis, A. Ch. [6] 12, 358). C.E. (0° to 50°) '00007105 (Hagen, W. 19, 436). E.C. (Hg at 0° = 1) 18·3 solid at 0°, 8·3 liquid at 120° (Matthiessen, P. M. [4] 12, 199; 13, 81). T.C. (Ag=100)=36.5 (Calvert a. Johnson, P. M. [4] 16, 881). H.C. [Na2,O] = 99,760 (Th. [8] 282). Refraction-equivalent $\frac{\mu - 1}{d}$ × at. w. = 4.4 (Gladstone, Pr. 18, 49);

4.03 (Kanonnikoff, J. R. 1884 [i.] 119). Emission spectrum characterised by a double line D, the components of which have the wave-lengths 5895 and 5889 (for detailed measurements of lines v. B., A. 1884. 443). For absorption spectrum v. Roscoe a. Schuster (Pr. 22, 362). S.V.S. solid 23.3; at b.p. 31 (Ramsay, C. J. 39, 49).

Occurrence. - Compounds of Na occur widely distributed in large quantities. NaCl is found abundantly as rock-salt, also in sea-water and many mineral springs. Large quantities of NaNO, or Chili saltpetre occur in S. America. Carbonate, sulphate, and borate of Na are found, in comparatively small quantities, in rocks, and in lake and spring waters. Cryolite is a double fluoride of Na and Al. Many silicates contain Na silicate-e.g. natrolite, albite, labradorite, &c. The ashes of many plants contain Na salts, especially NaCl, NaI, and Na,SO,; some plant ashes are free from Na salts, even when the plants grow near the sea; the ashes of algor and some other sea plants are richer in salts of K than in those of Na. NaCl, Na₂CO₃, Na₂HPO₄, and some other compounds of Na, are found in animal organishs.

Historical. - Caustic soda was decomposed by Davy in 1807 (T. 1808. 1) by electrolysis; Gay-Lussac a. Thénard heated NaOH with Fe filings and obtained Na (A. Ch. 65, 325 [1808]). Brunner (S. 71, 201) reduced Na₂CO₃ by heating with charcoal; this process was made applicable on the large scale by Deville (A. Ch. 3)

43, 5 [1855]).

The word neter is used by the older Hebrew writers to denote a substance employed for washing clothes; the same, or a similar, substance seems to have been known as vitpov or nitrum, and by the fifteenth century this name was given to saltpetre; when the existence of two similar but distinct substances having detergent properties was recognised, the name nitrum was given to one, and the other was called natrum or natron. The metal obtained from natron was called natrium; this name is retained in German, but in English and French the metal is named from soda, a word applied in the Middle Ages to designate alkaline substances, and used as synonymous with nitrum and natron. The symbol Na is universally employed for the metal.

Formation .- 1. By electrolysing NaOH (cf. Potassium, Formation, No. 1, p. 298).—2. By reducing Na₂CO₃ by heating it with charcoal, or with charcoal and very finely-divided iron (Castner, C. N. 54, 218).—3. By electrolysing fused NaCl, or conc. NaClAq, using Hg as the

negative electrode.

Preparation .- 1. An intimate mixture of 80 parts calcined Na CO3, 13 parts coal, and 5 parts chalk is heated in an iron bottle with a short exit tube, in a furnace, until vapours of Na appear at the mouth of the tube, when a small flat receiver, made of sheet iron, is adapted to the tube; when the receiver is full of Na it is removed, and the metal is taken out under mineral oil (cf. Potassium, Preparation, p. 298). As Na does not combine with CO, the difficulty which attends the preparation of K because of the formation of KCO, does not occur with Na.-2. A mixture of NaOH, C, and Fe is heated in egg-shaped iron retorts, connected with cast-iron condensers about 3 ft. long and 5 in. diameter, and having small openings near the nozzles through which the molten Na runs into pots placed beneath. The mixture of C and Fe is made by heating a mixture of very finely divided iron and pitch; this is heated with NaOH in approximately the proportion 6NaOH:2C:4Fe. (For details v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 422.)

The metal is purified by pressing through linen under rock oil kept at c. 100°; it must be kept under oil free from O. Rosenfeld (B. 24, 1658) recommends to soak the metal in a mixture of 1 part amyl alcohol and 3 parts petroleum, and to rub it with a rag soaked in the same mixture, till the surface is bright; then to let it remain under petroleum with 5 p.c. amyl alcohol; to wash it with pure petroleum, and to keep it under petroleum containing from 1 to 1 p.c. amyl alcohol. The film of sodium-amyl oxide which forms is easily rubbed off with filter

Properties. - A silver-white, lustrous metal: usually described as whiter than K, but according to Long (C. J. 13, 122) a clean surface has a pale rose colour. By melting Na in a glass tube, narrowed at one place, and filled with coal-gas or H, and allowing the semi-solidified metal to flow slowly through the narrowed part of the tube, Na is obtained in lustrous, white, quadratic octahedra, with a rosy sheen (Long, l.c.; cf. Böttger, B. 7, 1536). According to Linnemann (J. pr. 75, 128), the surface of a freshly-cut piece of Na shows green phosphorescence that soon disappears, but returns again at 60°-70° (cf. Baumhauer, J. pr. 102, 123, 361). A sublimate, in a very thin film on glass, shows a greenish blue colour in transmitted light (Dudley, C. N. 66, 163; Newth, N. 47, 55). The vapour obtained by boiling Na in an atmosphere of H is colourless in thin layers, and violet to purple when seen in thick layers (Roscoe a. Schuster, Pr. 22, 362; Carnelley a. Williams, C. J. 35, 565). At the ordinary temperature Na is as soft as wax; it is ductile at 0°, and fairly hard at -20° ; at c. 50° it is pasty; it melts at c. 96° , and boils at c. 750° (v. beginning of this article). Na dissolves in liquid NH3, forming a blue liquid (v. Sodium-ammonium, p. 475). A freshly-cut surface of Na exposed to air becomes rapidly covered with a film of oxide; Na is said to be unchanged at the ordinary temperature in perfectly dry air. It decomposes cold water rapidly, but the H evolved does not generally take fire. Na must be kept under a liquid free from O, such as mineral oil or naphtha (v. Preparation, supra).

The atomic weight of Na has been determined (1) by converting NaCl into AgCl (Berzelius, P. 8, 189 [1826]; Pelouze, C. R. 20, 1047 [1845]; Dumas, A. Ch. [3] 55, 182 [1859]; Stas, Stas, Rech. 78); (2) by reducing NaClO, to NaCl (Penny, T. 129 [1] 25 [1839]); (3) by converting NaCl into NaNO₃ (Stas, Nouv. R. 248 [1865]);
(4) by determining S.H. of Na.

The molecular weight of Na is not known with

certainty. Dewar a. Dittmar (C. N. 27, 121) and D. a. Scott (Pr. 29, 206 [1879]) obtained numbers that indicated a mol. w. of 23; but the values varied considerably. D. a. S. used a vessel of wrought iron. Scott (Pr. E. 14, 410 [1888]) ob-

tained fairly concordant results, giving values for V.D. varying from 11.8 to 15, using a Pt vessel heated above the m.p. of cast iron; but V. Meyer's experiments (B. 13, 391 [1880]) seemed to indicate that Na vapour attacks vessels of Ag or Pt. Mitscherlich (A. 12, 173 [1834]) found that vessels of hard glass were also attacked; and Rieth (B. 4, 807 [1871]) got no constant results by using a vessel of Cu. The values obtained by Scott were so constant that there is a large probability in favour of the monatomicity of the molecule of gaseous Na. Ramsay (C. J. 55, 521) dissolved Na in Hg and measured the decrease of vapour-pressure of the Hg thereby produced; assuming the mol. w. of liquid Hg to be 200, and assuming that equal vols, of dilute solutions in Hg contain equal numbers of molecules, the results gave values for mol. w. of Na varying from 15 to 21.5.

The V.D. of no compound of Na has been determined; from the analogy of K, Rb, Cs, and Ag, the atom of Na is probably monovalent in

gaseous molecules.

Sodium is a strongly positive element; it comes after Rb. Cs. and K in order of decreasing electropositiveness (Bunsen). In all its compounds Na reacts as a metal; it does not enter into the composition of any negative radicles. Na forms few basic salts and no oxyhaloid compounds; its haloid compounds are very stable towards heat. Na is closely related to Li, K, Cs, and Rb (v. Alkalis, METALS OF THE, vol. i. p. 114), and less closely to Cu, Ag, and Au (v. Copper group of elements, vol. ii. p. 250).

Reactions and Combinations .- 1. Heated in air or oxygen, Na₂O and Na₂O₂ are formed (v. Oxides, p. 482). According to von Bonsdorff (P. 41, 296), Na is unchanged in quite dry air at the ordinary temperature.—2. Na absorbs hydrogen at c. 300°, probably forming a compound (v. Hydride, p. 479). -3. Combines with chlorine, bromine, and iodine when heated with these elements (v. Chloride, bromide, and iodide). -4. Forms sulphides, by reacting with sulphur at the ordinary temperature; combines, when heated, with selenion and tellurium, also with arsenic and phosphorus (v. Sulphide, p. 483, Selenide, p. 482, Telluride, p. 483, Arsenide, p. 476, and l'hosphide, p. 482).—5. Alloys with several metals (v. Alloys, infra).—6. Na decomposes water at the ordinary temperature, forming NaOHAq and H; much heat is produced, but the H does not generally take fire unless the reaction is slackened, and friction is increased, by thickening the water by gum &c., or placing the Na on moist filter paper (v. Ducatel, Am. S. 25, 90; Serullas, A. Ch. [3] 40, 329). If Na is allowed to react with water in a cylinder standing over water, the H collecting in the cylinder, a violent explosion sometimes occurs, probably due to formation of a peroxide that is then decomposed with evolution of O, which mixes with the H (Böttger, J. pr. 85, 397; Griffin, J. 1856. 320) .- 7. Na reduces many oxides at high temperatures, e.g. CO, N₂O, B₂O₃, P₂O₅, As₂O₅, HgO, CuO, Ag₂O, PbO, ZnO, Fe₂O₅, &c.—8. Many carbonates, sulphates, nitrates, phosphates, and silicates are reduced when strongly heated with Na .- 9. Many metallic chlorides are reduced by heating with Na, s.g. MgCl, AlCl, &c .- 10. By heating with solid caustic potash to c. 170°, an

alloy of Na and K is formed (v. Williams, C. N. 3, 21; Wanklyn, C. N. 3, 66).-11. Heated in anmonia gas, NaNH, is formed (v. Amide, infra), and when this is more strongly heated Na₃N is formed (v. Nitride, p. 482).—12. Na reacts with aqueous solutions of acids to form salts NaX, where X is a monovalent acidic radicle.

Sodium, alloys of. Na forms alloys with many metals; these alloys are generally formed by directly melting the metals together, or by reducing the chlorides by Na. By the action of sodammonium (v. infra) on Sb. Bi. Pb. Joannis (C. R. 114, 585) says that alloys of Na with these metals are obtained agreeing in composition with the formulæ Na, Sb, Na, Bi, and NaPb. Schumann (W. 43, 101) obtained a definite alloy of Na and Hg corresponding with the formula NaHg, (v. also Sodammonium, infra).

Sodium, aluminates of, v. vol. i. p. 141.
Sodium, amide of, NaNH... (Sodamide.)
Mol. w. not determined. First prepared by Gay-Lussac and Thénard (Recherches physico-chimique, 1, 354) by heating Na in NH₃; the Na absorbed 142 to 163 vols. NH3 and 100 vols. H were produced. Prepared by Beilstein and Geuther (A. 108, 88) by driving out the air from several flasks, connected by tubes, by a stream of dry H, then placing a few grams Na in each thask, replacing the H by dry NH₃, free from CO₂ (Drechsel, J. pr. [2] 16, 203), and heating the flasks on sand-trays; the Na melts and swims on the blue-green liquid that forms. When the Na has all disappeared the liquid is allowed to cool; the solid that forms is at first brown, but when quite cold it forms a crystalline, olive-green mass. Also obtained by the gradual decomposition at the ordinary temperature (hastened by light) of sodammonium; as the liquid decomposes, crystals of NaNII₂, 1 mm., long, are formed; these crystals are said to be white (Joannis, C. R. 112, 392).

Heating in CO produces NaCN and H.O. along with NaOII and NH3. When heated in CO2 much NH3 is given off, and the final pro-[2] 21, 91). When strongly heated NaNH, given off NH, and leaves NaN, (v. Sodium nitrade, p. 482).

Sodium-ammonium or Sodammonium. Weyl (P. 121, 611; 123, 350) obtained a blue liquid, by the action of liquid NH, on Na, which he regarded as a compound or alloy of Na and NH. As Na remained when the NH, was allowed to evaporate, Seeley (C. N. 23, 169) looked on the blue liquid as a solution of Na in liquid NH.
Joannis (C. R. 109, 900, 965; 110, 238) found that the vapour-pressure of a solution of Na in liquid NH, decreased to a limit whereat it became constant if temperature remained unchanged; that on then removing more NH, a copper-red solid separated, and that NH, was then given off at constant pressure till only Na remained. When the last part of the change commenced, the copper-red substance contained

Na and NH, in the ratio Na:NH,; the evolution of NH, at constant pressure was regarded by J. due to the dissociation of a compound NaNH. The heat of formation of NH, Na from gaseous NH, and solid Na was determined by J. to be 5,200, and from liquid NH, and solid Na to be 800, cals. J. determined the lowering in the freezing-point of liquid NH, by solution in it of NaNHa, and so calculated the mol. formula of this body to be Na, N₂H₆ (C. R. 115, 820). The solution of Na₂N₂H₆ in liquid NH₅ is decomposed by Sb, Pb, and Hg, but not by Al, Cu, Ag, or Zn; the final product of the action of Pb is Pb,Na.2NH,; by dropping the liquid on to Hg, and washing the product with liquid NH, the crystalline amalgam NaHg, was obtained (J., C. R. 113, 795). According to J. (C. R. 112, 392), Na₂N₂H₆ decomposes slowly at the ordinary temperature to NaNH, and H. With excess of NaCl the blue liquid becomes colourless and NaNH, separates; the compound NH2NaCl is first formed, and is then decomposed by the liquid NH, to NaNH, and NaCl. By passing dry O into Na, N, H, in liquid NH, at -50°, J. (C. R. 116, 1370) obtained NH, Na, OH; by the prolonged action of O he obtained Na₂O₂.
Sodium, arsenates of, v. vol. i. p. 309.

Sodium, arsenide of. Gay-Lussac and Thenard found that Na combined directly with As. According to Landolt (A. 89, 210) Na, As is formed, as a silver-white solid, by heating the elements in the ratio 3Na:As. A compound of Na and As is also formed when Na is heated in AsH₃. Decomposed by water, giving off AsH₃. Sodium, arsenites of, v. vol. i. p. 307.

Sodium, aurobromate of, NaAuBr. Orangered prisms, by dissolving NaBr in AuBr, Aq (cf. vol. ii. p. 649).

Sodium, aurochlorate of, NaAuCl. By dissolving NaCl in AuCl. Aq (cf. vol. ii. p. 650).

Sodium, borates of, v. vol. i. p. 529. Sodium, boride of. The product of the reduction of B2O3 by Na may contain a compound of B and Na.

Sodium borofluoride v. vol. i. p. 526.

Sodium, bromide of, NaBr. Mol. w. not certainly known, but probably 102 745 (= NaBr). Welts at 708° (Carnelley, C. J. 33, 279); at 727° (c. Meyer a. Riddle, B. 26, 2443). S.G. 3079 at 17.5° (Kremers, P. 99, 443); 3.198 at 17.3° (Favre a. Valson, C. R. 77, 579); 2.448 when molten (Quincke, P. 138, 141). Krervers (P. 99,

40) gives	BOIDDIIITIES	88	IOHOWS:—	
Temp.	s.	- 1	Temp.	8.
0°	77.5	- 1	60°	111-1
20	88.4	- 1	80	112.5
40	104.2	- 1	100	114.9

Coppet (A. Ch. [4] 25, 506; [5] 30, 411) gives the following:-

Temp.	· 8.	Temp.	8.
44·1°	115-6	86°	118.8
51.5	116-2	90.5	119.7
55·1	116.8	100.3	120.6
60.8	117	110-6	122.7
64.5	117.8	114-8	124
74.5	118-4		

C. represents S. of NaBr as 110.84 + 1075t when twaries from 44° to 114°. S. in alcohol 90 p.c. = 6. B.P. of saturated NaBrAq = 121°. S.G.

of NaBraq given by Kremers a. Gerlach (Br. 6, 279) at 15° as follows:—

3.G. NaBrAq	P.O. NaBr	S.G. NaBrAq	P.C. NaBr
1.04	5	1.281	80
1.08	10	1.344	- 35
1.125	15	1.410	40
1.174	20	1.483	45
1.226	25	1.565	50

H.F. [Na,Br] = 85,770; [Na,Br,Ad] = 85,580 (Th. 3, 232).

Formation.-1. By passing Br vapour over Na. According to Merz and Weith (B. 6, 1518), Na remains unchanged for months in liquid Br at the ordinary temperature, and even at 100° or 200° the formation of NaBr proceeds very slowly.—2. By treating BrAq with iron filings, boiling the solution of FeBr₂Aq with NaOHAq, filtering, and evaporating (Henry, J. Ph. 15, 54).—3. By neutralising HBrAq by NaOHAq or Na CO Aq, and evaporating. -4. By decomposing CaBr.Aq by Na.SO, filtering after some time, adding Na CO, as long as turbidity is produced, filtering, and evaporating (Klein, A. 128, 237).— 5. By decomposing pure NH₄Br by NaOHAq or Na, CO, Aq, and evaporating (Castelhaz, C. R. 70, 1050).

Preparation.—Br is added, little by little, to moderately conc. pure NaOHAq (v. Sodium hydroxide, p. 479) till the liquid is slightly yellow; the liquid is evaporated to dryness; the residue of NaBrO, and NaBr is strongly heated, in a porcelain dish, till traces of Br are given off, the residue is dissolved in water, evaporated, and allowed to crystallise at a temperature not under 30° (NaBr. 2aq separates below 30°).

Properties.—Lustrous, white cubes; strong alkaline taste; reaction in water is neutral. Dissolves easily in water, with slight fall of temperature [NaBr,Aq] = -190 (Th. 3, 232); NaBr separates from this solution at c. 30° but at the ordinary temperature crystals of NaBr. 2ag are formed.

Reactions.-1. Chlorine reacts with NaBrAq to give NaClAq and Br.-2. Heated with potassium chromate and sulphuric acid, Br is given off: NaCl under similar conditions gives CrO2Cl2.-3. Conc. sulphuric acid forms HBr, Br, and SO₂; by using dilute H₂SO₄Aq (c. 30 p.c.) a mere trace of Br is obtained (v. Addyman, C. J. 61, 94).-4. Potassium permanganate does not react with NaBrAq even when boiled, but addition of a little H₂SO₄Aq causes evolution of Br (Hempel, A. 107, 160).

With water to form

NaBr.2H2O. This hydrate separates from solutions of NaBr saturated when hot and cooled to under 30°; it crystallises in monoclinic prisms, which melt at 50°, leaving NaBr.-2. With many bromides of less positive metals, e.g. with PbBr, to form PbBr, 2NaBr, and CdBr, to form CdBr, 5NaBr. 5aq (v. the various metallic bromides).—3. With arsenious oxide to form

NaBr.As,O. (Rüdorff, B. 21, 3051).
Sodium, chloride of, NaCl. (Common salt.) Mol. weight not known with certainty, but pro-bably 58-365 (= NaCl). Melts at 772° (Carnelley, C. J. 33, 280); at 851° (Meyer a. Riddle, B. 26, 2443). S.G. 2-16 at 0° (Quincke, P. 138, 141); 2-157 at 4° (Schröder, P. 106, 226); (7) 1-612 at m.p. (Braun, B. 7, 958); 2-04 after fusion (Quinoke, P. 185, 642); for other values v. Clarke's Table of Specific Gravities [2nd ed.] 20. S.H. 15° to 98° 21401 (Regnault, A. Ch. [3] 1, 129; v. also Kopp, T. 155 [i.] 71. Vol. at 40° = vol. at 0° (1 + 00012117 × 40) (Fizeau, C. R. 64, 314). H.F. [Na, Cl] = 97,690 (Th. 3, 232). Poggiale (A. Ch. [3] 8, 469) gives following data for solubility in water:—

Temp.	- 8.	Temp.	8.
-15°	32.73	40°	36.64
-10	33.49	50	86.98
- 5	84.22	60	37.25
0	35.52	70	37.88
+ 5	85.63	80	38.22
9	35.74	90	38.87
14	35.87	100	39.61
25	36.13	109.7	40.35

Coppet (A. Ch. [5] 30, 411) gives S. above 20° to $109^{\circ} = 34 \cdot 359 + 0527t$. Gerlach (Fr. 8, 281) gives the following data:—

	S.G. NaC	IAq at 15°	
1 p.c.	1.00725	10 p.c.	1.14315
2 ,,	1.01450	11 ,	1.15107

4 ,,	1.02899	13 ,,	1.16755
5 ,,	1.03624	14 ,,	1.17580
6 ,,	1.04366	15 "	1.18404
7 ,,	1.05108	16 ,,	1.19228
8 ,,	1.05851	17 ,,	1.20098
9 ,,	1.06593	18 ,,	1.20433

1000 c.c. of NaClAq saturated at 15° contain 318479 g. NaCl and 888°669 g. water (Michel a. Kraft, J. 1854. 29°). NaClAq containing 29°4 to 29°5 p.c. NaCl boils at 109°25° (at 760 mm. pressure) and freezes at -21°3° (Karsten, Salimenkunde [Berlin, 1847] 2,38). The following freezing-points are given by Karsten (l.c.) for NaClAq (cf. Rüdorff, P. 114, 63°; and de Coppet, A. Ch. [4] 25,509):—

P.C. NaCl	F.P.	P.O. NaCl	F.P.
2	-1·32°	16	-11.69
4	-3.024	20	-14.44
6	-4.52	22	-15.78
8	 5 ·99	24	-17:11
10	-7·44	26	-18.42
12	- 8.88	1	

For freezing-points of dilute NaClAq, containing from c. 006 to c. 2.6 p.c. NaCl, v. Jones (Z. P. C. 11, 210).

Solution of NaCl in water is accompanied by lowering of temperature and contraction; 36 parts NaCl in dissolving in 100 parts water at 12:6° lower the temperature to 10:1° (Rüdorff, B. 2, 68); Thomsen gives [NaCl,Aq] = -1180 (Th. 3, 252). By mixing 36 parts NaCl with 100 parts snow, temperature falls to -21:3° (Rüdorff, P. 114, 79; 122, 337).

NaCl is insol. absolute alcohol; Girardin A. Ch. [4] 5, 146) gives the following data for S. in aqueous alcohol S.G. 9282; 10-9 at 49, 11-1 at 10°, 11-43 at 13°, 11-9 at 23°, 12-3 at 32°, 13-1 at 44°, 13-8 at 51°, 14-1 at 40°. Schiff (A. 118, 365) gives S. in alcohol at 15° as follows; 28-33 in 10 p.c. alcohol, 13-25 in 40 p.c., 5-93 in 60 p.c., 1-22 in 80 p.c. NaCl crystallises in the regular system, generally in cubes, sometimes in ootahedra.

Occurrence.—As rock salt, or halite, in very

large quantities very widely distributed; in seawater, many salt lakes, brine springs, and most mineral springs.

Fornation.—1. By burning Na in moist Cl. According to Wanklyn (C. N. 20, 271), dry Cl does not combine with Na even at the M.P. of the metal; Donny a. Marceka (C. R. 20, 817) state that Na is unacted on by liquid Cl at —80°.—2. By neutralising NaOHAq or Na₂CO₃Aq by HClAq, and evaporating.—8. By the reaction of excess of cone. HClAq with several salts of Na, e.g. Na₂SO₄.—4. By strongly heating Na₂SO₄ with excess of NH₁Cl; also by decomposing Na₂SO₄Aq by several chlorides, e.g. MgCl₂ or CaCl₂.—5. As a by-product in making KNO₃ by the reaction of KCl with NaNO₅. By the reduction of many chlorides by Na.

Preparation. - Pure NaHCO, is prepared by washing a large quantity of the ordinary ' pure salt, in fine powder, with cold water till the washings cease to be clouded on addition of a salt of Ag or Ba; after boiling with slight excess of HNO Ag, the residue is dried and heated to dull redness in a Pt dish; a boiling saturated solution of the Na₂CO₃ thus obtained is prepared, filtered, and shaken while crystallising to insure the formation of small crystals; the crystals are dried by suction by a water-pump, they are then twice moistened with cold water to remove all mother-liquor, and crystallised three times from water. The pure Na,CO, is dissolved, and NaCl is formed by passing in a stream of pure HCl gas (obtained by heating pure conc. HClAq); a little pure NH₄Cl is added to the solution (for preparation of pure NH,Cl v. vol. i. p. 197, under Ammonia, Preparation, No. 3), which is then evaporated to dryness in a Pt retort; the residue is very strongly heated, and then dissolved in water; after standing for 24 hours the solution is poured off (from any Al2O3.xH2O and SiO₂ that settle), a little pure NH₄Cl is added, the solution is evaporated to dryness in a Pt retort, the residue is strongly heated for some time, and after partial cooling the still liquid NaCl is poured off (from Pt, SiO2, and Al₂O₃) into a Pt dish; when cold, the NaCl is dissolved in water, the solution is poured off after 2 days and evaporated to dryness in a Pt retort, and the residue is fused in a Pt vessel (Stas, Chem. Proport. 275).

For preparation of Nacl from rock salt, brine, and sea-water, v. Distributor of Applied Chemistry, vol. iii. p. 429.

Properties.—A pure, white, lustrous solid; crystallises in the regular system, generally in cubes. Decrepitates when heated. NaCl is diathermanous. Solution in water is neutral to indicators, and has a bitter taste. Pure NaCl is very slightly hygroscopic, taking up c. ‡ p.e. water from moist air (Stas, Karsten). Melts at c. 772°; vapourises markedly at white heat in a stream of N (v. Stas, l.c.). NaCl is almost wholly ppd. from an aqueous solution by leading in HCl (Margueritte, C. R. 4°, 50); also ppd. from a conc. solution by cold conc. NaOHAq (Berthelot C. R. 76, 111); also by warming a conc. solution with excess of NaBr or NaI and cooling (von Hauer, J. pr. 98, 187). Saturated NaClAq deposits the hydrate NaCl. 2aq at — 7° to o. — 22°, and at c. — 23° NaCl. 10aq separates (v. Hydrates under Combinations, p. 478).

Reactions .- - 1. According to de Sanderval (C. R. 116, 641), when NaCl is vapourised around a porous tube Cl collects in the inside of the tube.—2. Electrolysis of NaClAq produces Cl and NaOHAq, but NaClOAq and NaClO, are soon formed by secondary reactions; if a diameter of the control of the collect of the tube. phragm of asbestos is used, the cathode being on one side and the anode on the other, and CO₂ is passed into the NaClAq, Cl is given off and Na₂CO₃ is formed (v. Hempel, B. 22, 2475).— 8. Fusion with potassium produces KCl and Na. 4. Fusion with sulphur is said to form Na₂S and S₂Cl₂, but this is denied by Karsten; NaCl is not decomposed by hydrogen, or oxygen, at a red heat.—5. Superheated steam has no reaction, according to Kunheim (J. 1861. 149); there is a slight reaction, according to Lunge (Soda-indusslight reaction, according to Lunge (Soda-industrie, 2, 288).—6. Sulphuric anhydride vapour is absorbed, without heating, giving S₂O₂NaCl (Na salt of SO₂(Cl).O.SO₂.OH); according to Schultz-Sellack (B. 4, 112) more SO₂ is then absorbed, and a compound approximately NaCl.4SO₂ is formed; on heating Na₂SO₃ SO₂ and Cl are produced. By heating with liquid sulphuric anhydride S₂O₃Cl₂ is formed (Rosenstiah), C. R. 53, 658).—7. Decomposed by heating the composed by heating the composed of stiehl, C. R. 53, 658).—7. Decomposed by heating to c. 500° in a mixture of air, sulphur dioxide, and water vapour, giving Na₂SO₄ and HCl (Hargreaves and Robinson's process for making Na₂SO₄; v. Dictionary of Applied Chemistry, vol. iii. p. 444). - 8. NaCl is decomposed, with formation of oxychlorides or chlorides, by heating with phosphoric, chromic, or molybdic anhydride, or with antimonic oxide; decomposition occurs with silica, boric oxide, alumina, and tungstic oxide only in presence of air or water vapour, forming silicate, borate, aluminate, or tungstate of Na, and HCl; in presence of water vapour Cl is evolved in some of these reactions (v. Schulze, J. pr. [2] 21, 407; Delalande a. Prudhomme, Bl. 20, 74; Gorgeu, A. Ch. [5] 10, 145). Lead oxide decomposes NaClAq, forming PbCl, and NaOHAq (Scheele); but molten NaCl is said not to interact with PbO. Moist NaCl mixed with caustic lime and exposed to air becomes covered with an efflorescence of Na CO, crystals. Magnesia interacts with NaclAq, in presence of CO₂, to form NaHCO₃ and MgCl₂ (Weldon; Wagner, J. 1873, 256).—9. Sulphuretted hydrogen partially decomposes hot NaCl to Na,S, more completely in presence of steam (Kingzett, C. J. [2] 11, 456).—10. Many metallic sulphides, e.g. Cu.S, produce Na.SO, and metallic chlorides (someproduce Na, 50, and metalite emotides going times Cl is set free) when roasted in air with NaCl,—11. Several metallic sulphates when fused with NaCl produce Na, 50, and metallic chlorides—c.g. PbSO, ZnSO, CuSO,; some of these sulphates react also with NaClAq. Some sulphates form Na, SO, and give off Cl when the contraction of the NaclAq. sulphates form Na, SO, and give off Ci when heated with NaCl, e.g. FeSO, (v. Barreswil, J. Ph. [8] 12, 456),—12. Fusion with potassium chlorate only decomposes a trace of NaCl (Schulze, J. pr. [2] 21, 407).—13. Ammonium oxalate heated with NaCl forms Na, CO, and disozalate heated with NaCi forms Na,CO, and distinct quantities of NaCi (Fresenius); addition of (NH₁)₂C₂O, to hot saturated NaClAq ppts. Na,CO,-—14. Potassium carbonate reacts with NaClAq to form Na,CO₂Aq and KClAq; if CO₂ is passed in NaHCO₂ ppts.—15. Ammonium bicarbonate and NaClAq produce NaHCO₂ and

NH.ClAq. Passage of CO, into NaClAq saturated with NH, ppts. NaHCO, (v. Ammonia-soda process, in Diotionary of Applied Chemistry, vol. iii. p. 494).—16. Sulphuric acid decomposes NaCl, forming HCl, and NaHSO, or Na,SO, according to the temperature. The Lebland process for making sodium carbonate takes advantage of this reaction (v. Dotionary of Applied Chemistry, vol. iii. p. 459).—17. Evaporation with excess of nitric acid produces NaNO₃ and HCl.—18. NaCl is readily decomposed by hydrofluoric acid, also by hydrofluoristicic acid.—19. Carbonic acid is said to set free some HCl from NaClAq (v. H. Müller, B. 3, 40; Funk, Chem. Zeitung, 1879. 660).—20. Repeated evaporation with excess of cashic acid completely decomposes NaCl to Na,ClQ.

Combinations.—1. With water to form hydrates. The dihydrate NaCl. 2aq separates from saturated NaClAq cooled to —7° to —22°, in large clear monoclinic crystals (v. Hankel, P. 53, 623; Mitscherlich, J. pr. 83, 485). The crystals cfiloresce at —10°, and deliquesce at 0°. Ehrenberg (P. 36, 210) and Frankenheim (P. 37, 638) obtained this hydrate by evaporating dilute NaClAq at a moderate temperature. The crystals that separate from hot NaClAq containing HCl are hydrated, according to Bevan (C. N. 35, 17), and contain 5·48 p.c. water, but after a time they change to the ordinary crystals of NaCl. According to Naumann (Thermochemie, 106), crystals of the decahydrate, NaCl. 10aq, separate from NaClAq at —23°.—2. NaCl absorbs considerable quantities of anmonia, under pressure. Joannis dissolved NaCl in liquid NH₃ at —10°; on cooling to —30° and letting NH₃ cscape at the ordinary pressure, he obtained slender white needles, probably NaCl.5NH₄ (C. R. 112, 337).—3. Sulphuric anhydride is absorbed by NaCl, forming NaCl.2SO₄, and then perhaps NaCl.4SO₄ (v. Reactions, No. 6).—4. Compounds with sodium iodate are formed, by adding excess of NaCl to NaIO₄Aq, and by boiling NaIO₄ aq was obtained by Ditte, and 3NaCl.2NaIO₄, 18aq by Rammelsberg (P. 44, 548; 115, 584).—5. With many chlorides of less positive metals, e.g. AlCl., CdCl., CfCl., PbCl., MgCl.2 (v. Chlorides of various metals).

Sodium subchloride. H. Rose (P. 120, 15) noticed that a grey-blue solid was produced by fusing NaCl with Na in H; he thought this might be a subchloride of Na. Bunsen and Kirchhoff (P. 113, 339) noticed the formation of a deep-blue substance during the electrolysis of molten RbCl; this substance dissolved in water, giving off H and producing a colourless, strongly alkaline solution; a similar reaction was obtained on electrolysing KCl; these blue substances were regarded by B. a. K. as probably subchlorides, but no analyses or proofs of composition were given.

Bodium, chromisulphocyanide of, v. vol. ii, p. 349.

Sodium, cyanide of, v. vol. ii. p. 347.
Sodium, ferrate of, v. vol. ii. p. 547.
Sodium, ferricyanide of, v. vol. ii. p. 340.
Sodium, ferrite of, v. vol. ii. p. 547.
Sodium, ferrovyanide of, v. vol. ii. p. 337.
Sodium, fluoboride of, v. vol. i. p. 526,

known with certainty, but the formula NaF is

probably molecular.

Formation .- 1. By neutralising HFAq by NaOHAg and evaporating .- 2. Formed along NaOHAq and evaporating.—2. Formed along with NaHSO, by the reaction of HFAq with Na₂SO₄ (Weldon, D. P. J. 182, 228).—3. By fusing together CaF₂, Na₂SO₄, and charcoal, and extracting with water (Jean, C. R. 66, 801, 918).—4. By boiling powdered cryolite with NaOHAq of at least 1.35 S.G. till a little taken out is entirely sol. boiling water, decanting the alkaline liquid from NaF, pressing the NaF. dissolving in boiling water, separating any Al₂O₃ in solution by Na₂SiO₃Aq, removing silica by CO₂, filtering, evaporating, and recrystallising the NaF that separates (Schuch, A. 126, 108) .-5. Berzelius (Lehrbuch [5th ed.] 3, 216) prepared NaF by adding to 100 parts Na2SiF, and 112 parts Na₃CO₃ water enough to make the whole pasty, boiling as long as CO, was given off, extracting the solid thus formed with boiling water, evaporating the solution to dryness, heating the residue gently, again extracting with hot water, filtering from SiO,, and crystal-

Preparation.—Pure Na₂CO₃ (for preparation v. Sobum chlorum, Preparation, p. 477) is dissolved in pure HFAq, till the acid is just saturated, in a Pt dish, the solution is evaporated to dryness, the residue is heated strongly for some time,

and allowed to cool.

Properties.—Clear, lustrous cubes; in presence of Na,CO₃ crystallises in octahedra. Sl. sol. water; S. at 16° = 4.78 (Berzelius), at 15° = 4 (Fremy, A. Ch. [3] 47, 32). Scarcely more sol. hot than cold water. Insol. alcohol. Güntz (A. Ch. [6] 3, 5) gives [NaF,Aq] = -600. Decrepitates on heating, and melts at a high temperature without decomposition (Berzeline)

Reactions.—1. Partially decomposed by heating to redness in water vapour, with formation of NaOH and HF (Weldon).—2. Excess of caustic potash forms NaOHAq.—3. Boiling with magnesia partially decomposes NaF to NaOHAq and forms a double Na-Nig fluoride (MgF2,2NaF) (Tissier, C. R. 56, 848).—4. Completely decomposed to NaCl by heating strongly in hydrochloric acid gas (Deville, C. R. 43, 970).—5. Partially decomposed to NaCl by heating with animonium chloride (Rose, P. 74, 579). Fusion with magnesium chloride produces NaCl and MgF2 (Geuther, J. Z. 2, 208).

Combinations.—1. With several fluorides of less positive metals; 3NaFAIF, occurs native as cryolite (v. Aluminum fluoride, vol. i. p. 145).—2. With silicon fluoride to form Na,SiF, (v. Sodium borate to form 6NaF.Na,B,O, (v. Fluoborates, vol. i. p. 530).—4. With sodium phosphate to form NaF.2Na,PO,. 19aq and 22aq, and NaF.Na,PO,. 24aq (v. Baumgarten, J. 1865. 219; Brieglieb, A. 117, 95).—5. With sodium sulphate to form NaF.Na,SO, (v. Marignac, Ann. M. [5] 12, 18).

SODIUM-HYDDOGEN FLUORIDE NaHF₂ or NaF.HF. This compound is formed, according to Berzelius (*Lehrbuch* [5th ed.] 3, 217), by the spontaneous evaporation of a solution of NaF in HFAq. Forms small rhombohedral crystals,

with a sharp, acid taste. Sl. sol. cold water, more sol. hot water. Decomposed by heat to NaF and HF (Marignac, J. 1857. 128). Güntz (A. Ch. [6] 3, 5) gives [NaF,HF] = 17,100 (to form NaF,HF).

Sodium, hydride of, Na,H. Gay-Lussac and Thénard (A. Ch. 74, 203) observed that Na absorbed H when heated therein. The process was more accurately studied by Troost and Hautefeuille (A. Ch. [5] 2, 273). They found that absorption of H by Na began at c. 300° and ceased at c. 421°, when the gas was at the atmospheric pressure. The product gave, in a Sprengel pump, 237 vols. H. for 1 vol. Na; the formula Na,H requires 238 vols. H. Na,H is a soft, silver-white solid; it can be melted without decomposition in H; S.G. 959. Traces of H are given off at 760 mm. pressure; heated in vucuto a regular dissociation takes place from 330° to 430° (for vapour-pressures of H given off v. Dissociation, vol. ii. p. 398). Moutier (C. R. 79, 1242) gives the thermal value [Na²,H] = 13,000 at c. 330°.

Sodium, hydrosulphide of, NaSH. (Sodium sulphydrate.) Sabatier (A. Ch. 46) 22, 5) obtained this compound by treating Na₂S.9aq with H₂S in absence of air, and then evaporating the liquid so formed in an atmosphere of H₂S. A white, very hygroscopic solid. Passage of CO into NaSHAq drives out H₂S and converts all the Na into Na₂CO₃. NaSHAq contains H₂S and NaOH, according to Gernez (C. R. 64, 86). NaSHAq dissolves S with evolution of H₂S; it ppts. PbS, or MnS, from a neutral solution of a Pb or Mn salt, giving off H₂S; Na₂SAq does not give off H₂S while dissolving S or ppg. PbS or MnS.

Sabatier (l.c.) obtained the hydrate

NaSH.2H.O by passing H.S over Na.S. 9aq, and then evaporating in H.S till half the water was removed; very hygroscopic needles, becoming yellow in air.

Sodium, hydroxide of, NaOH. (Caustic soda Sodium, or sodic, hydrate.) Mol. w. not determined. Melts at 1098° (v. Meyer a. Riddle, B 26, 2443). S.G. 2·13 (Filhol, A. Ch. [3] 21, 415) 1·723 (Smith, Am. J. Pharm. 53, 145). S. (colc water) c. 212 (Bineau, C. R. 41, 509). H.F. [Na,O,H] = 101.870; [Na,O,H,Aq] = 111.810 [Na*O,H*O] = 35,620 (Th. 3, 232).

Formation.—1. By the interaction of Na, of Na, of Na, of Na, of Wa, of with Ha.O.—2. By decomposing Na, CO, Ac with CaO, H2 (v. Preparation, No. 1).—3. By the action of CaO, H2 with NaFAq (Tissier J. pr. 90, 50).—4. By decomposing Na, SO, Ac by BaO or CaO ander pressure.—5. From NaClAq by interaction with PbO (Knab, B 11, 1458).—6. By heating NaNO, with char coal, or with Cu (Wohler, A. 87, 373), or Fe (Polacci, C. N. 26, 288).—7. By decomposing Na, SAq by CuO, Fe,O,, PbO, ZnO, &c. (Kopp D. P. J. 142, 341; Stromeyer, A. 107, 333).—8. By the interaction of NaF and stean (Weldon).—9. By heating soda felspar with lime

Preparation.—1. By causticising soda crystals by lime. A solution of pure Na CO₂ crystal in 4-5 parts water is boiled, in a dish of silve or polished iron, with milk of lime till a littl of the filtered liquid gives off no CO₂ whe acidified; the weight of CaO required is c. the wt. of soda crystals used, it should b

suspended in about as much water as the wt. of soda crystals used; as the boiling proceeds a little water should be added from time to time. otherwise the NaOHAq will decompose some of the CaCO, formed to CaO and Na, CO, Aq. The CaCO, formed is allowed to settle, the vessel being closed, the NaOHAq is drawn off by a siphon and evaporated to dryness in a silver dish, and the residue is heated till volatilisation begins, and allowed to cool in an exsiccator. By dissolving in absolute alcohol, allowing to settle, drawing off the liquid, evaporating it to dryness on a water-bath in a silver dish, removing resinous matter from the warm semisolid mass by a silver spatula, heating to bright redness, and pouring the molten mass on to a plate of polished iron-or, better, of silver-NaOH containing only traces of impurities, chiefly NaCl and Na_xCO₃, is obtained.—2. A large silver dish is surrounded by cold water; 2 or 3 drops of water are placed in the dish, and then a small piece of clean Na, 1 or 2 cms. long; the dish is constantly shaken, so that the Na flows over a large cold surface (explosions are thus avoided); when the reaction is finished 2 or 3 more drops of water are added, and then another piece of Na, while the dish is shaken, and so on. The semi-solid mass is heated till the water is all driven off and the NaOH melts, and the molten substance is poured on to a plate of polished iron or silver.

To obtain NaOH free from nitrites and nitrates Ilosva (Bl. [3] 2, 357) recommends to place Na in water with a layer of petroleum on the surface, the petroleum having been washed with water till free from nitrites and nitrates. He also says that if 2-4 p.o. ordinary NaOHAq is kept for some weeks in contact with granulated Zn all nitrites and nitrates are destroyed.

For preparation of ordinary caustic soda v. Dictionary of Applied Chemistry, vol. iii. p. 480.

Properties.—NaOH is a white, hard, brittle solid. Melts below red heat; volatilises at very bright red heat, higher than temperature of volatilisation of KOH. Very deliquescent; dissolves in c. 47 parts water. During solution in water much heat is produced, [NaOH,Aq] = 9,940 (Th. 3, 232); the maximum amount of heat is produced when H₂O is added to NaOH in the ratio NaOH: 20H₂O, addition of water to this solution is attended with a slight disappearance of heat (Th. 3, 84). (For hydrates v. p. 480, Combinations.) Easily sol. alcohol. NaOHAq with 36:86 p.c. NaOH boils at 130°, with 70 p.c. boils 180°, with 77:5 p.c. boils 238°, with 78:7 p.c. boils 243°, and with 82:6 p.c. boils 260° (Lunge, Soda-industrie, 2, 543).

NaOHAq acts as a strong alkali; its affinity is c. equal to that of KOHAq and LiOHAq and c. 50 times greater than NH, Aq (Ostwald). The properties of NaOHAq closely resemble those of potassium hydroxide solution (q. v. p. 302).

The table in the next column, given by Lunge, shows the composition of NaOHAq of different S.G. at 15°.

Regarding the freezing points of NaOHAq of different concentrations v. Rüdorff (P. 116, 55); de Coppet (A. Ch. [4] 24, 551); and Pickering (who gives very complete data) C. J. 63, 890).

Reactions.—1. According to Deville (C. R. 45, 857), NaOH is decomposed to Na, O, and H by heating to white heat in an iron bottle.—2. Strongly heated with non-volatile acidio anhydrides, water and salts of Na are formed.—3. When molten NaOH is exposed for a considerable time to air or oxygen, some Na,O, is formed (Gay-Lussac; Thénard).—4. Moist or molten NaOH is decomposed by electrolysis, with production of Na (Davy, T. 1802. 1).—5. Heating with sulphur produces polysulphides, sulphite, and sulphate; S heated with NaOHAq forms polysulphides and sulphite. Similar reactions occur by heating with selection or tellurium.—6. Chlorine interacts with NaOHAq is

NaCIO₂Aq is formed. Bromine reacts similarly. If Cl is led into NaOHAq containing iodine in suspension, NaIO₂ is produced.—7. When NaOHAq is warmed with phosphorus, H and inflammable P hydride are given off.—8. Heated with sodium, Na₂O and H are formed.—9. Moist NaOH withdraws carbon dioxide from the air, forming NaHCO₂.—10. Reacts with acids to form Nasalts.—11. NaOHAq ppts metallic hydroxides, or oxides, from solutions of many metallic salts; in some cases the hydroxide dissolves in excess of NaOHAq—e.g. AlO₃H₃, ZnO₂H₂.—12. Molten NaOH acts generally as an oxidiser; e.g. As, Sb, Fe, Pt, &c. form arsenate, antimonate, ferrate, and platinate of Na. Salts are generally decomposed by molten NaOH, giving Na salts, and setting free the bases.—13. According to Schöne (A. 193, 241), addition of hydrogen peroxide to NaOHAq produces Na₂O₂.8H₂O (v. Sodium documpostore, p. 482).

Pickering (priv. comm.) gives the following

P.c. NaOH	S.G. NaClAq at 15° (water at 4° =1)	P.c. NaOH	S.G. NaClAq at 15° (water at 4° =1)	P.c. NaOH	S.G. Na(JAq at 15° (water at 4° =1)

Combinations.—1. With water to form hydrates. The hydrate 2NaOH.7H,O was obtained by Hermes (B. 3, 122) by exposing NaOHAq 8.G. 1365 to the cold of a severe winter; monoclinic crystals, S.G. 1.405, melting it 6°; in vacuo gave off 3H,O. Göttig (B. 20, 543) obtained a dihydrate, NaOH.2H,O, by heating NaOH in 96.8 p.c. alcohol very gradually to 100°. By cooling NaOHAq, Pickering (C. J. 63, 890) obtained the following hydrates, with the freezing-points noted:—

Hydrate	Freezing-poin
NaOH.H.O	- 64·3°
NaOH.2H,O	12.5
NaOH.3-11H,O (sic	c) 2·73
NaOH.3·5H ₂ O	15.55
aNaOH.4H ₂ O	7.57
8NaOH.4H,O	- 1·7
NaOH.5H.O	-12·22
NaOH.7H.O	-23.51

With carbon dioxide to form NaHCO₂.
 Sodium, iodide of, NaI. Mol. w. not known with certainty, but formula NaI is probably Vol. IV.

molecular. Melts at 628° (Carnelley, C. J. 33, 278); at 650° (V. Møyer a. Riddle, B. 26, 2443). S.G. 3.45 (Filhol, A. Ch. [3] 21, 415); 3.654 at 18.2 (Favre a. Valson, C. R. 77, 579). S.H. (26° to 50°) 0881 (Schuler, P. 136, 70); (16° to 99°) 08684 (Regnault, A. Ch. [3] 1, 129). Kremers (P. 108, 120) gives the following data for solubility in water;—

Temp.	s.	Temp.	8.
0°	158.7	- 80°	303
20	178.6	100	312.5
40	208.4	120	322.5
60	$256 \cdot 4$	140	333.3

S. = $264 \cdot 19 + \cdot 3978t$, when t varies from $64 \cdot 7^{\circ}$ to $138 \cdot 7^{\circ}$ (de Coppet, A. Cl_{l} . [5] 30, 411). Gerlach (Fr. 8, 285) gives following:—

S.G. NaIAq	P.C. NaI	S.G. NaIAq	P.C. Nal
1.04	5	1.36	35
1.082	10	1.432	40
1.128	12	1.51	45
1.179	20	1.6	50
1.234	25	1.7	55
1.294	80	1.81	60

Easily sol. alcohol. Saturated NaIAq boils at 1411°. H.F. [Na,I] = 69,080; [Na,I,Aq] = 70,800 (Th. 3, 232).

Formation.—1. When Na and I are fused together only very small quantities combine (Merz a. Weith, B. 6, 1518).—2. By decomposing BaI.Aq, or Cal.Aq, by Na.CO₃ or Na.SO₄, filtering, and evaporating.—3. By neutralising HIAq by Na.CO₃, and evaporating.—4. I is added to water and iron filings till the iron is almost all dissolved, the solution is filtered, and Na.CO₃ is added so long as FeCO₂ ppts.; the liquid is filtered (if alkaline it is neutralised by HIAq) and evaporated, any Fe.O₃ which separates being filtered off (Baup, J. Ph. 9, 37, 122).

Preparation .- 1. Iodine is added to moderately conc. NaOHAq till a yellow colour is produced; finely-powdered charcoal, equal to c. 100 of the weight of I used, is added; the liquid is evaporated to dryness and the residue is heated in a covered crucible to dull redness for some time; when cold, the residue is dissolved in water, the liquid is filtered (neutralised by HIAq if alkaline) and crystallised at 40°-50°. (For more details v. Potassium iodide, Preparation, p. 304.)-2. A quantity of NaOHAq is divided into two equal portions; I is added to one part till a yellow colour remains, an equal quantity of I is then added, and then the other portion of NaOHAq is saturated with SO₂ and added, and the whole is evaporated till NaI crystallises out; the salt is purified by recrystallisation from water at 40°-50° (Stephani, J. Ph. [3] 26, 450).

Properties.—Crystallises from aqueous solutions at 40° to 50° in cubes (Mitscherlich, P. 17, 385); the hydrate NaI. 2aq separates at ordinary temperatures. Melts at 629°; volatilises less readily than KI, but at a lower temperature than NaCl (Mohr, A. 21, 66). Deliquesces in moist air, becoming rose-coloured with separation of some I and formation of some Na₂CO₃ (Girsult, J. Ph. 27, 390).

Reactions and Combinations.—1. Heated in air some I is separated and O absorbed, and the reaction becomes alkaline (Berzelius, Lehrbuch

11

[5th ed.] 3, 215).-2. Heated with charcoal in ! contact with air much Na CO is formed (Girault, l.c.). Most of the reactions of NaI are similar to those of KI (v. Potassium iodide, Reactions,

p. 304).

Combines with most iodides of less positive metals. Forms a compound with arsenious oxide NaI.As,O. (Rüdorff, B. 21, 3051). The dihydrate NaI.2H,O crystallises at the ordinary temperature from NaIAq in large monoclinic prisms; S.G. 2.448; melting at c. 65° and giving NaI; effloresces in dry air, and deliquesces in moist air.

Sodium, manganicyanide of, v. vol. ii. p.

Sodium, manganocyanide of, v. vol. ii. p. 842.

Sodium, nitride of, Na, N. A dark-grey solid; formed by heating NaNH, (v. Sodium AMIDE, p. 475) to redness in absence of O. Resembles potassium nitride (q. v., p. 304) (Gay-Lussac a. Thénard, A. Ch. 65, 325).

Sodium, nitroprusside of, v. vol. ii. p. 341. Sodium, oxides of. Two oxides have been isolated, Na₂O and Na₂O₂.

Sodium oxide Na₂O. (Sodium monoxide.) It is doubtful whether this compound has been obtained pure. Davy (T. 1808. 24) said that when Na is fused with dry soda there is 'a division of the oxygen between the alkali and the sodium.' Na does not combine with O when exposed to quite dry air at the ordinary temperature (von Bonsdorff, P. 41, 296). According to Beketoff (v. B. 12, 856; 16, 1854), NaOH and Na do not react at a red heat. Beketoff (J. R. 1883. [i.] 277 [v. B. 16, 1854]) allowed Na to drop into a red-hot copper cylinder, then passed in a mixture of 1 vol. O and 4 vols. air, and heated by a blowpipe; in this way he obtained Na,O, but always mixed with some Cu and traces of Na; considering the conditions under which Na, O, is obtained (v. infra, Sodium dioxide) it is likely that B.'s Na₂O contained Na₂O₂.

Na O is described as a greyish solid; Beketoff's preparation was rose-coloured, but it contained Cu. Na₂O dissolves in water to form NaOHAq; B. gives [Na²O,Aq] = 55,500; and from this and other data Thomsen (Th. 3, 232) calculates [Na2,O] = 99,760. According to B. (l.c.), hot Na2O reacts with H to form NaOH and Na; heated to c. 300° in CO it gives Na₂CO₃ and Na (B., lc.). Combination with CO₂, to form Na₂CO₃, occurs at c. 400°. By heating Na amalgam with HgO, B. (l.c.) obtained the compound Na₂HgO₂ = Na₂O.HgO. Comey and Jackson (B. 21, 1589; Am. 11, 145) describe various compounds of Na₂O with ZnO and H₂O.

SODIUM DIOXIDE Na₂O₂. (Sodium peroxide.) The formation of an oxide with more O than Na₂O, by heating Na in air, was noticed by Gay-Lussac a. Thénard (A. Ch. 65, 325). Pure Na₂O₂ was obtained by Vernon Harcourt (C. J. 14, 267) by heating Na, in a flask of hard glass filled with N, till the Na melted, then sending in a slow stream of dry air, and heating till the metal was changed to a yellowish-white solid, and heating this for some time in dry O. Na₂O₂ is a white solid, becoming yellowish on heating. It deliquesces gradually in air, and then is gradu-

with production of much heat; on heating O is evolved; Na,O,Aq deposits crystals of the hydrate Na₂O₂, Aq deposits crystals of the nyarate Na₂O₂, 8H₂O on standing over H₂SO₄ (v. infra, Hydrates). Na₂O₂ acts as an energetic oxidiser when heated; C, I, P, S, Sn are oxidised, more or less rapidly; heated with CO, Na₂CO₃ is formed; with N₂O the products are NaNO₂ and

N (v. Harcourt, l.c.).

Hydrates of sodium dioxide. The octohydrate, Na₂O₂8H₂O, was obtained by Harcourt (l.c.) by evaporating a solution of Na.O. in water over H_2SO_4 . Fairley (C. J. [2] 16, 125) obtained the same hydrate by adding H_2O_2Aq to NaOHAq and ppg. by alcohol. Schöne (A. 193, 241) also obtained the octohydrate by the action of H2O2Aq on NaOHAq, evaporating in vacuo, drying on a porous tile, washing with 90 p.c. alcohol, and drying between filter paper. By using a considerable excess of H,O,Aq, Schöne (l.c.) obtained crystals to which he gave the composition Na₂H₁O₈·4H₂O = Na₂O₂·2H₂O₂·4H₂O₃ on drying over H₂SO₄, Na₂O₂·2H₂O₄ remained. The dihydrate Na₂O₂·2H₂O is obtained by drying the octohydrate for some time over H2SO4.

Sodium, phosphide of. A compound of Na and P was supposed by Gay-Lussac a. Thénard, and also by Davy, to be formed by heating the elements together in N. Vigier (Bl. [2] 3, 7) recommends to place a piece of Na in rock oil, boiling at c. 120°, in a retort, to add P little by little (much heat is produced and some oil distils) till there is an excess and some crystallises on the cold parts of the retort, to distil off the oil from the black phosphide formed, to wash with CS2, and dry in a stream of CO2.

The phosphide may be kept in dry air; in moist air, water, or acids it gives off inflammable P hydride (v. also Lüpke, C. C. 1890. [ii.]

Bunsen (A. 138, 292) obtained a phosphide of Na by strongly heating a mixture of Na, HPO. and Na in a narrow glass tube.

Sodium, platinocyanide of, v. vol. ii. p. 344. Sodium, platinosulphocyanide of, v. vol. ii. p. 351.

Sodium, salts of. Compounds formed by replacing H of acids by Na. These compounds belong to the type NaX where X is a monovalent acidic radicle. The chief salts of Na derived from oxyacids are antimonate, arsenate, bromate and hypobromite, carbonates, chlorate, perchlorate, chlorite and hypochlorite, chromate and dichromate, ivdate and periodates. manganate and permanganate, molybdates, nitrate and nitrite, phosphates, phosphites and hypophosphite, selenates and selenites, silicates, sulphates, sulphites, thiosulphate and thionates. tellurates and tellurites (v. CARBONATES, NITRATES, Sulphates, &c.).

Sodium, selenides of. Two selenides have been isolated, Na₂Se and Na₂Se₂, corresponding with two of the sulphides and with the two oxides.

Sodium monoselenide Na.Se. Obtained by mixing well-cleaned Na rubbed to powder with the proper proportion of Se (Rosenfeld, B. 24, 1658). Uelsmann (A. 116, 127) says Na, Se is obtained, in large colourless crystals, by saturating NaOHAq with H₂Se, then heating in a stream of H and allowing to cool; it seems probable ally changed into solid Na, CO. Soluble water, that these crystals were a hydrate of Na, Se (v.

infral. Fabre (U. H. 102, 613) obtained Na, Se by heating 2Na,Se.9H.O (v. infra, Hydrates) in a current of N to not above 400°; F. describes Na Se as a hard, white, crystalline, deliquescent solid, becoming reddish-brown when fused; owing to its action on glass, F. did not get Na Se free from silica and alumina.

Hydrates of sodium monoselenide. By passing a rapid stream of H.Se into NaOHAq (1 part NaOH in 4 water) Fabre (l.c.) obtained Na Se.16H O, melting at 40°, giving Na₂CO₃, a little Na₂SeO₃, and Se on exposure to air. By using more conc. NaOHAq (3:1), and keeping the temperature down, F. obtained Na₂Se.9H₂O; and when very conc. NaOHAq was used, he obtained 2Na Se.9H2O.

For data regarding heats of formation of Na.Se and hydrates, v. Fabre, C. R. 102, 703.

Sodium diselenide Na2Sc2. Wöhler and Dean (A. 97, 1) obtained a selenide of K by heating K2ScO3 with charcoal; Rathke (A. 152, 211) showed that the selenide was K.Se., and Jackson (B. 7, 1277) using Na, SeO, and charcoal obtained the corresponding selenide of sodium.

Sodium, seleno-antimonate of, v. vol. i. p. 286.

Sodium, selenocyanide of, v. vol. ii. p. 348. Sodium, silicofluoride of, Na SiF . Prepared by adding H2SiF6Aq to conc. NaClAq, washing, and drying. Gelatinous when ppd., but becomes crystalline on drying. S.G. 2.7517 at 17.5° (Stolba, Fr. 11, 199). S. 65 at 17.5°; 2.46 at 100° (S., l.c.). Insol. alcohol. Melts at red heat, giving off SiF, (Berzelius).

Sodium, sulphides of. Several compounds of Na and S exist, but there is considerable doubt as to the compositions of some of the substances that are described as definite sul-

phides of Na.

Sodium monosulphide Na,S. Obtained by passing H2S over dry NaOH, the heat produced suffices to remove H₂O formed (Kircher, A. 31, 839). Rosenfeld (B. 24, 1658) says that Na₂S is formed when 1 part thoroughly clean Na is rubbed to powder and mixed with 3 parts NaCl and 7 part S; the combination is sudden, and light is produced; pressure must be avoided in mixing the substances. By heating 100 to 105 parts Na SO, with 20 parts charcoal, a fleshcoloured mass of Na,S with some C is obtained: the reduction may also be effected in H. By dissolving the product of reduction in water and crystallising, the hydrate Na₂S.9H₂O is obtained; by dissolving the crystals again, heating with Cu (to decompose polysulphides), and evaporating to dryness in a stream of H, Na₂S remains (Priwoznik, A. 164, 69).

Na,S is also obtained, fairly pure, by gently heating Na₂S.9H₂O in a stream of H (Weyl, P. 123, 362; cf. Sabatier, A. Ch. [5] 22, 5).

Na S is an amorphous, flesh-coloured, deliquescent solid, with a strongly alkaline reaction; easily sol. water, solution being colourless if polysulphides are quite absent. According to Weldon (v. Lunge's Soda-industrie, 2, 311), Na₂S is not fusible if it be quite free from polysulphides, thiosulphate, and NaOH.

Na SAq becomes yellow in moist air from formation of polysulphides (Kolb, A. Ch. [4] 10, 106); when air is blown into Na SAq, NaOH

and Na,S,O, are formed, and then Na,SO, (Lunge, l.c., p. 531). Na,S is decomposed by acids, even by CO₂, with evolution of H₂S (v. Stromeyer, A. 107, 372). Heating Na₂SAq with NaHCO₃ or NH₄.H.CO₃ produces complete decomposition to Na₂CO₃ (Lunge, *l.c.* p. 800). Boiling with AlO₃H₃, or heating Na₂S with Al₂O₃, forms Na aluminate (v. W. J. 1863. 713; 1865. 332). CaO is said not to decompose Na₂SAq (v. Kolb, A. Ch. [4] 10, 106). Several metallic oxides decompose Na SAq, forming NaOHAq, sometimes (e.g. with CuO) Na S.O. Aq is also formed. Na.S combines with various metallic sulphides (v. Schneider, P. 138, 302; 151, 446; Völcker, A. 59, 35; Berthier, A. Ch. [2] 22, 245).

Hydrates of sodium monosulphide.

The hydrates Na.S.9H.O, Na.S.10H.O, and

Na S.5H,O have been formed. The hydrate with 9H₂O is most easily obtained by saturating one half of a solution of NaOH with H.S. adding the other half, and evaporating, when large colourless crystals separate (Rammelsberg, P. 128, 172); S.G. 2471 (Filhol, A. Ch. [4] 28, The pentahydrate is formed similarly to the hydrate with 9H₂O, but using alcoholic in place of aqueous NaOH (Böttger, A. 223, 335; v. also Finger, P. 128, 635; Lemoine, C. R. 98, 45). For the preparation of Na.S.10H₂O v. Damoiscau (C. C. 1885. 36). Göttig (J. pr. [2] 34, 229) by partially saturating NaOH in alcohol

with H₂S got hydrates with 5, 5¹₂, and 6 H₂O.
Sodium disulphide Na₂S₂. This compound is supposed by Sabatier (A.Ch. [5] 22, 5) to exist in the solution obtained by heating Na SAq with solution of polysulphides formed by digesting Na₂SAq with S. Böttger (A. 223, 335) obtained the hydrate Na₂S₂.5H₂O by dissolving S in an alcoholic solution of Na,S.

Sodium Trisulphide Na2S3 is formed, according to Schöne (J. 1867. 190), mixed with Na₂SO₄, by strongly heating Na₂CO₃ with excess of S (cf. Sabatier, l.c.). For the hydrate Na₂S₈.3H₂O v. Böttger (l.c.).

Sodium Tetrasulphide Na,S, is said to be obtained by heating Na,S, (Chapman Jones, C. J. 37, 461; ef. Sabatier, l.c.). For hydrates v. Schöne (P. 131, 380) and Böttger (l.c.).

The existence of a pentasulphide is doubtful (v. Schöne, l.c.; Sabatier, l.c.; Geuther, A. 226,

232; Chapman Jones, l.c.).

Soda liver of sulphur. This name is given to the brown solid obtained by heating S with Na₂CO₃ in a closed vessel; it contains various • sulphides of Na, along with Na, S,O,, Na, SO, and generally some Na₂CO₃.

Sodium, sulphocyanide of, v. vol. ii. p. 352. Sodium, sulphydrate of, v. Sodium Hydrosulphide, p. 479.

Sodium, telluride of. According to Rosenfeld (B. 24, 1658), well-cleaned Na in powder readily combines with Te.

Sodium, thio-arsenates and thio-arsenites of, v. vol. i. pp. 316, 317. Sodium, thio-carbonate of, v. vol. i. p. 703.

M. M. P. M.

SODIUM ETHIDE NaC2H3. This compound is not known in the free state. Sodium dissolves in cold ZnEt2, separating zinc. The solution, cooled to 0°, deposits ZnEt2NaEt in trimetric tables [27°], sol. benzene, and decomposed by water. CO₃ acting on ZnEt,NaEt forms sodium propionate (Wanklyn, A. 107, 125; 108, 67). Etl attacks ZnEt, NaEt, forming ethane and C₂H₄ (Frankland, A. 110, 107). Sodium methide may be obtained in like manner

(Wanklyn, A. 111, 234).

80JA OIL. The oil from Soja hispida contains tripalmitin and tristcarin (Meisel a. Böcker, M. 4. 365).

80LANINE C₅₂H₅₃NO₁₈ (?) (Firbas, M. 10, 541); C₁₂H₃₁NO₁₈; C₁₂H₃₁NO₁₅ (Hilger, A. 195, 317); C₂₁H₃₂NO, (Kletzinsky, Z. [2] 2, 127). [244²]. Occurs in the berries of the deadly nightshade (Solanum nigrum) (Desfosses, J. Ph. 6, 374), in berries of S. verbascifolium (Payen a. Chevallier, J. Chim. Med. 1, 517), in small quantity in the tubers and green parts of the potato (S. tuberosum), in the shoots of sprouting potatoes (Baup, A. Ch. [2] 31, 109; Otto, A. 7, 150; 26, 232), to the extent of 03 p.c. in diseased potatoes (Kassner, Ar. Ph. [3] 25, 402). in the flowers, stalks, and berries of the woody nightshade (S. Dulcamara), and in the root of

Scopolia japonica (Martin, Ar. Ph. [3] 13, 336).

Preparation.—1. The berries are pressed, the juice ppd. by ammonia, and the pp. recrystallised from alcohol.—2. Fresh potato sprouts (200 kilos.) are digested with 2 p.c. acetic acid; the filtrate is ppd. by ammonia; and the pp. extracted with boiling 85 p.c. alcohol. To the hot alcoholic filtrate NH₁Aq is added until turbidity appears. On cooling, a mixture (125 g.) of solanine and solanein is de-posited. These bases are separated by fractional crystallisation from hotspirit (Firbas; cf. Reuling, A. 80, 225; Zwenger a. Kind, A. 109, 244; 118, 129; Kromayer, Ar. Ph. [2] 116, 114; Missaghi,

B. 9, 83; Gmelin, A. 110, 167). Properties.- Colourless needles, v. sol. hot 85 p.c. alcohol, insol. CHCl, and ligroin, sol. HClAq, almost insol, water and ether. The crystals are $C_{52}H_{es}NO_{16}4_{2}^{1}$ nq (Firbas). Poisonous. Not affected by alcoholic potash. Sublimes at 190° (Blyth). Gives an orange colour with I and H.SO.. On heating with 2 p.c. with I and H.SO. On heating with 2 p.c. HClAq it yields solanidine and a dextrorotatory sugar that reduces Febling's solution, [a]_D = 28.6°, yields with phenyl hydrazine an osazone [199°], and is oxidised by HNO, to mucic and saccharic acids; levulose is not present. Solanine colours a mixture of alcohol and H,SO, rose red. With ammonium selenite (1 g.) in conc. H₂SO₄ (20 c.c.) it gives a canaryyellow colour turning to brown, and, after three nours, to violet-red (Ferreira da Silva, Bl. [3] 6, 87; C. R. 112, 1267). A solution of ammonium vanadate in H2SO, is coloured brown by dry solanine, the colour becoming red, and finally disappearing on dilution (Mandelin).

Salts.—C, H, NO, HCl. Got by adding ether to an alcoholic solution of the base and HCl. Gelatinous pp. which dries up to a gummy mass.—B'₂H₂PtCl₄: yellow flocculent By H.Q.Q.7aq; crystalline crusts.

Acetyl derivative C., H., A.Q.NO,. Needles

(from ether), insol. water (Hilger).

Solane'in C₁₅H_{ss}NO₁₅ 4aq. [208°]. Obtained as above (Firbas). Amorphous. More sol. 85 p.c. alcohol than solanine. Decomposed by HClAq into the same products as solanine. Colours Mandelin's reagent red,

Solanidine C. H. NO. [191°]. Formed as above. Colourless needles (from ether). Affects Mandelin's reagent in the same way as solanin Ac.O at 140° gives a diacetyl derivative (Firbas). Converted by fuming HClAq in the cold into amorphous yellow solanioine C₂₂H₂₂NO (?), which yields B'HCl and B'₂H₂PtCl_e (Zwenger, A. 123, 341).

Salts.—B's(HCl), aq: crystalline powder.—

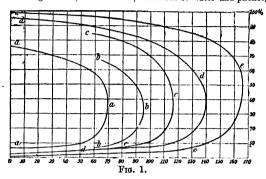

B',4H,SO,8aq: colourless plates [247°].
SOLUTIONS. Inasmuch as many of the questions connected with the state of bodies in solution are not yet fully elucidated, and inasmuch as two very different conceptions are put forward regarding the compositions of bodies present in aqueous solutions of salts, the editor of that portion of the Dictionary to which the subject of solutions belongs thought it advisable to ask the originator of the electrolytic dissociation hypothesis of saline solutions to write a short article on solutions in general, and to invite one of the leading upholders of the hydrate hypothesis of saline solutions to summarise the arguments in support of that hypothesis.

SOLUTIONS I. A solution is a homogeneous mixture of two or more bodies in the liquid state. A distinction is made between the dissolved substance and the solvent; the substance present in greater quantity is generally spoken of as the solvent. In some cases the solvent is taken to be the substance with the lower temperature of solidification. In the cases of substances miscible in all proportions—a mixture, for instance, of equal parts of alcohol and water -there is no way of determining which should be regarded as the solvent and which as the dissolved substance. There are many instances of two bodies that cannot be mixed in all and any proportions; the solubility of such bodies is said to be limited. If the 'dissolved body' in such a case is present in excess, either as gas, liquid, or solid, a condition of equilibrium is finally attained wherein the solution can take up no more of the dissolved body as long as the external conditions (temperature and pressure) remain unchanged; such a solution is said to be saturated. The attainment of saturation is hastened by shaking.

Saturated solutions of gases. When a gas is placed over a liquid, such as water or alcohol, a portion of the gas dissolves in the liquid. There is a constant relation at constant temperature between the quantity of gas remaining per unit volume and the quantity dissolved by the liquid per unit volume (Henry's law). Inasmuch as the quantity of the gas, per unit volume, is proportional to the partial pressure of the gas, the law may be stated by saying that the quantity of the gas dissolved in the liquid is proportional to the partial pressure of the gas above the liquid. As all the gases that have been examined dissolve with production of considerable quantities of heat, the solubilities of these gases decrease as temperature increases, in accordance with the second law of thermodynamics. The measurements made by Bunsen (Gasom. Methoden [Braunschweig, 1877]) show that the solubilities of some gases are independent of temperaturefor instance, the solubility of H in water and of O and CO in alcohol. Henry's law holds good, as indicated by theory, only so long as the quantity of the gas per unit volume, both undissolved

and in solution, is small, and the molecules of the dissolved and the undissolved gas are of equal magnitude. Van't Hoff has made use of the law of Henry to prove the equality of the molecules of the same gas in the gaseous state and in dilute solution (Z. P. C. 1, 489 [1877]). When NH, HCl, and SO, are dissolved in water in large quantities these gases do not follow the

temperature, which corresponds to the critical temperature for the liquids, is passed, the two liquids dissolve in all proportions. This behaviour has been more fully examined by Alexe-jeff (W. 28, 305 [1886]) and has been represented by him in curves, some of which are reproduced here (fig. 1). The curve a represents the behaviour of water and phenol, b that of water

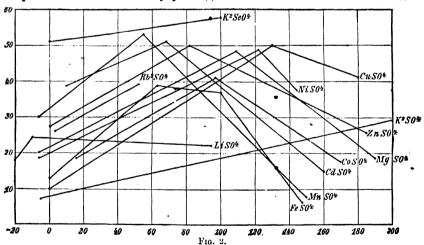

law of Henry; neither does the law hold good for solutions of acetic acid in benzene or ether in water, because the molecular magnitudes of these compounds are not the same in the gaseous state and in solution, as is proved by determinations of the boiling-points of the compounds in question (Nernst, Z. P. C. 7, 97 [1891]).

Mutual solutions of liquids. When two

liquids that are not miscible in all proportions,

and salicylic acid, c that of water and benzoic acid, d that of water and aniline phenolate, and e that of water and aniline. The abscissm represent temperature, and the ordinates percentages of the dissolved substances in the solutions. To each temperature correspond two points in the curve showing the percentage composition of the solution of the substance in water, and that of the solution of water in the molten sub-

such as other and water, are shaken together, two layers are formed, one floating on the other; one of these contains much water and little ether, while the other contains much ether and little The compositions of the two layers water. change with change of temperature. Generally speaking, the compositions become more alike as temperature rises, until a temperature is reached whereat they are identical; when this

stance; thus, for phenol and water (curve a), at 20°, the solutions are composed of 92°5 p.c. water and 7°5 p.c. phenol, and 28 p.c. water and 72 p.c. phenol respectively. The two liquids are miscible in all proportions above 69°

It happens sometimes that two liquids are miscible in all proportions below a certain temperature, but form two layers above this temperature; in such cases—for example, in the solution of di-ethylamine in water-the convexity | add a tl of the curve is turned to the left.

Saturated solutions of solids. Most of the measurements that have been made deal with solutions of salts in water. The example of Gay-Lussac has generally been followed, and the solubility of the salt has been taken as the weight thereof dissolved by 100 parts by weight of the solvent. Etard and Engel have given solubility-curves for very large variations of temperature (C. R. 98, 993, 1276, 1432; 104, 1614; 106, 206, 740 [1884-88]). Some of these results are shown in fig. 2, p. 485; the abscissæ represent temperature and the ordinates parts by weight of the salts in 100 parts of the solution (not in 100 parts of the solvent). The change of solubility with change of temperature depends on whether the process of solution is accompanied by disappearance or production of heat; in the former case solubility increases, in the latter case it decreases, as temperature rises. Inasmuch as different hydrates of the same salt are dissolved with the production of different quantities of heat, these hydrates give different solubility-curves. Sodium sulphate is the salt that has been most carefully examined in this respect. The hydrate Na₂SO₄.10H₂O, that exists up to 33°, dissolves in water with disappearance of heat; hence the solubility of this hydrate increases as temperature increases. On the other hand, Na₂SO₄, stable above 33°, dissolves with production of heat, and its solubility decreases with increasing temperature. The so-called curve of the solubility of sodium sulphate consists, therefore, of two parts, one rising till the temperature reaches 33°, and one falling above that temperature. Looked at accurately, the first part of the solubility-curve holds good only for Na₂SO₄.10H₂O₅ and the second part only for Na SO. For the solubility of a chemical compound is determined only when the composition of the solid compound that is in contact with the solution is definitely stated. The compound CaSO, is considerably more soluble than the crystalline hydrate CaSO, 2H,O. The measurements made by Etard show that many other sulphates -MnSO. and CdSO, for instance-behave similarly to Na₂SO, (see fig. 2).

The solubilities of most salts increase as temperature rises; the solubility of NaCl varies very little with temperature. The solubilities of many compounds of calcium decrease with increasing temperature, e.q. hydroxide, acetate, isovalerate, isobutyrate, succinate, and iso-succinate of calcium. Barium succinate and SrSO, behave similarly, but not the other corresponding salts of Ba and Sr. Some calcium salts show maximum solubilities at certain temperatures-e.g. CaSO, 2H,O at 35°; others show minimum solubilities -e.g. propionate at c. 55°, isobutyrate at 65°, also normal butyrate, valerate, iso-octoate, citrate, and benzoate (Allen, C. N. 57, 236 [1888]). Attempts have been made to express the connection between the solubilities of salts and temperature by a formula. The following expression holds good in many cases: S = a + bt (t =temperature, and a and b are constants); i.e. solubility changes linearly with temperature-for instance, for KCl, BaCl, NaNO, and several sulphates, especially at high temperation absence of these (Barus a. Schneider, Z. P. C. tures (Étard). In other cases it is necessary to 8, 291 [1891].) Colloidal substances having

a serm, and so scops the formula $S=a+bt+ct^2+dt^2$ (c and d are constants as well as a and b). The formula log. $S = a + bt + \dots + \dots$ often gives a better representation with a smaller number of coefficients.

Supersaturated solutions. When a salt whose solubility increases with temperature is dissolved at a high temperature in water (or other solvent), and the solution is cooled, a temperature is reached whereat the solution is saturated with reference to a definite hydrate of the solid salt: but if the solution is further cooled salt does not separate, provided there is no crystal of the hydrate in question in contact with the solution. Such a solution is said to be supersaturated. A solution may be supersaturated with reference to one hydrate, but not supersaturated with reference to another hydrate. For example, Na₂SO₄.7H₂O is more soluble in water than Na, SO, 10H,O, and so a solution may be obtained, by dissolving Na.SO,, that is supersaturated as regards the decahydrate but not as regards the heptahydrate; that is to say, if a crystal of Na₂SO₄.10H₂O is brought into the solution, at a certain temperature, the decahydrate crystallises out, but at the same time the solution is able to dissolve the hydrate with 7H,O. If temperature falls again the solution, of course, becomes supersaturated with reference to both the hydrates.

At one time the supposition was often held that the dissolved substances were present in supersaturated solutions in a state different from that in which they existed in ordinary solutions. More accurate investigations of the physical properties on both sides of the point of saturation have shown that there is no essential difference between the solution before and after saturation, but that the relation of a supersaturated to a saturated solution is exactly the same as that of a saturated solution to the solution before saturation.

Colloidal solutions. Certain substances, such as gelatin, absorb unlimited quantities of water and become swollen thereby; when much water has been taken up, liquids are formed which do not part with the dissolved body on cooling, as ordinary solutions do, but set to jellylike substances. All compounds that form colloidal solutions have very large molecular weights; such compounds are acids of Mo, Si, Sn, Ti, and W; oxides of Sb, Fe, and Mn; sulphides of Sb, As, Bi, Cd, Co, Au, Fe, Pb, Hg, Ni, Pd, Pt, Ag, Tl, and W; many organic substances, such as caramel, dextrin, eggalbumen, tannin, &c.; and also some elements, such as Se and Ag. Some of these solutions are characterised by the fact that the addition of small quantities of foreign substances-as salts, acids, and bases-causes coagulation, whereupon the bodies in the colloidal solutions become insoluble. For that reason it is generally supposed that colloidal solutions are intermediate between emulsions and true solutions. Emulsions -e.q. a fine deposit of alumina-possess the special property that the emulsionised bodies are thrown down much more quickly in presence of electrolytes, and also of other foreign substances, than

molecular weights under 30,000—gelatin or gum, for instance—are characterised by the fact that if their solutions are solidified by cooling they again become liquid and transparent when heated. Colloids having molecular weights greater than 30,000 do not share in this property, but behave, in this respect, like very supersaturated solutions (Sabanejeff, J. R. 1891. [1] 80; Z. P. C. 9, 89 [1892]). When colloids take up water, and swell but do not dissolve, heat is produced; when they dissolve heat disappears (Wiedemann a. Lüdeking, W. 25, 145 [1885]).

Reasons for assuming the existence of hydrates in solutions. When a dissolved substance is isolated, by various methods, from its solvent the solid generally separates in combination with water of crystallisation. It has, therefore, been generally supposed that a pre-ponderating quantity of this hydrate must be present in the solution. This conclusion is not, however, tenable; for if only a minimum quantity of the compound that separates out were present in the solution this might suffice to cause the separation. The following consideration has been brought forward as an argument in favour of the existence of hydrates in solutions. A solution of 57 parts by weight HI and 43 parts water boils at 127°, and the distillate has the same composition as the residue; this lends some countenance to the view that this mixture behaves like a definite chemical compound. On adding water to this solution and distilling a more dilute acid at first passes over, and at last the acid with 57 p.c. HI distils off. If the solution contains more than 57 p.c. HI to begin with, the distillate at first contains a more conc. acid, and, later, acid of 57 p.c. This behaviour is simply explained in the following way. A solution of 57 p.c. HI possesses a minimum vapourpressure, so that both less dilute and more dilute solutions at the same temperature have larger VADOUR-PRESSURES. Speaking generally, the vapour from a solution does not contain both components in the same proportion as the solution itself. In the case under consideration the vapours from the more dilute solutions contain more water (in proportion to HI) than the solutions, and the vapours from the less dilute solutions contain, relatively, more HI. The dilute solutions increase in concentration as distillation proceeds, the boiling-point rises, and there is at last produced the 57 p.c. solution which possesses the lowest vapour-pressure at an equal temperature—i.e. the highest b.p. (127°) at an equal pressure. If, on the other hand, distillation is commenced with a more concentrated solution proportionally more HI passes over, and an approach is gradually made, from the other side, to the solution with highest b.p. There is, therefore, no binding reason for regarding this solution as a definite chemical compound. For, indeed, the composition of the solution changes according to the pressure under which the distillation is conducted; and this could not well be the case were the solution really a definite chemical compound.

In investigating the freezing-points and vapour-pressures of solutions it was found that in many cases the deviation from the freezing-point and vapour-prossure of the pure solvent

was proportional to the quantity of substance (salt) in solution. But in other cases this proportionality seemed not to be maintained unless the supposition were made that a portion of the water had combined with the dissolved substance (Wüllner, P. 103, 529; 105, 85; 110, 564 [1858, 1860]; de Coppet, A. Ch. [4] 23, 366; 25, 502; 26, 98 [1871-2]; Rüdorff, P. 114, 63; 116, 59 [1861-2]; 145, 599 [1870]). It was, therefore, supposed that such compounds as HI, HCl, BaCl, CaCl, NaBr, &c., were combined in aqueous solutions with definite quantities of water of crystallisation. But the recently-discovered laws which express these phenomena lead to very different methods of explanation, so that the conclusion that these compounds exist as hydrates in solutions seems, in this respect, to be entirely without foundation.

Mendeléeff not long ago examined the changes in the S.G., accompanying changes in the composition, of aqueous solutions of alcohol and of sulphuric acid (Z. P. C. 1, 273 [1887]); he thought he had found abrupt irregularities in the changes of S.G. He supposed, without any theoretical foundation, that at the concentrations whereat these occurred the solutions corresponded to perfectly definite hydrates. Pickering (Z. P. C. 6, 10 [1890]) showed, as the result of more accurate investigations, that Mendeléeff's conclusions rested on inaccurate observations. Pickering, however, accepted Mendeléeff's idea, and supposed that the higher derivatives of the S.G. in reference to percentage composition showed similar irregularities. He treated the freezing-points and the electrical conductivities of solutions in the same way, and he supposed that in all these cases he had discovered such irregularities as indicated the existence of definite hydrates. It is absolutely impossible to reconcile the numbers for the electrical conductivities of dilute solutions of acids and bases (e.g. for acetic acid) with Pickering's views; nor do the most recent investigations on the freezing-points of very dilute saline solutions (Jones, Z. P. C. 11, 534; 12, 623 [1893]) in any way agree with these views. Moreover, the method used by Pickering is not free from objection under any conditions.

From an extended and systematic investigation recently made into the constitution of ammoniacal metallic compounds, and compounds analogous therewith, Werner (Zeit. f. anorg. Chem. 3, 267 [1893]) concluded that in electrolytically conducting salt solutions the metallic atoms of the salts might be expected to be generally accompanied by six molecules of water, and that those salts which readily combine with water of crystallisation would be the best conductors. This statement is not, however, in any way in keeping with the experimental results. The salts of ammonium, K, Rb, and Cs conduct better than any others that have been examined; after these come the salts of Na. Li, and the metals of the earths; and then, much behind these, come the salts of the heavy metals; but water of crystallisation combines most readily with the salts last mentioned. and least readily with those mentioned first.

Conclusions regarding the existence of hydrates of substances in solution have also been drawn from the results of investigations of other u properties, such as contraction or , or production of heat, during solution,

osity, &c. general, it has been supposed that where

properties exhibited a maximum or minior other purely mathematical characterhere existed a definite hydrate of corresponding composition. Attention may, however, be called to the fact that these points generally shift with changes of temperature, so that the hypothetical hydrate must have a different, and constantly changing, composition at different temperatures—a conclusion which is not in keeping with the representation of the hydrate as a

definite chemical compound.

It is, indeed, in the highest degree likely that when definite hydrates separate from a solution the same hydrates were previously present in the solution, perhaps only in small quantity; but we have as yet no accurate knowledge as to the magnitude of the quantity. The methods that have been used in investigating this most interesting question have scarcely brought to light a single new result, although many and renowned investigators have carried out a very large amount of work in this direction.

The solubility of a salt, at constant temperature, is to a small extent dependent on pressure. Sorby was the first to carry out detailed investigations on this subject (Pr. 12, 538 [1863]). The following statement may be demonstrated by the use of the dynamical theory of heat. When the total volume of salt and solution is diminished (or increased) by the taking up of salt into the solution, then the solubility increases (or diminishes) with increased pressure. The researches of Braun (W. 30, 272 [1887]) have confirmed the

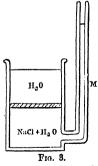

theoretical conclusions.

Dilute solutions. Osmotic pressure.-If a quantity of the pure solvent is floated on a solution, a movement of the dissolved substance takes place and the substance strives to distribute itself throughout the whole of the solvent. This occurrence is completely analogous with another; if a cylinder is filled with CO, and the mouth is covered with a membrane, another cylinder is filled with H and placed mouthdownwards on the first, and the membrane is withdrawn, the two gases begin to diffuse into each other (notwithstanding the action of gravi-'tation). The H is driven downwards by its partial pressure, and the CO, is driven upwards. The velocity of diffusion is proportional to this propelling force, otherwise it is dependent only on the freedom of motion of the molecules among each other. The inverse value of this freedom of motion is called molecular friction. The following statement expresses the results of experiment: the velocity of diffusion is proportional to the difference between the partial pressure of one of the two gases in the upper and lower parts, and is inversely proportional to the friction of the molecules. Solutions behave in a similar way. The substance in solution in the under layer strives to distribute itself into the upper layer; this striving corresponds to the pressure of a gas, and, as will be shown immediately, it is equal to the so-called osmotic pressure. solvent is driven downwards by the same force. In this case also the velocity of diffusion is proportional to the osmotic pressure, and is inversely proportional to the friction of the molecules of the dissolved substance against the solvent. The only difference between this case and that of gases is that molecular friction is very much larger in liquids, a fact that is explained by the great number of molecules against which a molecule of the dissolved substance collides during its movements.

The amount of molecular friction is known in certain cases, viz. for electrolytes. Let a cubical trough (sides 1 cm.) be filled with the solution of an electrolyte (e.g. NaCl), and let an electric current be passed through the trough by the help of two electrodes A and B. The positive electricity is carried by the metallic parts (Na) of the electrolyte in the direction of the current (towards B); the negative electricity travels with the negative radicle (Cl) of the electrolyte towards A. the Na and Cl atoms-or ions, as they are called in this case-are impelled by unit electrical force, the Na ions will move with a velocity vi and the Cl ions with the velocity v2 velocities can be determined, partly indirectly from the conductivity and the migration num-bers of Hittorff, partly directly by chemical analysis. Putting the corresponding frictions as r_1 and r_2 , then $v_1 = \frac{1}{r_1}$ and $v_2 = \frac{1}{r_2}$. The frictions of a large number of ions have been determined in this way. If we now have a layer of pure water floated on a solution of NaCl, in a vessel, then the velocity of diffusion, D, is equal to the quotient of osmotic pressure, O, and the frictions $r_1 + r_2$ of the salt. We have, therefore, $D = \frac{O}{r_1 + r_2}$. Nernst (Z. P. C. 2, 613 [1888]) has completely established the accuracy of this

formula.

Osmotic pressure can be measured directly. Let us suppose that in the foregoing example we had a division separating the solution of NaCl from the water, and that the division allowed water, but not NaClAq, to pass through it (a so-called semipermeable membrane); v. fig. 3. Such a membrane is obtained by impreg-

nating a plate of porous burnt clay with ppd Cu.Fe(CN). The water will then be driver downwards, and will be compressed in the lower part of the apparatus; the pressure in this division will increase; this may be confirmed by using a manometer (M, fig. 3). Equilibrium is attained after a time, and the manometer then indicates a certain pressure, which is called the

senctic pressure of the solution. When no more water is driven downwards, then, in the case in point, the partial pressures of the water in the apper and lower parts of the apparatus are equal. The excess of pressure in the lower part that is, the osmotic pressure -is then equal to the partial pressure of the NaCl molecules. Measurements of this kind have been made by Pfeffer, Tammann, and Adie (Osmotische Untersuchungen, Leipzig, 1877; W. 34, 229 [1888]; C. J. 59, 344 [1891]).

Semipermeable membranes are found in the lining of living cells which incloses the con-tents of the cell. De Vries made observations with cells of Tradescantia discolor and Begonia manicata; Donders and Hamburger used bloodcells. If a cell is immersed in water the cell swells, because of the entrance of water; if a soluble substance is added to the water, in constantly increasing quantity, the water will at last be driven equally inwards and outwards; if this limit is overpassed, the water passes out of the cell and the protoplasmic contents of the cell shrink together. The whole process may be followed by the help of the microscope. The limit reached immediately before shrinkage begins is characterised by the attainment of equality between the osmotic pressure of the cell-contents and that of the surrounding solution. By bringing similar cells into solutions of different substances it is possible, in this way, to determine the concentration that must be attained by two solutions in order that they may possess equal osmotic pressures. Using the results of Pfeffer and de Vries, van't Hoff made an examination of the magnitude of osmotic pressures. He found that the osmotic pressures exerted in their solutions by non-conductors of electricity—such as cane sugar, urea, glycerin, &c .- were exactly the same as the pressures which these substances would exert, in accordance with Avogadro's law, were they present as gases in the same volume as the volume occupied by the solutions. The osmotic pressure is therefore proportional to the concentration and the absolute temperature (law of Boyle and Gay-Lussac); this was confirmed by Pfeffer's investigations (van't Hoff, Handingar der Stockh. Ak. 21 [1886]; Ar. N. **20** [1885]; Z. P. C. 1, 481 [1887]).

An explanation of gaseous pressure is found in representing it as the result of the bombardment of the walls of the vessel by the gaseous molecules. Similarly, osmotic pressure is thought of as resulting from the knocking of the molecules of the dissolved substance against the walls of the containing vessel. The gaseous laws hold good in all respects for osmotic The gaseous

Vapour-pressures of solutions. Let there be a solution, say of cane sugar, in a trough, separated by a vertical semipermeable membrane from pure water, and let the membrane extend above the solution; the air above the liquid behaves exactly like the semipermeable membrane, inasmuch as it allows the water to pass through (as water-vapour), but it does not allow the cane sugar to pass through (because of the non-volatility of the sugar). The water has, therefore, a tendency to pass across through the air as well as through the semipermeable membrane from the water in the solution. This circumstance may be expressed by saying that the pressure of the water-vapour is greater over the water than over the solution. In like manner it follows that solutions which have equal osmotic pressures have also equal vapour-pressures. By making use of the second law of thermodynamics it can be shown (van't Hoff, l.c.) that a solution containing n molecules of dissolved substance to N molecules of solvent has a vapourpressure, P, which is given by the formula

$$P = \left(1 - \frac{n}{N}\right)p,$$

where p = the vapour-pressure of the pure sol-(The molecular weight of the solvent must be taken as that of the substance in the gaseous state at the same temperature.) This formula was originally experimentally established by Raoult; it agrees well with experience (C. R. 103, 1125 [1886]).

Boiling-points of solutions. According as the vapour-pressure of a solution is less than that of the solvent (assuming that the dissolved substance possesses no marked vapour-pressure), so the solution begins to boil, under a definite external pressure, at a higher te aperature than the pure solvent. The following formula may be deduced from the dynamical theory of heat: $E = \frac{0\cdot 2}{L} \cdot n,$

$$\mathbf{E} = \frac{0.2 \, \tau^2}{\Gamma_1} \cdot n,$$

where E is the increase in the boiling-point of the solvent brought about by dissolving n molecules of the substance in 100 grms. thereof, risthe absolute boiling temperature, and L is the latent heat of vapourisation of 1 grm. of the solvent. Beckmann has contrived an apparatus for determining E, and therefore for finding n-that is, for determining the molecular weight of the dissolved substance when the quantity thereof in 100 grms. of solvent is known. He has shown that the formula gives results which agree closely with experience (Z. P. C. 5, 76 [1890]).

Freezing points of solutions. When a solution is caused to freeze, in most cases only the pure solvent separates as a solid. The solid substance is in equilibrium with the solution at the freezing-point; hence, the vapour-pressures of the solvent over the solid and over the solution must be equal, as otherwise distillation would take place from the one to the other, and equilibrium would not be attained. For the sake of simplicity let us take water as the solvent. Ice and water have, therefore, the same vapour pressure at the freezing-point of the latter (0°); but an aqueous solution has a smaller vapour pressure at 0°; hence at 0° ice cannot have the same vapour pressure as an aqueous solution, but this equality occurs only at a lower temperature. In other words, the freezing-point of a solution is lower than that of the solvent. Van't Hoff (l.c.) has deduced the following expression from the dynamical theory of heat, $E = \frac{02 \tau^2}{W}$. n, where E is the difference

between the freezing-points of the pure solvent and a solution therein, which solution contains n gram-molecules of the dissolved substance in 100 grms. of the solvent, 7 is the absolute temperature, and W is the latent heat of fusion of 1 grm. of the solvent. This formula is of much importance, for the molecular weights of very many substances have been determined by its help. It is immaterial in this case whether the dissolved substance exerts a considerable vapour-pressure or not, for only the pure solvent freezes out. The following table gives some values calculated by the formula placed side by side with the values obtained by experiment, for the case where n = 1:

	E observed	E calculate
Water	18.9	18.9
Acetic acid .	38.6	38.8
Formic acid	27.7	28.4
Benzene .	50.0	53.0
Nitrobenzene	70.7	69.5

Electrolytic dissociation. When determinations of molecular weights are made, by the foregoing methods, based on osmotic pressures (de Vries), freezing-points (van't Hoff, Raoult), depressions of vapour-pressures (Raoult), or increments of boiling-points (Beckmann), the values obtained for all those substances whose solutions conduct electricity are much smaller than would be expected. For instance, the results obtained by working with a half-normal solution of NaCl lead to the value 31-6 for the molecular weight of the salt, a number which is 1.85 times smaller than the calculated value, 58.5 (NaCl). From this and many other considerations Arrhenius drew the conclusion that the molecules of electrolytes are largely dissociated in aqueous solutions; about 85 p.c. of the NaCl, for instance, in an aqueous solution of this salt is regarded as dissociated into Na and Cl. This conclusion is completely analogous with those which are drawn regarding the dissociation of the molecules of ammonium salts and other substances, in the gaseous state, from observations of the abnormal vapour densities of these substances. The development of the theory of electrolytic dissociation, based on these considerations, and confirmed in the fullest way by experience, has lent much support to the theory of solutions which has already been sketched. This part of the subject is treated by Ostwald in the article ELECTRICAL METHODS, to which reference should be made (this vol., pp. 187-221).

Some of the deductions regarding diffusion, solubility, and affinity must, however, be mentioned here.

Diffusion of mixtures. When a solution of HCl is placed in contact with pure water, the HCl gradually diffuses into the water. Inasmuch as most (almost all) of the HCl molecules are dissociated, one would expect the diffusion to result in a separation of the H and Cl from each other, just as the alums and the double salts of the sulphates of the alkalis and the magnesium metals, which are partially decomposed in aqueous solution, can be separated into their constituent salts in this way (Graham, T. 1850. 1, 805; Marignac, A. Ch. [5] 2, 546 [1874]). But this separation does not occur. The H moves into the water more quickly than the Cl, and, because of the positive electrical charge of the H ions, the water becomes positively and the solution negatively charged. If this charging is not carried off by metallically connected un-polarisable electrodes placed in the solution and in the water (v. this vol. p. 212), it prevents the separate diffusion of the H and the Cl. But there is another way whereby the restrain- | p. 81).

ing force of the electrical charge on the diffusion of the H may be diminished—namely, by addition of chlorides. For instance, the velocity of diffusion of HCl (properly speaking, of H) is increased in the ratio of 1:224 by adding 25 times the quantity of NH, Cl (Arrhenius, Z. P. C. 10, 51 [1892]). Similar, although not so strongly marked, characteristic phenomena, which find an explanation in the dissociation theory, have been observed by Graham and Marignae.

Decrease of solubility by addition of foreign salts. Nernst (Z. P. C. 4, 372 [1889]) was the first to draw attention to the conclusion from the theory that a slightly soluble salt, e.g. silver acetate, must be more soluble in pure water than in a solution that contains other silver ions (e.g. AgNO₂) or acetate ions (e.g. NaC,H₂O₂). Similar relations are shown by gases which partially decompose (e.g. NH,SH); these exhibit smaller vapour-pressures when one of the two components (NH, or H,S) is added. This lowering of solubility can be calculated from the laws of mass-action, with results which agree well with experience (Noyes, Z. P. C. 9, 603 [1892]).

Division of a dissolved substance between two solvents. Berthelot and Jungfleisch examined the distribution of succinic acid between ether and water, and found that the concentrations of the acid in the aqueous and in the ethereal solution were in a constant proportion, which appeared to be independent of the absolute concentration. Many other substances were found to behave in the same way (A. Ch. [4] 26, 396, 408 [1872]). This result corresponds completely with Henry's law for gases. It is readily deduced from the theory; but in doing this it is assumed that the dissolved substance has the same molecular weight in both solutions. If this is not the case—as, for example, in the distribution of benzoic acid between benzene and water-altogether different laws express the phenomena (these laws, also, are in keeping with experimental results; Nernst, Z. P. C. 8, 110 [1891]).

Reaction velocities. There are many so-

Reaction velocities. There are many socalled catalytic processes that are brought about by the H ions of acids—for instance, the inversion of cane-sugar, saponification of esters, &c. According to the theory, the velocity with which these reactions take place must depend only on the number of H ions that are present, and not on the nature of the reacting acid. This conclusion is confirmed by experience (Arrhenius, Z. P. C. 4, 226 [1889]; cf. Affinity, vol. i., especially pp. 77-81).

Division of a base between two acids present in equivalent quantities. Thomsen made investigations regarding the quantity of a base (NaOH) that reacts to form salts with two acids (e.g. HCl and HF) added in equivalent quantities. He found that, in the case quoted, 95 p.c. NaCl and only 5 p.c. NaF were formed in dilute aqueous solution. It may be deduced from the theory that the quantities of NaOH combining with the two acids (HCl and HF) are in the same ratio as the extents of dissociation of the acids at the same dilution. The observations of Thomsen and of Ostwald agree extremely well with this deduction from the theory (Arrhenius, Z. P. O. 5, 14 [1890]; cf. APPINITY, vol. 1, n. 81).

Influence of temperature on rate of solution. If a finely and equally powdered substance is shaken with a solvent at two different temperatures, for a very short time, the rapidity of solution is found to increase rapidly with the temperature. For instance, the rates of solubility in water of cream of tartar and benzoic acid increase between 0° and 17° in the ratios 1:38 and 1:31.

So-called solid solutions. Palladium is able to take up much H, but the mixture retains the solid form. There is, therefore, here no proper solution; nevertheless, van't Hoft has shown that the laws which hold good for solutions are valid for this phenomenon also (Z. P. C. 5, 322 [1890]). There is formed at first an alloy, Pd.H, which possesses a definite dissociation pressure. If the pressure of the H is increased more H is absorbed, and the quantity absorbed is in direct proportion to the excess of pressure of the H. Henry's law, therefore, holds good. On this ground van't Hoff called mixtures similar to this 'solid solutions.' Solid solutions of thiophene and benzene have been examined by van Bijlert (Z. P. C. 8, 343 [1891]).

Heats of solution. A considerable quantity of heat is generally produced during the solution of a substance in a solvent. The heat of solution of a substance is defined to be the quantity of heat that appears during the solution of a gram-molecule of the body in much water. The following table gives the heats of solution of some of the commoner substances. Most of the numbers are taken from Thomsen

(Th. 3, 195).

Volume changes accompanying solution. In most cases the solution of a substance in water is accompanied by a considerable amount of contraction. For instance, a mixture of 100 c.c. alcohol with 100 c.c. water measures only 192-8 c.c. at 18°. The contraction may be so great that the volume of the solution is less than the volume of the water used as solvent: for instance, when Na₂CO₃, NaOH, or LiOH is dissolved in much water. The following table shows the volume change, in c.c., that takes place when one gram-equivalent of some of the most important compounds is dissolved in much water—e.g. in 10 litres:—

		п	Na.	K	NH.
\mathbf{oH}		18	- 5.8	8.6	
Cl.		18.3	16.6	26.9	87.4
NO.	•	29.0	28.0	38.5	48.2
³ So⁴		16.2	6.4	15.7	24.2

A mixture of 40 grms. NaOH with 10 litres water occupies, therefore, a volume of 9994.2 c.c.

When the solvent is other than water an increase of volume sometimes takes place; for instance, a mixture of 100 c.c. alcohol with 100 c.c. CS₂ occupies about 202 c.c.

Specific heats of solutions. The water value of a solution of a salt in water is not equal to, but is generally less than, the sum of the water values of the water and the salt. In a few cases this decrease is so great that the water value of the solution becomes less than that of the water used as solvent. The following data show the water values of one gram-equivalent of the chief salts in extremely dilute solutions (according to the determinations of Thomsen):—

The water value of a solution of 40 grms. NaOH in 10 litres water, for instance, is not only not greater than that of the water alone (10,000), but is distinctly smaller (9,973).

Deviations shown by concentrated solutions. The laws that have been stated for the osmotic pressure, the lowering of freezing-point, the raising of boiling-point, and the lowering of vapour-pressure, brought about by substances in solution, are valid, strictly speaking, only for very dilute solutions. Deviations from these laws occur when the solutions are more concentrated. Sometimes the observed values are smaller than those theoretically deduced. In such cases it is supposed that molecular aggregates are formed. This occurs, for instance, gates are formed. with solutions in benzene of oxims, alcohols, phenols, and fatty acids, and also with fairly concentrated aqueous solutions of the sulphates of Mg, Cu, Zn, and Cd, and CdI2 (Beckmann, Z. P. C. 2, 737 [1888]; Arrhenius, Z. P. C. 2, 496 [1888]). On the other hand, most concentrated aqueous solutions give values greater than the calculated values; this is made especially evident by Tammann's investigations into the vapour-pressures of salt solutions at 100° (Mem. de l'Acad. de St. Pétersbourg [7] 1, 85 [No. 9, 1887]). An explanation of this behaviour has been sought for in the attraction between the

solvent and the dissolved substance (Arrhenius, Z. P. C. 10, 40 [1892]). S. A.

SOLUTIONS II. The view that hydrates exist in aqueous solutions, and analogous compounds in non-aqueous solutions, is one which has long been held by many chemists; it is only in the last few years, however, that the hydrate or association theory has assumed a precise form, and that definite experimental evidence in support of it has been accumulated. In giving some account of the present position of this theory it will be convenient to collect the evidence on which it depends under the headings 'general' and 'special,' and to discuss separately the bearing which recent work on dilute solutions has upon it. Aqueous solutions have naturally been more studied than solutions in other solvents. but these other solutions have been investigated sufficiently to show that they are similar to aqueous solutions in every respect, except as regards electric conductivity. Although, therefore, to simplify matters in the present article, in most instances aqueous solutions alone are mentioned. it must not be understood that the arguments do not apply equally to other cases.

General. The changes accompanying dissolution seem to be in every respect similar to the recognised accompaniments of chemical combination: evolution of heat, a more or less profound alteration in the nature of the reagents, and an irregular variation in the properties of the resulting solution with regular variations in the proportions of dissolved substance and solvent. For reasons which will be mentioned below, these irregularities may often not be very pronounced, but it may safely be stated that every attempt which has been made to express the properties of any series of solutions by a simple expression agreeing, within the limits of experimental error, with the observed values throughout a wide range of concentration has been unsuccessful.

The affinity which a large number of substances possess for water, as evidenced by the many solid compounds which they form with it, and by the heat evolved in their formation, renders it prima facie extremely improbable that these substances should exist in presence of excess of water without combining with it. It is, moreover, those very substances which exhibit the greatest tendency to form solid hydrates which are generally most soluble. more careful study of the thermal phenomena of solutions places this argument beyond the range of mere speculation. From the known heat of fusion of water and of a few anhydrous salts we can obtain a very close estimate of what the heat of fusion of any hydrated salt would be, if no change beyond the mere passage from the solid to the liquid condition occurred; with hexahydrated calcium chloride, for instance, the heat of fusion under such circumstances would be 11,000 to 12,000 cal., and on the most exaggerated estimate could not exceed 14,000 cal., whereas if decomposition as well as mere liquefaction occurred the heat absorbed would be at least 25,000 cal., since the heat of fusion of the 6H2O alone is 9,500 cal., and the heat of combination of CaCl₂ with 6H₂O (both solid) is 14,500 cal. The observed heat of fusion, however, is only 11,417 sal, a value which disproves that any consider-

white change beyond mere liquefaction has occurred during the fusion—i.e. the combination which existed in the solid must exist also in the liquid. The data in the case of sulphuric acid afford more striking evidence of a similar character. The heat of combination of solid water with the solid acid to form the solid monohydrate is 6,550 cal., and if, when the reagents are mixed in the liquid condition, they do not combine chemically, far less than this amount of heat would be evolved; whereas the heat actually evolved is found to be almost identical with the above, namely 6,667 cal.

The separation of a crystalline hydrate from a solution is an argument to which due weight has hardly yet been attributed in favour of the existence of that hydrate in the solution, although not necessarily in large quantity. If there are no molecules of the hydrate existing as such in the liquid, these must have been deposited in the solid form at the moment of their formation, whereas we know that whenever deposition occurs simultaneously with formation, as in the precipitation of an insoluble salt, the substance is deposited in the amorphous and not in the crystalline condition.

If, as would appear to be the case, it is necessary to admit the existence of hydrates in concentrated solutions, it is necessary to admit their existence in dilute solutions also. The mass action of an excess of one or other of the constituents of any composite fluid is well known, and is universally accepted: it must operate with hydrates as much as with other substances, and must do one of three things: either (1) it must increase the stability or amount of the particular hydrate present, or (2) it must combine with it to form a higher hydrate (if it is the water of which excess is added), or (3) it may decompose the hydrate by reacting with the non-aqueous constituent of it to form new compounds, as when free alkali and acid are produced (a decomposition, however, which can be proved in many cases to occur to but a negligible extent), but in no case could excess of water decompose the hydrate taken so as to liberate the dissolved substance in the anhydrous condition. The thermal phenomena of solution afford important evidence in this case also; to interpret them properly, however, it must be remembered that the dissolution of a substance in excess of solvent entails the separation of the particles of that substance from each other to the same extent as if it were vapourised, and that to effect this separation the same amount of heat must be absorbed in either case. The heat evolved due to the reaction of a liquid with excess of solvent is, therefore, the observed heat of dissolution minus the heat absorbed in vapourisation, and, in the case of a solid, the heat of fusion as well as that of vapourisation will have to be subtracted. Making allowance for these so-called physical changes, we find that the formation of every concentrated solution—that is, a solution which contains hydrates -is accompanied by the evolution of heat, and inasmuch as, with the same allowance, dilution is always accompanied by a further evolution of heat, the action of the diluent cannot be regarded as a reversal of the initial reaction, but rather as an extension and completion of it, the hydrates present in the concentrated solutions soing increased in amount or in complexity thereby. When matters are simplified by dissolving a gas, instead of a liquid or solid, and adjusting the pressure of the gas or the quantity of solvent so that the former occupies the same volume after as before dissolution, we still find that a very considerable evolution of heat occurs; with the haloid acids this is as much as 17,000 cal., and though this may be glossed over by some of the advocates of the physical theory by stating that the decomposition of the acids into their ions, which they consider occurs, evolves a very large amount of heat, no such explanation can be offered in cases where no such decomposition is imagined, and it has been proved that the dissolution of gaseous non-electrolytes both in water and in other solvents is accompanied by the evolution of as much as 5,000 to 14,000 cal. In the face of such a considerable loss of potential energy, it is impossible to maintain that the substances losing it remain unchanged, and that the dissolved substance can, in any true sense, be still gaseous and uncombined with the solvent. It is important to note that van der Waals, through a different line of reasoning, has arrived at the same conclusion as to the necessity of recognising some action evolving heat between the substance and solvent, even when the former is in the so-called dissociated condition.

Amongst the general considerations favouring the view that dissolution consists in the formation of liquid compounds, not the least important is that this gives us some intelligible reason for dissolution occurring at all, whereas if the solvent is regarded as being inert and only playing the part of so much empty space (as some of the advocates of the physical theory have maintained), we have no explanation of why dissolutions occur; the presentation of empty space to a stable solid does not make the latter fill the empty space, and even attributing dissolution to the possession of a certain 'solution pressure' by the dissolving substance would appear to amount to no more than stating that a substance dissolves because it does do so.

Special. Berthelot determined the heats of dissolution of various series of solutions of different concentrations, and concluded that his results when plotted out showed the presence of changes of curvature or inflections at certain points, indicative of the existence of hydrates in the solutions. In many cases he adduced various special considerations in support of the existence of the hydrates thus indicated, but his determinations were not sufficiently numerous or accurate, nor were his methods of examining them sufficiently precise, to lead to more than vague conclusions Thomsen's investigations on the same subject were equally unsatisfactory; he sought to disprove the existence of any such changes of curvature by finding empirical equations to represent each series of results, but in the four cases which he thus investigated the equations deduced express but a small portion of the whole series, leaving in the remainder errors ten and a hundred times greater than the experimental error. Mendeleeff next took up the question from a different point of view. Theoretical considerations led him to conclude that solutions consisted of different hydrates according to the

amount of water present, and that, if not more than two hydrates were ever present together in the same solution, there would be definite changes of curvature in the figures representing the properties of the solutions at the concentrations corresponding to these hydrates; that is, that the rate of change in the property with change of concentration would be different when the solutions consisted of the hydrates A and B from what it would be when they consisted of B and C, so that there would be a change at a concentration corresponding to the composition of B, and further, he concluded that these rates of change (first differential co-efficients) in the case of the densities would be rectilinear functions of the percentage composition between the points A and B. B and C, &c. (It should be noticed in passing that the idea which lies at the root of Mendeléeff s conception-and, to a certain extent, of Berthelot's also-is that the water in any solution is nearly entirely combined with the dissolved substance, and not merely that the solution consists of a simple hydrate mixed with excess of free water.) That the concentration-rate of change of the densities is representable within experimental error by a series of straight lines is probably true in many cases, but in the two cases on which Mendeleeff chiefly relied for proof these first differences are conspicuously curvilinear throughout. The reason of this, doubtless, is that solutions of a given concentration generally contain more than the two hydrates which he postulated. Roozeboom's work on ferric chloride, and Pickering's on sodium hydroxide, render it probable that five or six hydrates may co-exist in the same solution; at any rate, as many as four have actually been obtained from certain solutions. Pickering next attacked the subject from a purely experimental point of view. The distinctive feature of his work is the search for changes of curvature (breaks) by the application of a flexible lath to his plotted results. A lath bent by the application of two couples near its extremities forms, for all practical purposes, a curve of a very simple nature; and it has been proved that the use of such a lath is tantamount to, and leads to precisely the same conclusions as, the application of ordinary parabolas with three or four constants deduced mathematically from the experimental values; and in several respects, besides expeditiousness of application, this method is superior to the mathematical method. The mere fact that a certain figure may be represented accurately by a series of parabolas is by itself no proof that it really consists of these independent curves, any more than the existence of breaks can be disproved by finding an artificial equation which will bridge them over; the correctness of any particular form of representation can be measured only by the results to which it leads, and in this respect the discontinuous expressions would appear to be highly satisfactory. The positions of the breaks are not dependent on the taste of the draughtsman: the figures examined seem to split up naturally into certain sections only, and when drawn in these sections it was found, in some dozens of series of experiments, that the apparent error of the points agreed within 5 or 10 per cent. with the known experimental error (though in a great number of the cases the true

magnitude of the latter was not as after the drawings were made), whereas drawings of a similar character, but placing the breaks at other points, or drawings obliterating the breaks altogether, represented the error of the points to be far larger, often 10 or 100 times larger, than the known experimental error. It must be remarked that, once the magnitude of the experimental error is known with certainty, no drawing can be accepted unless it agrees closely with it. and Pickering has devised a method by which the experimental error can be accurately determined independently of any considerations other than the examination of the final results themselves; he has also devised a means of obtaining a numerical estimate of the acceptability of any drawing, by combining together the various factors which are usually taken as affording a criterion of acceptability. Again, when sections of increasing lengths are taken, and these are represented by single parabolas, or bent-lath curves, there is little or no increase in the apparent error of the points till the sections extend beyond a point where one of the supposed breaks exists, but as soon as they do so there is a large and sudden increase, indicating that some real change at the point in question exists. Moreover, it has been shown that in a case where two parabolas will represent a series of results perfectly, a single parabola will not do so, even if it contain as many constants as the two parabolas together contain. The strongest argument, however, in favour of the reality of these breaks is that the various properties of any series of solutions, although they form figures differing from each other widely in general form, are yet all thoroughly concordant as to the positions at which the breaks occur. The properties of sulphuric acid which were investigated were the densities at four temperatures and the contraction on mixing deduced from them, the heat of dissolution, the thermal expansion, the electric conductivity (Kohlrausch's values), and the thermal capacity; subsequently also the freezing-points and van der Willigen's values for the refractive indices were investigated. Perkin also found indications of two of the breaks in his determinations of the magnetic rotations, and still more recently Féry has recognised some other of the breaks in his own measurements of refractive indices. Three different properties were also examined by Pickering in the case of calcium chloride and nitrate, and were found to show a similar concordance.

That the breaks are really due to, and indicate the presence of, compounds in solution is shown by the fact that, not only in the cases above mentioned, but also in many others where other solvents besides water were used, they always occur at points which correspond within small limits with definite molecular proportions -wherever, that is to say, the proportion of substance to solvent is sufficiently simple to permit of any conclusions at all being drawn in the matter. Further evidence on this point was also afforded from a study of the freezing-points of fourteen of the alkyl amines, where, with one exception, hydrates of the very compositions indicated by breaks in the case of some of the amines were isolated in the crystalline condition in the case of the others. Finally, as a more striking, though perhaps not more cogent, argument, we

no less than six new hydrates, the existence of which had been foreshadowed in the properties (chiefly densities) of the solutions—namely, H₂SO₄4H₂O, HBr.3H₂O, HBr.4H₂O, HCl.3H₂O, HNO₄.H₂O, and HNO₂.3H₂O—the last three being especially conspicuous examples, for the only marked breaks which the densities showed coincided with the only hydrates which were subsequently isolated.

Two important features of the conclusions drawn from the above-mentioned work on sulphuric acid should be mentioned; firstly, the large number (18-20) of hydrates of which indications were obtained; secondly, the complex nature of hydrates in very dilute solutions. Any improbability which might be considered to attach to the former conclusion (though, in reality, no data exist on which to found any estimate of the probabilities in such a case) is removed by the fact that a still larger number of hydrates (when equal ranges of concentration are compared) have been isolated in the crystalline condition from solutions of sodium hydroxide. The complexity of the hydrates indicated extends up to compounds with hundreds and even thousands of molecules of the solvent, but, with the explanation to be mentioned below as to their possible constitution, these hydrates can scarcely be branded as improbable; at any rate. the breaks which indicate their existence appear to be precisely similar in nature to those which indicate the presence of the simpler hydrates. Pickering has investigated the freezing-points of many dilute solutions besides those of sulphuric acid, and has found that nearly all of them show indications of similar changes, and those recognised in the cases of sodium chloride and sulphuric acid have received further confirmation from a series of results made by H. Jones; a confirmation of special importance, since Jones's determinations were made with the view of disproving the existence of breaks. Complex hydrates, though of a comparatively small degree of complexity, would appear to exist in regions other than those of very dilute solutions; two such were indicated in the neighbourhood of the monohydrate of sulphuric acid, and a similar one, perhaps another also, has been isolated in the case of soda. These are probably compounds of two different hydrates.

It is important to note that the changes of curvature here described need not necessarily be absolutely abrupt. On the strength of experimental evidence only, where experimental error necessarily exists, it is obviously impossible to prove or disprove the abruptness of any change, and no satisfactory mathematical theory has yet been formulated to lead to any views on the subject. It is sufficient for the purpose that comparatively abrupt changes exist. Nor should it be expected that these changes would necessarily be of a very marked character, for a large proportion of the factors determining the properties of solutions must be of a purely physical or even mechanical character; the densities of sulphuric acid solutions, for instance, must rise more or less gradually from 1 to 1.85, and it is only in

It should be noted that Jones himself asserts that his results entirely disprove Pickering's 'breaks' (c. B. 26, 547, 1633).—M. M. P. M

the variations from the 'more to the 'less' that we can expect to find evidence of inter-

mediate compounds.

Application of the hydrate theory to explain the properties of dilute solutions. Diversity and irregularity are some of the most marked features of the properties of concentrated solutions, and though in dilute solutions these irregularities are much less conspicuous (as, indeed, we should expect them to be when the hydrates present become excessively complex and, consequently, excessively unstable), they are still recognisable, and it is only in the most extreme dilution, where the experimental error amounts to a large fraction of the total quantities measured, that the results can be expressed within the limits of this error as an apparently regular function of the concentration. It may safely be stated that any purely physical theory which confines itself to regions of extreme dilution, and which ignores some of the most marked features of dissolution. as well as the mass of direct evidence showing the existence of compounds in solution, cannot be accepted as a complete theory; nor, on the other hand, can the hydrate theory of solutions be accepted as satisfactory unless it can be shown to be consistent with the two main characteristics of weak solutions—the apparent quasi-gascous independence of the dissolved substance in dilute solutions, and the approximately accurate results which are obtained when calculations are based on the assumption that electrolytes in dilute solutions are dissociated into their ions. However important the service rendered to science by the gaseous and dissociation theories of solution, there are many fundamental objections which militate against their universal acceptation. They offer no satisfactory explanation of why substances dissolve at all, and still less why water alone, of all ordinary solvents, should resolve salts, &c. into their ions. These ions are represented to be atoms charged with enormous electric charges, but no explanation is given of the origin of these charges, or of the peculiarities which they are supposed to exhibit; two atoms oppositely electrified are represented as being less combined than when not charged at all; the charged atoms are represented as swimming about in the water without decomposing it, and without giving up their charges to their oppositely electri-fied companions, although they can part readily with them to an electrode; and to explain the thermal phenomena of solution, it has to be boldly assumed that the decomposition of molecules (elementary or composite) into charged atoms often evolves a considerable amount of heat, and consequently that the charging of an ordinary atom must be a process which evolves heat also. The only crucial experiment which has so far not been susceptible of an opposite interpretation seems to disprove any real dissociation of electrolytes. The lowering of the freezing-point of a solvent is accepted as affording a measure of the number of acting units (molecules or ions) in any substance added to it, and when, for instance, to some acetic acid a weak solution of sulphuric acid is added, the depression produced proves that the latter con-tains fewer acting units than the water and sulphuric acid do separately, instead of more, as

would be the case if the sulphuric acid molecules had to be split up into independent ions.

In a paper in the Berichte, Pickering has offered an explanation of the behaviour of dilute solutions based on the hydrate theory and on the views held by him as to residual affinity. The explanation may be rendered more intelligible by representing chemical attraction, as we represent electrical attraction, to be due to 'charges' on the surfaces of the attracting matter, but inalienable from the matter, owing to a repulsive force between the atoms similar to that which produces elasticity preventing the atoms ever coming close enough together to allow of the charges combining. The charges are represented as being always self-attracting. Each atom possesses one or more unit affinity. charge according as it is a monad or a polyad: with a free atom the charge would be uniformly distributed over its surface, whereas when two atoms are combined the greater part of the charges would be drawn to those sides of the atoms facing each other; but, as in the case of electric charges, a certain amount would still be left on the further sides capable of acting on, and being acted on by, other atoms or molecules in like condition, this residue, or unbound charge, forming what appears as residual affinity. As in the case of electrical charges, the nature of the matter composing different atoms will cause different degrees of mobility in the charges on their surfaces, and hence different pairs of atoms will be held together with different degrees of firmness, and different molecules will exhibit different amounts of residual affinity. When a molecule A B, possessing a certain amount of residual affinity, is surrounded by a number of other molecules CD possessing residual affinity also, the two residual charges will react on each other and increase the amount of the charges on the external portions of the molecules, leaving a smaller amount of charge on the portions of A and B which face each other; in the same way the charge on C will be partially withdrawn from the surface facing D, and will be able to retain a smaller amount of D's charge on the portion of D which is next to it, so that D will exhibit more residual affinity than formerly, and will be able to react in a similar manner on its neighbours, C' D'. Thus, by a process precisely analogous to electric induction, the number of molecules of C D which are acted on by, and are more or less combined with, A B may be very large, and far greater than the number which are capable of coming into its immediate vicinity. The existence of the very complex hydrates which have been recognised in dilute solutions is thus easily explicable. It is evident that a molecule when thus surrounded by, and combined with, a large number of solvent molecules will be attracted equally in every direction, and as the magnitude of the force exerted on it by each individual solvent molecule must be very small, it will be able to move easily in any direction, especially as any of the solvent molecules from which it parts during the process will have their places supplied at once by other similar molecules, of which, owing to continuous dissociation and recombination, there is an abundant supply in the liquid. Thus, into whatever new position the sentral morecure moves, the status quo ante is immediately reproduced, and, consequently, the molecule will move almost unfettered by the presence of the solvent, and will act almost as if it were in the gaseous state. We thus obtain at once an explanation of why the application of the ordinary gaseous laws to dilute solutions yields very nearly true results; we should, indeed, expect that they would not be absolutely true, for certain definite numbers of solvent molecules would be capable of a more symmetrical arrangement about the central molecule than others, and such arrangements (definite hydrates) would be more stable than others, and the tendency to form them might have an appreciable effect on the regularity of the results: small irregularities of this sort are exactly what we find in the case of those dilute solutions which have been fully examined.

It is obvious that as the quasi-gaseous freedom of the molecule is dependent on its being combined with the solvent, this freedom obtains only so long as the molecule remains within the solvent, and would not admit of the possibility of its leaving the liquid, or of exerting an external gaseous pressure; for the same reason it would be impossible for it to pass through any crevice so small as not to allow it to retain as many solvent molecules as it was combined with in the solution. This gives us an explanation of the action of semipermeable diaphragms and all the phenomena of osmotic pressure; it, moreover, removes a difficulty which must be experienced in accepting the explana-tion given by the supporters of the physical theory of the action of these diaphragms—why it is that the water molecules (which are admittedly combined in great part into complex aggregates) can so easily pass through interstices which are impervious to what are held to be the single free molecules and ions of the dissolved substance. Direct experiment would seem to decide conclusively in favour of the explanation of osmotic pressure given above, for, when a suitable solution in a porous pot is immersed in either of the substances which compose the solution, osmosis through the pot towards the solution occurs in both cases, showing that osmotic pressure is not due to the impermeability of the pot to either of the constituents of the solution, but to its impermeability to the solution as a whole.

In a case where the atoms of the dissolved molecule possessed a considerable amount of residual affinity, the action and reaction between them and the solvent molecules would, in every respect, be proportionally great, and, con-sequently, those portions of the whole charges which are utilised in uniting the component atoms of the dissolved substance would be reduced, and, in extreme cases, might be reduced to the lowest possible limits-that is, till the amount of affinity utilised in holding them together was equal to that utilised in attaching them to the solvent molecules, in which case there would be an equal distribution of the affinity charges over the atoms. The atoms composing a molecule in such a condition would have a great amount of freedom of motion within the molecule; being attracted equally in all directions, they would be at liberty to start to

move in any direction, and their movements might attain considerable amplitude under suitable conditions as to the rate at which the forces between them varied with the distance; for to explain the apparent independence of the atoms, and therefore the abnormal osmotic pressure of a salt molecule, 'it only requires.' according to Fitzgerald, 'the space within which [the atoms] are bombarding about to be small compared with the space rate of variation of the force between [them].' The atoms of the two molecules in such a condition would obviously change partners very readily during collision, and this gives us an explanation of why such an interchange does take place when two different salts, &c., are mixed. This ready exchange, moreover, would take place continuously, and in a definite direction, under the influence of any external force, such as a charged electrode, a Grothüss' chain being formed, and we should consequently expect to find that substances in this condition—i.e. those which give abnormally large osmotic pressures—were electrolytes; this is so: and since, moreover, the amount of electrolysis occurring in a given time under a given force would be proportional to the number of molecules in the condition postulated, it follows that this number-and, therefore, the osmotic pressure-could be calculated, at any rate approximately, from the conductivity. In short, whatever calculations hold good on the assumption that the atoms in the molecules are absolutely independent will also hold good if they are assumed to be in the peculiar condition of combination here described—a condition which is brought about by their great tendency to combine with the solvent, and not by a tendency to part company for no assignable reason. On the present view also it is possible to understand why it is that salts and acids are generally electrolytes, and why water is the solvent which makes them electrolytes, for both salts and water are composed of elements which have a strong attraction for elements of an opposite character, and in such a case the residual affinity of both the elements (basylous and chlorous) constituting the salt would be acted on by that of the two opposite elements constituting the water, and we would get an amount of mutual reaction which would be impossible in the case of other anhstances.

SONNENSCHEIN'S REAGENT. Prepared by adding phosphoric acid to a warm solution of ammonium molybdate in nitric acid, boiling the pp. with aqua regia to destroy NH₂, evaporating to dryness, and dissolving in 10 p.c. nitric soid (A. 104, 45). This reagent gives yellow

pps. with alkaloids.

SOPHORIN. S. . 009 in the cold; .5 at 100°. S. (alcohol) ·8 in the cold; 7 at 78°. Obtained from Chinese yellow berries, the undeveloped flower buds of Sophora japonica (Stein, J. pr. 58, 899; 85, 351; 88, 280; Spiess a. Sostmann, J. 1865, 587; Förster, B. 15, 216). Decomposed by boiling dilute H.SO, into isodulcite and

yellow sophoretin, which resembles quercetin.
SOPHORINE. An alkaloid obtained from the pods of Sophora speciosa (Wood, Ph. [3] 8, 1047). Liquid, forming a crystalline hydro-chloride, which gives a deep-red colour with FeCl. Poisonous. A poisonous alkaloid may also be obtained from the seeds of Sophora tomentosa (Greshoff, B. 23, 3539).

SORBIC ACID C.H.O. i.e. CH₃.CH:CH:CH:CH.CO,H. Mol. w. 112. [134.5°]. (228°). H.O. 730,000 (Ossipoff, J. R. 20, 650). Heat of neutralisation: Gal a. Werner, Bl. [2] 46, 802). Occurs in the juice of unripe mountain ash berries (Hofmann, C. J. 12, 43; A. 110, 129). The juice is partially neutralised with milk of lime, decanted from acid calcium malate, and distilled after addition of H2SO4. Needles (from dilute alcohol), v. sol. alcohol and ether, in. sol. hot water, volatile with steam. Partially decomposed on distillation (Barringer a. Fittig, A. 161, 307). Has no odour. Br in CS2 forms tetra-bromo-hexoic acid [179°] and di-bromo-hexenoic acid [90°-95° Fuming HBr forms di-bromo-hexoic acid [68°] (Stahl, B. 9, 120). Very dilute alkaline KMnO. at 4° gives aldehyde, racemic acid, oxalic acid, and CO2 (Doebner, B. 23, 2376). Sodium-amalgam forms hydrosorbic acid.

Salts. BaA'2. - CaA'2: silvery scales.

AgA': white crystalline pp.

Ethyl ether EtA'. (195.5°). Liquid. Chloride C.H,OCl. Converted by NH, and aniline into crystalline C₆H₇O.NH₂ and C.H.O.NHPh respectively.

Hydrosorbic acid v. HEXENOIC ACID. Isosorbic acid v. HEXINGIC ACID. Reference .- Oxy-sorbic acid.

SORBINOSE G_1, Q_0 i.e. $CH_2(OH)$. (CH.OH), CO.CH₂(OH). (CH.OH), CO.CH₂(OH). An unfermentable sugar obtained from the fermented juice of mountain-ash berries (Pelouze, A. Ch. [3] 35, 292; Byschl, J. 1854, 664; Delffs, C. N. 24, 75). The juice is left to stand for a year, and then filtered and evaporated. Trimetric crystals, as sweet as cane sugar. Lavorotatory. V. e. sol. water, sl. sol. hot alcohol. Forms with NaCl a compound crystallising in cubes. Its aqueous solution dissolves CaO, PbO, and Cu(Oh)₂. Not attacked by Br. Yields tri-oxy-glutaric acid on oxidation by HNO₃ (Kiliani a. Scheibler, B. 21, 8276), but no mucic or saccharic acid (Tollens, A. 249, 222). HIAq and P yield hexyl iodide. Reduced by sodium amalgam to sorbite (Vincent a. Delachanal, C. R. 111, 52). Not turned brown by hot alkalis. Reduces Fehling's solu-Bromine water yields glycollic acid (Hlasiwetz a. Habermann, A. 155, 120). On heating sorbinose (1 pt.) on the water-bath with a solution of phenyl-hydrazine hydrochloride (2 pts.) and NaOAc (3 pts.) in water (10 pts.) it phous.—B"H_PtCl, 2aq. Decomposed by boiling Vot. IV.

yields the osazone $C_{10}H_{22}N_4O_4$ [164°], which crystallises in yellow needles, sl. sol. hot water, v. sol. alcohol, v. sl. sol. ether (Fischer, B. 17. 582; 20, 827).

SORBITANNIC ACID. Obtained from the berries of Sorbus aucuparia (Vincent a. Delachanal, Bl. [2] 47, 492). Gives a yellow colour with alkalis; reduces silver salts in the cold; is not ppd. by alum or gelatin. Potash-fusion forms protocatechuic acid and phloroglucin.

SORBITE $C_6H_{14}O_6$. Mol. w. 182. [1117]. $[\alpha]_D = -1.73^\circ$. Occurs in mountain-ash berries (Boussingault, A. Ch. [4] 26, 376); in plums, cherries, and the fruits of nearly all the Rosacea (Vincent a. Delachanal, C. R. 108, 147; 109, 678; 111, 52). Formed on reduction of sorbin and of l-gulose (Fischer a. Stahel, B. 24, 2144). Formed also, as well as mannite, by reducing glucose (dextrose) with sodium-amalgam in the cold (E. Fischer, B. 23, 3684; Meunier, C. R. 111, 49). Pearly crystals (containing and). Melts at 75° when hydrated. V. sol. water and hot alcohol. Neither ferments with yeast nor reduces Fehling's solution. Levorotatory, becomes dextrorotatory on addition of sodium borate (Vincent a. Delachanal, C. R. 108, 354). HIAq yields (β)-hexyl iodide (Hitzemann a. Tollens, B. 22, 1048). Boiling with Ac₂O and some ZnCl₂ forms a hexa-acetyl derivative. Benzoic aldehyde and a little hydrogen chloride give C₆H₁₃O₅(C,H₅O), crystallising in rectangular prisms [c. 175°]; if more acid is present the insoluble compound C,H,2O,(C,H,O), [162°] is formed (Meunier, C. R. 108, 148; 110, 577; A. Ch. [6] 22, 423). In like manner valerio and HClAq form, on shaking, CoH12O4(CbH2O)2, crystallising in prisms, sol. alcohol and ether. Sorbite may be exidised to glucose by heating in sealed tubes with brominewater at 60° and treating the product with Pb and PbO (Vincent a. Delachanal, C. R. 111, 53).

SORDIDIN C16H18O7. [180°]. A neutral crystallisable substance occurring in the lichen Zcora sordida (Paterno, J. 1875, 863). Insol.

water, v. sol. alcohol and ether.

SPARTEINE C₁₃H₂₈N₂. Mol. w. 234. (811° at 723 mm.) (Bamberger, A. 235, 368). [a]_D = -14·6° at 26° (Bernheimer, G. 13, 451). Occurs in the common broom, Spartium scoparium (Stenhouse, A. 78, 1; Mills, C. J. 15, 1). Prepared by extracting the plant with water acidulated with H₂SO₄, evaporating, and distilling with NaOHAq. The distillate is acidified by HCl; evaporated to dryness; and the residue distilled with solid KOH. The base is finally rectified over sodium. Heavy oil, with peculiar odour and bitter taste, sol. alcohol and ether, insol. benzene and ligroin (Houdé, Fr. 25, 568). Lævorotatory. Turns brown in air. Alkaline in reaction. Narcotic poison.

Reactions.—1. Yields (γ)-methyl-pyridine on distillation with lime (Ahrens, B. 21, 826).—2 HIAq at 200° yields MeI and C₁,H₂₄N₂ (276°), which forms a platinochloride [280°], an aurochloride [157°], and a nitrosamine. -3. On passing the vapour through a red-hot tube it gives pyridine, (γ)-methyl-pyridine, C₂H₄, propylene, NH₄, HCy, and other bodies.—4. H₂O₂ forms a

base O₁H₂₆N₂O₂.
Salts.—The hydrochloride is amor-

water (Oechsner De Coninck, Bl. [2] 45, 181) .-B"2HAuCl. Decomposed by boiling water.-B"HI: tables, m. sol. cold water.-B"H₂ZnI₄. B"Ia: green needles (from alcohol), insol. cold water.—B"H₂SO₄: prisms.—B"2C₆H₃N₃O₇.

Methylo-iodide B"Mel. Trimetric plates;

water), v. e. sol. water and alcohol, insol. Nachaq.—B'EtiHi. Got by heating sparteine with Eti and alcohol at 1000 with Etl and alcohol at 100°. Prisms (from cold alcohol). Not coloured by alcoholic potash (De Coninck, C. R. 104, 513). B"EtClHClPtCl.

Dihydride C₁₅H₂₈N₂. (283°). Got by reducing sparteine with tin and HCl (Ahrens, B. ducing sparteine with tin and HCl (Ahrens, B. 20, 2219). Colourless oil.—B"HCl: very deliquescent needles.—B"H₂PtCl₄. Blackens at 239°.—B"HAuCl., Blackens at 130°.—Piorate. [125°]. Needles, decomposing at 215°.—B"HgCl₂. Oxysparteine C₁₃H₂₁N₂O. [84°]. Formed by oxidising sparteine, and extracting the solution with chloroform (Abrang, B. 24, 1005.—\$28, 2607.)

with chloroform (Ahrens, B. 24, 1095; 25, 3607). White hygroscopic needles, v. sol. water, alcohol, and ether. "Its solution is strongly alkaline. Reduces hot Fehling's solution.—B"H,Cl,4aq. Needles,v.sol.water.—B'HClaq.—B"₂H,P'tCl,4aq. Decomposed at 203°.—B"H.P'tCl,4aq. Needles; decomposed at 223°.—B"HA'uCl,.— Mercury double chloride [58°].—B'HBr 2\frac{1}{2}aq.—P'HBr 3\frac{1}{2}aq.—P'HBr 3\frac{1}{2}aq.—P'errate B'HBr 31 aq. -B'HI aq. -B'HNO, aq. - Picrate

Methyl-iodide of oxysparterne B'MeI. [193°].—B'McCl.—B'MeClHClPtCl, aq. [229°]. POCl, at 150° converts oxysparteme into an oily base C15H22N2 which yields C15H22N22HAuGl

Di-oxy-sparteine $C_{15}H_{26}N_2O_2$. [129°]. Formed by dissolving sparteine in aqueous H2O2 (Ahrens, B. 20, 2220; 25, 3609). Prisms, v. e. sol. water and alcohol, sl. sol. benzene, insol. ether. Alkaine in reaction.—B"H_PtCl_e. Blackens about 285°.—B"HAuCl_e. [c. 146°]. Necdles.—B"HI. [137°].—B'HBr. [147°].—B'H_HgCl_e. [193°].

Tri-oxy-sparteine C₁₅H₂₁N₂O₃. Formed by action of H₂O₂ on oxy-sparteine. Crystalline,

7. sol. water and alcohol.—B'2H2PtClaStaq. B'HAuCl. [137°]. SPECIFIC GRAVITY v. Densities, Relative,

vol. ii. p. 370.

VOLUMES. SPECIFIC The molecular weights of substances when divided by their respective specific gravities, taken under comparable conditions, furnish values which have been termed atomic, molecular, or specific volumes. The specific volume is, therefore, the space occupied by aggregates of atoms, including the interstitial spaces, whose weights are proportional to the molecular weights of the substances.

Objection has been raised against the term 'specific volume' on the ground that, as specific gravity is the weight of unit volume, specific volume should by analogy be the volume of unitweight; hence of late years the term 'molecular volume' has been preferred. The term 'specific volume ' has, however, acquired by definition and use a distinctive meaning. The adoption of the term 'molecular volume' is almost certain to be attended with confusion, owing to the different sense in which it is frequently employed by

physicists and chemists. The specific gravity of solids and liquids, referred to water at 4°, is the weight in grams of the unit volume. If, then, the molecular weight be expressed in grams, we may define the specific volume of a solid or liquid substance as the number of cubic centimetres occupied by this mass.

The specific gravity of a gas is usually referred to hydrogen as unity. It follows, then, from the law of Avogadro that all gases should have the same specific volume. There are a few exceptions to the universal truth of this statement arising from so-called abnormal vapour densities, but the specific volumes of the exceptional substances stand in the same simple relation to the normal value that their molecular weights stand to what analogy would indicate as the normal molecular weight.

Inasmuch as the specific gravity of a substance is affected to a greater or less extent by heat, it is obviously necessary to determine this constant under comparable conditions of temperature-that is, at temperatures at which heat may be supposed to exercise the same effect on the substance. In the case of liquids Schröder suggested that temperatures at which the vapour pressures of the various liquids are the same-as, for example, their boiling-points under a standard atmosphere - should be regarded as comparable.

In the case of solids the effect of temperature is of course much less marked, and hence the specific gravity of these substances is usually taken at the ordinary temperature of the air.

Specific volumes of solids.

The first attempt to trace relationships between the chemical nature of substances and their equivalent volumes appears to have been made by Le Royer and Dumas in 1821 (J. Ph. 92, 408). They sought to determine the equivalent volumes of the elements by dividing their atomic weights by their respective specific gravities, the values so obtained being termed by them atomic volumes. They were led to infer that these volumes formed an arithmetical seriesa supposition which was hardly warranted by the facts then known, and which has since been completely disproved by more accurate observations. This idea of combination among solids in definite volumetric proportion was further developed in 1824 by W. Herapath (P. M., Nov. 1824), who sought to prove that the volume of the oxygen in a metallic oxide bears a simple ratio to that of the metal with which it is combined. Almost simultaneously the same problem was attacked by Karsten (S. 65, 394), and subsequently, in 1830, by Boullay, but with no definite general result.

Ammermüller, however, in 1840, concluded (P. 49, 341; 50, 406) that the specific volumes of compounds containing the same elements in different proportions are either identical or stand to one another in rational proportions. Persoz in his 'Introduction to the Study of Molecular Chemistry,' recognised that equivalent amounts of many bodies of analogous composition occupy the same volume, and he inferred that the specific volumes of all substances are multiples of one and the same number, a conclusion also drawn by Le Royer and Dumas, but which is not supported by facts.

Kopp (P. 47, 188), in 1889, first attempted to

educe general formulæ from which he was able o calculate the specific gravities of certain oxides ind haloid salts, with results which showed, in eneral, a fair agreement with the observed values. In the same manner he calculated formulæ for other anhydrous salts-such as sulphates, carbonates, and nitrates—on the supposition that such salts consist of combinations of oxides and acids, or that they are made up of a radicle, acid plus oxygen. By means of these formulæ he inferred that it is possible to draw conclusions concerning the specific gravity of metals for which this constant is unknown. Kopp, in this memoir, used the term specific volume for the first time, and he defined it as the nolecular weight (Mischungsgewicht) of a substance divided by its specific gravity. He found that the specific volumes of similarly reactive elements -as, for example, chlorine, bromine, and iodine; tungsten, molybdenum, chromium, ron, manganese, nickel, cobalt, &c.—are equal or nearly equal. In other cases—as silver and gold, potassium and sodium—the specific volumes stand to each other in simple relations. Elements which, like barium and strontium, form isomorphous compounds have the same specific volume. Strictly speaking, this law can hold only for those substances which are perperfectly isomorphous. The more nearly the crystalline forms of isomorphous substances are identical, the more nearly will their specific volumes be the same. This is made evident by a comparison of the axial ratios of witherite, strontianite, arragonite, and cerussite; and also of the carbonates of zinc and magnesium (mesitene), the carbonates of iron and manganese, and dolomite and calc-spar. It is seen that there is a direct comparison in the case of the latter compounds between the length of the principal axis a and the specific volume V, such that a 4.789 =0.0127671V, from which it is possible, of course, to deduce the specific gravity of the substance from its crystalline form. It also follows that an increase of specific volume is occasioned by an increase in the length of the axis a. If we heat one of these crystals the density decreases; the axis a must therefore increase in length, while the angle R becomes less obtuse. This fact, indeed, was discovered by Mitscherlich, who found that the specific gravity of calc-

spar decreased in the ratio of 1 to $\frac{1}{1.001961}$ when

calc-spar was heated through 100° . The specific gravity of calc-spar is 2.7220, when a=0.8544 and $R=105^\circ$ of. By heating calc-spar through 100° , the specific gravity becomes 2.7167, or the specific volume changes from 36.73 to 36.80. If we determine the length of the axis a by means of the above formula, we find it to be 0.85672, corresponding to an angle R of 104° 57', or a difference of 3', which closely agrees with that actually observed by Mitscherlich $(P.\ M.\ [3]\ 18, 255)$. Schröder $(P.\ 1840.\ 553)$, starting from the observation of Ammermüller, that equal volumes of the two oxides of copper contain the same amounts of copper and multiple amounts of oxygen, assumed that the volume of the copper, as of the oxygen, is equal in the two substances, but that the amount of the oxygen in the cuprous oxide stands to that in the cupric oxide as 1 to 2.

Hence Schröder drew the general conclusion that the same element can have different specific volumes in different compounds, but that the several values for the specific volumes stand in simple relations to each other. He saw in this hypothesis not only an explanation of the condensation which accompanies chemical union, but also a rational basis for the belief that the specific volume of a compound is equal to the sum of the specific volumes of its components.

Schröder found that if in a series of analogous bodies, AO, BO, CO, the specific volumes of which are known, we subtract from these values the primitive atomic volumes of A, B, and C respectively, we obtain a constant remainder. This he found to be the case with the oxides of lead, cadmium, and zinc, and hence he inferred that the metal in these oxides retains its primitive atomic volume. Kopp assumed that this is equally true of the salts of the heavy metals, but with the salts of the metals of the alkalis and alkaline earths this is impossible, as the specific volumes of the salts are, as a rule, smaller than the primitive atomic volumes of the component metals. He had consequently to assume for these metals a special atomic volume, which however, remains the same in all the salts. He determined these values as follows: Suppose M+R to be a compound of a heavy metal, and m+R the analogous compound of a light one; suppose A to be the known specific volume of M+R, and a that of m+R, B the primitive atomic volume of M, and b that of m.

Then, M + R = A,

and M=B.

Therefore the atomic volume with which R is contained in the compound is A-B, say x.

It is assumed that R retains its value in m+R.

and since m + R = a, and R = x;

therefore b. i.e. the atomic volume of m = a - x. Kopp also showed that the densities of the hydrated oxides, and of a number of hydrated salts, may be calculated with considerable accuracy by assuming certain definite values for water in a state of combination. It ought to be stated, however, in this connexion, that subsequent researches have indicated that Kopp's conclusions respecting the specific volume of water of crystallisation must be slightly modified. Schiff, many years ago, showed that the members of certain classes of hydrated salts have practically the same specific volume. Thus, all the alums have a specific volume of about 277; double sulphates of the form M₂M"(SO₄)₂.6H₁O have a common volume of 207; and all the vitriols-that is, salts of the form M"SO4.7H2Owhether isomorphous or not, have the specific volume 146.

Thorpe a. Watts (C. J. 37, 102, [1880]) have shown that the volumes occupied by the several molecules of water vary with the degree of hydration of the salt. In the case of the so-called magnesian sulphates, the first molecule of water, the constitutional water, or 'water of halhydration' of Graham, occupies considerably less bulk than the remaining molecules; its mean relative value is 10.7. Each additional molecule appears to occupy a gradually increasing volumes. The difference between the specific volumes of

the monohydrate and dihydrate is 18.3; between the volumes of the dihydrate and trihydrate the difference is 14.5; between the trihydrate and the tetrahydrate it is 15.4; and between the hexhydrate and heptahydrate it is 16.2. These observations are so far in harmony with Kopp's general conclusions that in the compounds containing only a small number of water molecules (1 to 3) the specific volume of the water is 12.4; in others containing a larger number of molecules of water (2 to 7) it is 13.4; whereas, in a third class, containing the largest number of molecules of water (from 3 to 10), its mean value is 15.3.

Specific volumes of liquids.

Methods. The specific gravity of the liquid at its boiling-point may be determined either directly or indirectly. Ramsay (C. J. 35, 463 [1879]) devised a simple method by which the weight of a known volume of liquid at its boiling-point may be directly ascertained with approximate accuracy. The vessel containing the liquid consists of a thin glass lemon-shaped bulb of about 10 c.c. capacity. At the upper end of the bulb is a capillary tube, bent into the form of a hook; the lower end is provided with a similar hook of solid glass. The capacity of the bulb is ascertained by weighing it full of water at a known temperature. The bulb is filled with the liquid to be examined, in the usual way, by warming and dipping the capillary neck of the bulb beneath the surface of the liquid. It is not necessary to fill the bulb completely; two or three c.c. of the same liquid are then introduced into the wide tube, and the bulb is suspended within it by thin platinum wire attached to a piece of glass rod passing through a hole in the cork. The wide tube is then heated until the liquid within it boils violently, and it is kept in ebullition so long as liquid drops from the end of the capillary neck of the bulb. The lamp is now removed, and the whole allowed to cool. When cold the bulb is dried and weighed. The specific gravity of the liquid is given by the formula

Sp. gr. =
$$\frac{W'}{1 + (0.00015 \times TW)}$$

in which W' is the weight of the liquid; W, that of the water filling the bulb at 0°; and T the temperature at which the liquid boils; 0.00015 is an empirically-determined, co-efficient required in order to make the volume correspond with the real volume at T.

A somewhat similar method of determining the specific gravity of a liquid at its boiling-point is described by R. Schiff (A.'220, 78). The liquid is introduced into a flask of about 7 or 8 c.o. capacity, provided with a long narrow neck on which is a graduated scale. The capacity of the flask up to the zero point is accurately determined by weighing with mercury, and the value of the scale divisions in fractions of a c.c. is also carefully estimated. The flask is then suspended in the boiling tube; a few c.c. of the liquid under investigation are placed in this tube and heated to boiling. After a few minutes the position of the liquid in the graduated neck is noted, and the flask is withdrawn, wiped, and weighed. The specific gravity

at the boiling-point compared with water at 4° is given by the equation

• $D_4 = \frac{1}{V_t[1 + K(t-4)]}$

in which P = corrected weight of the liquid in the flask,

and V_i = the apparent volume of the liquid at t° ,

K = the co-efficient of expansion of the glass.

It will be noticed that Schiff assumes that the liquid in the flask actually acquires the temperature of the vapour by which the flask is surrounded. Lothar Meyer (v. Neubeck, Z. P. C. 1, 652) has slightly modified Ramsay's apparatus. The bulb is best made of Jena glass, and has the capacity of about 2.5 c.c., and its weight, capacity, and thermal expansion are accurately known. It is filled with the liquid, and is suspended by means of a bent platinised-nickel wire within the flask, the neck of which can be closed by a cork. The flask contains a few c.c. of the liquid under investigation, which, when heated, may if necessary be caused to boil at any desired temperature below the ordinary boiling-point by connecting a side tube with a condenser, pressureregulator, and fall-pump. As soon as the liquid within the bulb has acquired the temperature of the boiling liquid, and no further expansion occurs, the source of heat is removed and the bulb is weighed when cold.

The specific gravity of a liquid at its boilingpoint is, however, most accurately ascertained indirectly, although this method demands far more time and apparatus, and a greater number of experimental operations, than the direct method. The method consists in accurately determining (1) the boiling-point of the liquid; (2) the specific gravity of the liquid at some convenient temperature—best at 0°; and (3) the rate of thermal expansion of the liquid from 0° up to the neighbourhood of its boiling-point. From these data the specific gravity of the liquid at the boiling-point can be readily calculated.

1. Determination of the boiling-point. This is best made in an apparatus so arranged that the inner tube, containing the thermometer, is surrounded by a jacket of vapour from the boiling liquid. The boiling liquid should contain a few scraps of platinum foil or a spiral of platinum wire; or, what is even better, a few short lengths of fine capillary tubing. If the amount of the liquid is very small the bulb of the thermometer should be surrounded with a little fibrous asbestos, as suggested by Ramsay a. Young (C. J. 47, 42). The thermometer reading must, if necessary, be corrected for the emergent column, either by the tables of Rimbach (B. 22, 3072) or by that of Thorpe (C. J. 37, 159), and should be reduced to normal pressure by the method of Crafts (B. 20, 709). The correction to standard atmosphere may, however, be ascertained with approximate accuracy by the formula

$$\theta = (p - 760) \frac{278 + t}{8200}, \text{ or } \theta = (p - 760) \frac{278 + t}{10000}$$

in which θ is the correction, t the observed boiling-point, and p the barometric pressure reduced and corrected.

The first correction is applicable to the

greater number of liquids, the second to water and the lower alcohols (Ramsay a. Young, P. M.

1885, 515).

- 2. Determination of specific gravity. This is most accurately effected, at least for substances which are liquid at ordinary temperatures, by Perkin's modification of the Sprengel apparatus. For liquids which are alterable on exposure to air a bottle with a graduated stem is most convenient. The bottle should be previously filled with dry nitrogen, and a special apparatus, analogous to that used by Thorpe (l.c.) must be employed to transfer the liquid to the bottle. A form of bottle for very viscid liquids has been described by Brühl.
- 3. Determination of thermal expansion. Of the various modes of ascertaining the thermal expansion of a liquid the so-called dilatometrical method is, on the whole, the most convenient. It consists in inclosing the liquid in a vessel of known capacity, shaped like a thermometer, and provided with a graduated and accurately calibrated stem. The instrument is placed in a bath of suitable liquid, the temperature of which can be raised to the desired point, as ascertained by a thermometer; and the height of the liquid in the stem of the dilatometer, and hence its apparent volume at the temperature of observation is noted. A series of such observations at various temperatures up to the neighbourhood of the boiling-point is thus made, from which an expression, say of the form $V_t = a + bt + ct^2 + dt^3$... may be calculated. This expression must now be corrected for the expansion of the glass of the dilatometer (obtained by observations with mercury in the usual manner), and from the corrected expression the volume, and hence the specific gravity, at the boiling-point of the liquid may be deduced.

For details of the mode of carrying out these observations v. Kopp (A. 96, 1 et seq.); Thorpe (C. J. 37, 141).

Thorpe (C. J. 63, 262 [1893]) has devised a modification of the ordinary dilatometrical method, which permits the thermal expansion of a liquid to be determined with much greater ease and rapidity than has hitherto been possible. It obviates the use of large baths, and, by reducing the size of the dilatometers to the smallest limit consistent with the proper degree of accuracy, as determined by the error of a thermometer reading, it avoids the necessity for long stems and the consequent correction for the cooled 'emergent columns.'

Results.—The first accurate determinations of the various physical constants needed to ascertain the specific volumes of liquid substances were published by Kopp in 1855 (A. 96 [1855] 1-36, 153-185, 303-335; A. 100 [1856] 19-38; v. also P. 72 [1847] 1-62, 176, 223-293). Kopp concluded, from the results of a long series of ob-

servations, that :-

(1) The selection of the temperature of equal vapour-pressures as a basis of comparison seemed to be warranted by the fact that regularities are thereby made evident which otherwise are not apparent.

(2) Differences of specific volume are proportional to differences in chemical composition.

(8) Isomeric liquids of the same chemical type have equal specific volumes.

(4) The substitution of hydrogen for an equivalent amount of oxygen only slightly affects the specific volume.

(5) One atom of carbon can replace two atoms of hydrogen without altering the specific

yolume of the compounds.

Kopp further found that the specific volume of a liquid compound was conditioned, not only by the composition, but also by the constitution of the compound. Thus the relative position of an oxygen atom in a molecule affects its specific volume; carbonylic oxygen and hydroxylic oxygen have two very different values. Sulphur, in like manner, would appear to have two specific volumes, depending on its position or mode of combination in a molecule.

Definite values for the specific volumes of carbon, hydrogen, and oxygen were obtained from the following considerations. An increment of CH₂ corresponds to an increase of specific volume of 22. Since C and H₂ occupy the same volume, we have C = 11 and H = 5·5. The replacement of H₂ by carbonylic O is attended by a slight increase in the specific volume. Kopp found that the most probable value for O in this form of combination was 12·2. For hydroxylic oxygen it is 7·8; obtained by subtracting the value for H₂ (11) from the specific volume of water, 18·8. Hence the specific volume of a compound $C_aH_bO_cO'_{d_1}$ where O is carbonylic oxygen and O' is hydroxylic oxygen, may be expressed by the formula

V = 11.0a + 5.5b + 12.2c + 7.8d.

Determinate values for the specific volumes of the halogens-and, with less precision, for phosphorus, arsenic, and antimony, for silicon, titanium, and tin-were also obtained by Kopp. As regards nitrogen it was found that in the amines $N=2\cdot3$. The group CN=28; the group NO, = 33. If, then, carbon and oxygen preserved their ordinary values in these radicles N must possess at least three different values depending on the mode of combination. There is, however, no evidence to disprove the supposition that the values for the carbon and oxygen atoms are not equally affected in these groups. This, indeed, suggests the possibility that compound radicles like CO, HO, NO2, CN, &c. may possess definite specific volumes which are not necessarily the sum of the specific volumes of the component atoms as ordinarily ascertained.

H. L. Buff (d. Suppl. 4, 129) sought to show that the specific volume of carbon, like that of oxygen and sulphur, is affected by its mode of combination-or, in other words, that carbon in unsaturated compounds has a greater specific volume than in saturated bodies-from which he surmised that the specific volume of an element is in general determined by its particular atomic value. Thorpe (C. J. 37, 392) found that isomeric liquids have not invariably the same specific volumes. There is a well-marked difference, for example, between ethylene and ethidene chlorides; indeed, ethylene compounds in general appear to have smaller volumes than those calculated by Kopp's values. Städel has shown that in the series of chlorinated and brominated ethanes and ethylenes, the isomeride of higher boiling-point, i.e. the etaylene derivative, has invariably the lower specific volume.

Since these compounds are all saturated, and the only variable constituent is a monovalent element (Cl or Br), it would appear probable that the specific volume of the halogen is also variable. Isomeric hydrocarbons manifest similar differences, whence it is obvious that either one or both of the elements must have a slightly variable volume, depending on grouping or mode of combination; it may be that the iso-group, like the groups carbonyl, hydroxyl, nitryl, &c., has a special volume, which is not necessarily the sum of the volumes of the component atoms as deduced from Kopp's values. Kopp himself found that the volumes of isomerides were in a number of cases only approximately equal, and in others quite unequal. The term 'chemical type,' used in the sense in which Gerhardt employed it, is not sufficiently distinctive to denote the differences, say, between the normal and iso-compounds, or between aniline and the picolines, and it is questionable whether Kopp would have considered such cases as coming within his rule.

The observed specific volumes of the aromatic compounds are frequently lower than the calculated values. Indeed, our views as to the constitution of the aromatic compounds would lead us to expect that the specific volume of benzene, and the volumes of the derivatives which contain the benzene grouping, would probably be different from the values deduced from observations made for the most part on compounds of totally different constitution. Kopp (A. Suppl. 5, 303 [1867]) showed from Louguinine's observations that while benzene has an abnormally low specific volume, its homologues show the constant increase of 22 for an increment of CH., which is what might be anticipated, since these homologues are produced by the addition (substitution) of methyl, ethyl, &c., to the benzene group. Jungfleisch's observations on the specific volumes of the chlorine substitution products of benzene also seem to show that the positions of the chlorine atoms affect, in a very marked manner, the specific volume of the product (C. R. 64,

911). Further observation has shown that Kopp's conclusion that liquid elements and radicles have the same volume in combination as in the free state is well founded. Thus the observed volume of NO₂=32·0, calculated = 31·5; observed volume of Br = 53·6, calculated = 53·4; observed volume of CN = 28·9, calculated = 28·9. The observed specific volume of Cl from Knietsch's determinations of the specific gravity of liquid chlorine is 22·8; the mean calculated value is 22·7. Kopp surmised that members of the same chemical family would be found to have the same specific volume; observation shows, however, that the specific volumes gradually increase with the increase of atomic mass (Thorne, Lc.).

crease of atomic mass (Thorpe, l.c.).

Schiff (A. 220, 71 [1883]) has concluded that while it is generally true that isomeric compounds have slightly different specific volumes, it is almost invariably the case that the substance possessing the higher boiling-point has also the higher specific volume (compare Städel). In the case of the metameric esters of the fatty acids, it is found that, as a rule, the specific volumes increase with the diminution of the number of carbon atoms in the acidic radicle and with the increase of the carbon atoms in the

alcoholic radicle. At the same time, it would atpear that the differences between the observed and calculated values are mainly due to the alcoholic radicle, the acidic radicle apparently having but slight influence. This is in conformity with Lossen's observations, that while the ethers and acids give experimental values which are almost in exact accordance with Kopp's values, the aldehydes and alcohols show wider variations, methyl alcohol giving too great an observed value, while the others give smaller and smaller values as the amount of carbon increases. It is, however, noteworthy that the differences between the aldehydes and derived alcohols remain almost constant, which is not the case with the aldehydes and acids, where the difference appears to increase with the molecular weight. Hence the differences between the homologous aldehydes are very nearly equal to those between the corresponding homologous alcohols (Lossen). The mode in which carbon is combined in an organic compound has, according to Schiff, a distinct influence on its specific volume; like Buff, he finds that a doubly linked carbon atom occupies a smaller volume than when singly linked. It is, however, very doubtful whether the facts at present known are sufficient to establish this conclusion.

There is, however, good reason to believe that what we call 'specific volume' is not a purely additive property. The specific volumes of sub-stances are, in all probability, affected by many more conditions than those we have hitherto taken cognisance of. The value CH2 = 22 has no other significance than as expressing the average increment in volume in successive members of a homologous series. Indeed, as the physical data increase it becomes doubtful whether even this mean value is correct. It would seem that the value augments as the series is ascended. The relation C = 2H no longer applies to carbon compounds in general. What is true of carbon and hydrogen is equally true of oxygen, whether as carbonylic or as hydroxylic oxygen. No definite or uniform values can be assigned to oxygen such that the specific volume of a liquid compound containing this element can be accurately calculated. The values given by Kopp and others are simply mean values, but the actual volumes are affected by conditions of which, as yet, we have no very precise knowledge and which we have no certain means of measuring. The values for the other elements are, of course, affected by these considerations. Thus the specific volume of chlorine is obtained on the assumption that the values for carbon and hydrogen are constant.

Lossen (A. 254, 42) has devised formulæ which take note, or express the measure, of the influences which affect the uniformity in the values of specific volumes of organic compounds. Those formulæ can only be considered as first approximations, but their value will be evident from the fact that they serve to reproduce the observed values with a greater approach to accuracy than has hitherto been possible. Out of the 407 compounds which furnished the experimental material on which these formulæ are based, the observed molecular volumes of 352 differ by less than 2 p.c. from the calculated volumes. Comparatively few of these differences are to be ascribed to experimental errors. In

the main they are caused by influences of structure and composition which as yet we have no certain means of measuring, such as the effect of substituted chlorine, or the special effect of iso- grouping, or of the ortho-, meta-, or paraposition, &c.

According to Lossen, the specific volumes of the greater number of compounds containing carbon, hydrogen, and oxygen which have hitherto been determined, may be calculated by the formula

Sp. vol.
$$G_n H_m O_p(\mu) = \{10 \cdot 24 \pm x0 \cdot 5\} (n+p) + (5 \cdot 12 \pm x0 \cdot 25m) \pm \frac{1}{4} (n-2)^2 \pm 1 \cdot 4\mu$$

In this equation x denotes a number between 0 and 1, which varies with different homologous series but which is constant for the members of the same series. The sign μ represents the number of hydrogen atoms required to convert the formula into that of a saturated compound. The term $\frac{1}{4}(n-2)^2$ is introduced to compensate for the increase in the value corresponding to CH₂ as the molecular weight increases. Gartenmeister (4. 233, 304) having shown that in the case of the fatty esters the mean increase corresponding to CH₂ is 0.5, Lossen adds the term $\left(\frac{1}{2} + \frac{2}{2} + \frac{3}{2} + \dots \frac{n-3}{2}\right)$,

which he erroneously states is equal to $\frac{1}{4}(n-2)^2$, a number always subsequently employed, but which, as comparison shows, serves to give good agreement with observed values.

For the majority of fatty compounds the formula

 $O_nH_mO_p = 10.45(n+p) + 5.225m + \frac{1}{2}(n-2)^n + 1.5\mu$

gives results agreeing with the observed values. For the alcohols, however, the expression becomes

$$C_nH_mO_p=10\cdot 1(n+p)+5\cdot 05m+\frac{1}{2}(n-2)^2+1\cdot 35\mu$$
.

If it be supposed, as seems highly probable, that for all the members of a series of similarly constituted compounds the same influences are existent, whereby the specific volumes exhibit variations from the additive quantities assumed by Kopp, then we may regard the variable x as a term which takes account, and may be regarded as the measure, of these disturbing influences, and which, though constant for the members of the same series, should, as before stated, vary for other homologous series of compounds (Thorpe a. Jones, C. J. 63, 289).

Schröder regards the specific volume of an element in combination as variable within limits determined by the nature of the chemical compound. In any one compound, however, all the elementary atoms are regarded as occupying either equal or multiple volumes. Hence every specific volume is a multiple of a certain space-unit or stere, the value of which may vary between 6.7 and 7.4, depending on the number, nature, and mode of union of the atoms. Schröder thus obtains his determinate values. The specific volumes of formic, acetic, and propionic acids increase about 22 units for each increment of CH2; in the case of alcohols the increase is about 20 units. volume of formic acid is 41.8, i.e. 2×20.9 ; that of methyl alcohol is 42.8 or 2×21.4 . Hence in formic acid, CH2O2, the O2 occupies the same volume as CH,; and in methyl alcohol, CH,O, the HO has the same volume as CH. In like

manner ethyl alcohol, C_2H_*O , has the volume 62·1, i.s. 3×20 ·7. Since $2 \times CH_2 = 2 \times 20$ ·7, then $H_2O = 20$ ·7. Acetic acid has the volume 63·6, i.s. 3×21 ·2; $2CH_2$ is 2×21 ·2 and $O_2 = 21$ ·2. The volume of acetaldehyde is 56·9, i.s. about 6·6 smaller than that of acetic acid; this would indicate that the substitution of OH by H lowers the volume by 6·6. Since $H_2O = 21$ ·4, it follows that the hydrogen and oxygen in hydroxyl each occupy one space-unit or stere. As $CH_2 = 21$, we find that carbon also occupies one stere or space-unit. Now, from the volume of formic acid which contains 6 steres, it is found on subtracting 3 steres for CH_2 and 1 stere for hydroxylic oxygen, that the carbonylic oxygen must occupy 2 steres.

We obtain, then, the following rule: The number of space-units or steres of the saturated compounds of carbon, hydrogen, and oxygen corresponds to the number of the atoms increased by as many units as there are atoms of carbonylic oxygen present.

If we calculate by means of this rule the steres of the saturated compounds, we find that they vary within narrow limits, and for the most partincrease with increasing molecular weight. In the greater number of cases the values range between 6.9 and 7.2. Ostwald has determined the value of the stere for a large number of saturated fatty compounds, with the following results:—

Hydrocarbons 6:89, 6:99, 6:82, 7:11, 7:23.
Alcohols 7:12, 6:91, 6:77, 6:88, 6:78, 6:78.

681, 6.74, 7.09

Acids . 6.97, 7.06, 7.11, 7.19, 7.24, 7.24;

Esters . 7.04, 7.08, 7.05, 7.14, 7.26, 7.43, 7.45, 7.47.

Aldehydes . 7.11, 7.05, 7.18, 7.01, 7.18, 6.93,

7.27.

In the series of the hydrocarbons, the acids, and the esters, the steres in the cases of the normal compounds increase regularly with increasing molecular weight; in the series of the alcohols the steres decrease up to the third member and then increase. The secondary and tertiary compounds have, as a rule, smaller steres than the normal compounds. Kopp concluded from the approximately equal volumes of the alcohols and corresponding acids that H, and O are volumetrically equivalent; and from the equivalence of the volumes of benzyl and amyl compounds he inferred that Co and H, are mutually replaceable without alteration of volume. Hence he assumed that the hydrogen atom occupies only half the volume of the oxygen or carbon atom. Schröder established the volume equivalence of CH2 HOH, and O'O, and he inferred from the difference in volume between alcohol and aldehyde that hydroxylic oxygen has the same volume as hydrogen and carbon, while carbonylic oxygen has twice the volume. While, then, Kopp assumes approximately $H_{z}=C=O$, Schröder makes H=C=O (Ostwald, Lehrbuch, [2nd ed.] vol. i.

In the case of unsaturated and aromatic compounds, Schröder assumes that each double linkage is attended with an increase of volume amounting to one stere; hence the above rule has to be modified in this sense when applied to compounds of this class. The value of the stere

in a number of unsaturated compounds is found

. 6.87, 7.09, 6.93, 6.99. Hydrocarbons Alcohols 6.72.

Esters and ethers . 7:14, 7:13.

These values vary, practically, within the same limits as in the saturated compounds.

As regards aromatic compounds, it would seem to follow from the identity in the volumes of benzoyl and amyl compounds, as indicated by Kopp, as well as from the corresponding relation between the isobutyl and phenyl compounds, that C.H. comprises the same number of steres as C.H. - that is, 13. Of these, 5 are occupied by hydrogen; so that the carbon group C, occupies

The values of the stere in a number of aromatic compounds are as follows:

6.85, 6.94, 6.98, 7.00, 6.95, 7.04, Hydrocarbons 7.04, 7.04, 7.06, 6.84

Other compounds 6.91, 6.87, 7.05, 6.97, 7.16, 7.26, 7.50, 7.28, 7.14, 6.96, 7.07.

The value of the stere here also varies within the usual limits; cit is comparatively small for the hydrocarbons (6.8-7.0), larger in the case of the alcohols, and still larger in that of the esters

(7.2-7.5) (Ostwald, l.c.).

There is one consideration which is vital to the whole question, and to which, therefore, a brief reference must be made. It relates to the choice of conditions under which the values we term specific volumes are really comparable. Although Horstmann and Lossen have advanced reasons against the practice, contending that at any other temperature, say 0°, relations similar to those now established are made manifest, it has been the custom, in accordance with Kopp's direction, to compare the specific volumes of liquids at the temperatures of their respective boiling-points under a standard atmosphere. Whether, however, the temperature of the boiling-point, under these circumstances, is a truly comparable condition is open to question. It has been urged by Horstmann that, since what we call atomic volume is the space not merely filled by an atom but also that in which it moves, it is not a priori probable that at temperatures which differ, say by 3000-as, for example, in the case of C_1H_{10} (boiling-point 1°) and $C_{18}H_{38}$ (boiling-point 317°)—these volumes will be the same. Moreover, as pointed out by Bartoli, the boilingpoint cannot in the nature of things be a strictly comparable condition, since it is affected by pressure to a different extent in the case of different liquids. Objections of even greater weight may be urged against the suggestions of Tschermak and Krafft to take the melting-point as a comparable state.

No doubt, theoretically speaking, a valid condition should be when pressure, volume, and temperature are expressed in terms of their critical values. But that certain regularities in the molecular volumes at the boiling-points have, in spite of this, been discovered may be explained, as Guldberg has shown, when we compare the values of T, the absolute boilingpoint, with those of T, the absolute critical temperature; in those cases in which these two constants are known, the ratio $\frac{\mathbf{T}}{\mathbf{T}}$ approximates

to $\frac{2}{8}$. Hence it follows that qualities like molecular volumes, which alter only slowly with temperature, are comparable at the ordinary boiling-points (Z. P 0.5, 374).

It ought, perhaps, to be stated that subsequent observations show that the so-called 'corresponding temperatures' deduced from Van der Waal's generalisations have not that dogree of validity as temperatures of comparison which they were originally assumed to possess. Indeed, the present condition of knowledge warrants the statement that Kopp's original method of comparison is as valuable as any yet indicated (Thorpe, C. J. 63, 775 [1893]). T. E. T. SPECTROSCOPIC ANALYSIS v. PHYSICAL

METHODS, section Optical methods, subsection Spectroscopic methods, this vol. p. 239.

SPELTER. A commercial name for zinc. SPERGULIN (C,H,O2)n. Occurs in the seedcoverings of Spergula vulgaris and S. maxima (Harz, C. C. 1879, 24). Amorphous. Its alcoholic solution exhibits dark-blue fluorescence, which is destroyed by sunshine. A small quantity of potash or Na₂CO₃ added to the al-coholic solution causes it to fluoresce green. Conc. H₂SO₄ forms a dark-blue liquid.

SPERMINE $C_{10}H_{20}N_4$ (Poehl, B. 24, 359); $C_4H_{10}N_2$ (S.). Occurs as phosphate in the spermatic fluid, in calves' liver and heart, and in some pathologic preparations that have been kept under alcohol (Schreiner, A. 194, 68). It is not identical with pyrazine hexahydride (Majert a. Schmidt, B. 24, 241; cf. Ladenburg, B. 20, 442; 21, 758; Poehl, C. R. 115, 515; Duclaux, C. R. 115, 155, 549). Crystals (from alcohol), v. sol. water, v. sl. sol. alcohol. Alkaacconory, v. soi. water, v. si. soi. acconor. Alkaline in reaction. Absorbs CO₂ from the air. Its aqueous solution is ppd. by phosphomolybdie acid and by potassium bismuth iodide. — C₁₀H₂₀N₄H₄HCl: prisms, v. e. sol. water. — C₁₀H₂₀N₄2H₂PtCl₈.— C₁₀H₂₀N₄4HAuCl₄.— C₁₀H₂₀N₄(H₂PO₂)₂6aq: [170°]; rosettes of pyrawided as bot water. mids, sl. sol. hot water.

SPIKE 01L. S.G. above 900. Slightly dextrorotatory (Schimmel, Ph. [3] 22, 329). [a]_D = 1° 24' (Voiry a. Bouchardat, C. R. 106, 551) or laworotatory (Bruylants, J. Ph. [4] 30, 139). An essential oil obtained from the blossoms of Lavandula aspica latifolia (Lallemand, A. 114, 197; Sauer a. Grünling, A. 208, 75). Smells like lavender. Contains a terpene (175°) or (158°), which yields crystalline C₁₀H_{1s}HCl, camphor, borneol, and a resin. According to Voiry and Bouchardat, oil of spike contains inactive spikol $C_{10}H_{10}O$ [0°] and $C_{10}H_{10}$ (155°-160°) [a]_D = 24°, which yields a hydrochloride [129°] [a]_D = -2°.

SPIROGRAPHIN v. PROTEÏDS, Appendix C. SPONGIN v. PROTEÏDS, Appendix C.

STACHYDRIN C,H15NO2. [210°]. Occurs with glutamine, tyrosine, and stachyose in the tubers of Stachys tuberifera (Von Planta a. Schulze, B. 26, 939). Colourless, deliquescent crystals (from water). Behaves like betaine with regard to alkaloidal reagents.—B'HCl. Prisms, v. sol. water, sol. cold water (difference from betaine).—B'2H.PtCl22aq. Trimetricorystals; a:b:c=:608:1::828.—B'HAuCl2. Small yellow prisms (from water).

STARCH. 508

STACHYOSZ C_{1.}H_{2.2}O_{1.5} Saq. [a]₀ = 148°. Ocours in the roots of Stachys tuberifera (Planta a. Schulze, B. 28, 1692; 24, 2705). Tablets, with sweetish taste, v. sol. water. Destrorotatory. Has no action on Fehling's solution until after boiling with mineral acids, by which it is converted into galactose and an isomeride (? glucose). HNO₂ forms mucic acid, galactose, glucose, and cane-sugar. Gives a red colour on heating with resorcin and HClAq. Gives no pp. with lead acetate until NHAq is added.

STANNATES, and salts related thereto; v. under Tin.

STAPHISAGRINE v. DELPHININE.

STARCH. Amylum. $nC_{12}H_{20}O_{10}$. The value of n has not been definitely settled; it is undoubtedly high. Brown and Morris (C. J. 55, 462), employing Raoult's method for determining molecular weights, show n for soluble starch (see below) = 100, i.e. molecular weight = 32,400. The molecular weight of starch cannot be less than this. From O'Sullivan's work (C. J. 35, 783) it would seem that n is not less than 36. Pfeifer a. Tollens (B. C. 1882, 775; A. 210, 295), from the composition of some sodium and potassium compounds prepared from starch, arrive at the value n=2; the substances are probably compounds, not of starch, but of some decomposition products thereof. Sachsse (C. C. [3] 8, 732) and Nägeli (A. 173, 218) proposed 6C₈H₁₀O₈ + H₂O₈ sthe formula. Other observers (Mylius, B. 20, 694; Salomon, J. pr. [2] 28, 82) have suggested different formulæ, but the evidence is not satisfactory; we may take it, however, that the molecule of starch is not less than n = 100.

Occurrence.—Statch is present at some time or the other in all green plants. It is said to be found in almost all parts of the plant, but it is specially stored up in seeds, the pith of stems, in bulbs, tubers, rhizomes, and roots—generally those parts of the plant which serve as a store for reserve material. It is, however, a question whether the granules recognised as starch in leaves, sap, &c., outside the reserve organs, are chemically identical with the starch of these organs. The evidence, one way or the other, is unsatisfactory. Starch is not known to be an animal product. It is present in some fungi (Bourquelot, J. Ph. [5] 24, 197).

Formation.—Starch has not been prepared artificially. It is produced in the chlorophyll cells of plants, light, carbon dioxide, and water being necessary; oxygen is eliminated at the same time. No doubt, intermediate products—amylan-like bodies, sugars, &c.—are at first produced, but the granules are the first visible products of the assimilation found in the leaves. The starch thus formed is transferred to the reserve organs as such, or, more probably, as some sugar or other transformation product or products, as leaves are known to contain transforming agents (Baranetzky, Die stärkeumbildenden Fermente in den Pfanzen, Leipzig, 1878; Brasse, C. R. 99, 878).

Preparation.—Starch of commerce is prepared from various sources—viz., amongst others, wheat, rice, maize, potatoes, Maranta indica (American starch), Maranta arundinacea (arrowroot), the roots of Jatropha Manihot or Manihat utilissima (tapioca), the stems of several species of Sagus or Oycas (sago). For manufacturing methods see Thorre's Diotionary, art. 'Starch.' In the laboratory, starch can be prepared from any starch-containing material as follows:—

From materials that can be ground, such as the cereals, &c., wheat, barley, maize, rice, &c. The material is ground in a coffee-mill, and the meal steeped in a 0.6 to 1 p.c. sel. KHO or NaHO. After standing 24-36 hours the coarser portions are separated by straining, with rubbing, and a slight flow of water through a wire sieve of about 20 wires to the inch. The strained milky liquid is allowed to stand for a short time, when a layer of crude starch settles at the bottom of the vessel. The liquid, with the matter in suspension, is transferred to another vessel, and again allowed to stand, when a second deposit of crude starch takes place. The process may be repeated a third and a fourth time. The whole of the suspended matter is thus allowed to settle, when the fairly clear supernatant liquid is decanted off and rejected. The deposit is then rubbed through a fine hair sieve, with a slight flow of water, and allowed to deposit a layer of starch as before. This is repeated as long as a starch layer separates. The whole of the starch layers are then collected, again suspended in water, and allowed to settle. At times a layer contaminated with much brown matter falls out first; from this the supernatant liquid with the starch in suspension is decanted off and allowed to stand, when a fairly pure deposit of starch is obtained. Further crops can be got from the residue, but it is difficult to free them from fibre, &c.

From nuterials that cannot be ground, such as potatoes, bulbs, rhizomes, other roots, and pith. The well-washed material is rubbed down with a grater into water, to which atterwards the alkali is added. The first deposit in these cases contains, as a rule, earthy matter, but it is easily separated by allowing it to settle, which it does in a short time, and then decanting off the starchy liquid. Two or three depositions and strainings through a fine hair sieve give a clean starch.

In dealing with the cereals the starch can be separated by what is known as the acid process. The meal is steeped in water and kept at a temperature of from 25° to 27° until acid is developed. On then stirring up with water the light flocculent cell walls and undissolved albuminoids separate and allow the starch to deposit on standing. By repeated suspensions, stirrings, and depositions, clean crops of starch are obtained.

These products, like the starches of commerce, are not pure, but, as a rule, contain ash, oil or fat, albuminoids, &c. Some of them are slightly alkaline, some acid, from the condition of the water used in the last washing. Purification is effected by treatment with dilute KHO solution (0.5 p.c.), then diduct HCl (up to 1 p.c.), then with strong alcohol, and finally with water. They then can be dried by exposure to the air on layers of filter-paper.

Structure.—The starch thus obtained varies much in appearance, from the glistening silky white of potato starch to the dead chalky white of rice or maize starch. It consists of microscopic granules, varying in size from about 0.2

KAA STARCH

mm. to 0.002 mm. The same plant always yields granules of specifically the same size and shape, with as little variation as the size and shape of the leaf, hence, from the microscopic appearance of the granules, it is always possible to tell the source of a sample of starch. If it is wished to determine the source of any sample of starch, the following classification of the starches will be of some use. If, under the microscope, the granules are

(a) large, rounded, and more or less marked with rings: the starch may be potato, tapioca,

sago, &c.

(b) rounded, very slightly ring - marked: barley, rye, wheat, &c.
(c) reniform: beans, peas, &c.

(d) intermediate in size, rounded, and irregular : crocus, tulip, and other bulbs.

(e) irregular in figure, bounded by surfaces more or less plain : maize, oats, rice, &c.

(f) small granules, rounded or irregular:

fern, chestnut, parsnip, &c.
It will be observed that some of these are round, oval, or reniform, while others are irregular figures-bounded by surfaces more or less plain. The microscopic appearance does not always give the true form of the granule. but a form which is the result of the pressure of the cover glass; for example, the well-marked star with central spot in rye starch and the split and striated appearance of maize starch are produced by the pressure of the cover glass on the granules. The granules of some starches are marked with well-defined more or less concentric rings, well shown in potato starch; in others there are no markings, the granules appearing as a clear, transparent cell. It is not absolutely agreed upon whether the starch granule consist of a single body or is made up of two or more. Some hold that the properly purified granule is a single substance, the coating or layers of which differ from the contents simply in containing less water and being thus more dense. According to Nägeli (Die Stärkekörner) and others, the dense portions consist of starch cellulose, while the less dense, transparent plasma is granulose. The stratified structure is the result of the mode of growth of the starch granule, the additions being made by intussusception, i.e. from within outwards. It is said that when the granule is ruptured the granulose dissolves in cold water, leaving the starch cellulose; the former gives the well-known blue reaction of starch with iodine, while the latter is only coloured yellowish (Jessen, P. 106, 497; J. pr. 105, 65; Brown a. Heron, C. J. 35, 610; Brukner, M. 4, 889). On heating the insoluble portion with water it also gives the characteristic blue reaction with iodine. Granulose may be separated from starch cellulose (a) by digesting the granules for several days with a saturated solution of NaCl containing 1 p.c. HCl—the cellulose remains undissolved (F. Schulze, Henneberg's Jour. Landwirth., new ser., 7, 214); (b) by digesting starch with saliva at 45°-55°, this dissolves the granulose (Nägeli, Die Stärkekorner, 110; (c) by the action of certain schizomycetes, which decompose the granulose of starch-paste and leave the cellulose untouched (Fitz, B. 10, 282); and (d) by the action of malt-extract on starch paste in the cold, the cellulose is left undissolved.

A. Mayer (C. C. 1887, 6; Bot. Zeit. 1886, 698) considers that the starch granule is a homogeneous substance, and that the terms 'granulose' and 'starch cellulose' must be abandoned, for he points out that the delicate transparent skeletons left when the gelatinised granules are acted on by saliva, dilute acids, &c., are produced by the action of the reagent on the starch, and are identical with amylodextrin. I am inclined to the view that starch granulose differs from starch cellulose in being less dense in consequence of containing less water of hydration. Starch granules act on polarised light, and when examined with the microscope between two Nicols. produce very pretty effects; v. Bailey (P. M. [5] 2, 123).

Properties .- Air-dried starch sometimes contains over 20 p.c. H.O; this it loses, slowly towards the end, in a vacuum over sulphuric acid; by gradually raising the temperature to 100°, under these conditions, it soon becomes absolutely free from H₂O. The specific gravity of air-dried starch varies very considerably, the variation being due in the main to the quantity of moisture. Dry starches, however, would appear not to be absolutely alike in specific gravity; that of anhydrous potato starch is 1.650, whilst anhydrous arrowroot starch is 1.5648 (Flückiger, Fr. 5, 305; Saare, J. 1884, 1654). Dry starch takes up water, with the evolution of much heat. It does not dissolve in H.O, and has neither taste nor smell.

(a) Action of heat. Dry starch is not coloured at 100°, and, indeed, the temperature can be increased considerably beyond that point without being changed. Starch containing water is, however, coloured by a moderately low temperature, and if the heat be increased to 160° a soluble product is obtained which is known as dextrin or British gum. It is a mixture of undescribed composition. The action of heat on dry starch has not yet been accurately recorded. When the heat is increased beyond 160°, and destructive distillation begins, carbon dioxide, gaseous hydrocarbons, water, acetic acid, and an empyreumatic oil are evolved, and finally a carbonaceous porous cinder is left.

(b) Action of water. As long as the granules are uninjured, starch is insoluble in cold water; when, however, the water is heated, the granules swell up, and a gelatinous, more or less transparent mass, known as starch-paste, is produced. This varies in transparency with the starch employed, as does the temperature at which the gelatinisation takes place. E. Lippmann (C. C. 1861, 859; J. pr. 83, 51) gives the following table on this point:

Source	Swelling-up temp.	Commencement of gelatinisation	Perfect gelatinisa- tion
Rye	45°	50°	55°
Maize	- 50°	55°	62·5°
Barley	87·5°	57·5°	62·5°
Potato	46°	59°	62·5°
Rice	54°	59°	68°
Wheat	60°	65°	67·5°

If the paste is sufficiently dilute it can be filtered, but it is doubtful if the filtrate is a true solution (Picton a. Linder, C. J. 61, 156). The consistency or stiffness of starch-pastes, containing the same amount of dry starch, seems to

vary with the variety of starch employed, and, indeed, with the method of preparation, even with the same starch; but I feel inclined to think that if closer attention were given to the amount of dry starch and its purity much of this apparent difference would disappear. On the relative stiffness of flour or starch pastes, and the mode of estimating it, see Thomson (S. C. I. 1886, 143). If the paste be heated under pressure to temperatures above the boiling-point, maltose and dextrin are said to be produced, but the change has not been accurately studied.

(c) Action of glycerol. Starch heated with glycerol to 190° is dissolved; alcohol ppts. soluble starch from the solution. If the heating be continued at 200°, dextrins are formed (Zulkowski, B. 13, 1895; 23, 3295; C. C. 1888, 1000).

(d) Action of acids. Moderately strong HCl in the cold converts starch, in a few days, without changing materially its microscopic appearance, into a modification perfectly soluble in water. This body is identical with soluble starch prepared by the limited action of malt extract on starch paste (C. Lintner, J. pr. 34, 378; Brown a. Morris, C. J. 55, 450). Prolonged action of 12 p.c. HCl in the cold produces amylo-dextrin (Nägeli, Beiträge z. Kenntniss d. Stärkegruppe; Brown a. Morris, C. J. 55, 450). Boiling dilute acids convert starch, first into soluble starch, then into dextrin and maltose, intermediate products, amyloins, are said to be formed (Brown, Morris a. Moritz, E. P. No. 1809 of 1889), and finally dextrose. The complete conversion takes place the more quickly and perfectly the higher the temperature and the longer the period of the reaction (Allihn, J. pr. 22, 46; D. P. J. 250, 534). This is only accomplished by employing diluted acid. Carbonic acid, oxalic acid, &c., act like HCl and H₂SO₄, but less energetically. For the manufacture of dextrose (glucose) from starch, vide THORPE'S DICTIONARY. The action of acids has been studied chiefly by Kirchhoff, Guérin-Varry, Payen (see Gm. K.), Musculus (A. Ch. [3] 60, 203; J. pr. [2] 28, 496; Bl. 30, 4;; O'Sullivan (C. J. 25, 581); Musculus a. Gruber (C. R. 86, 1459; Bl. [2] 30, 51); Bondonneau (C. R. 81, 972); Salomon (J. pr. [2] 25, 348; 26, 342; 28, 32 a. 122); Sachsse (C. C. [3] 8, 732); Schulze (J. pr. [2] 28, 311); Sostegne (G. 15, 376); Seyberlich a. Trampedach (C. C. 1887, 376); Nigeli (Stärkegruppe, Leipzig, 1874, 83, 99). As a summary of this work it may be stated that dextrose is the final product, but that acids act on this, to some extent yielding products still imperfectly investigated; that intermediate substances, dextrin and maltose and compounds thereof, are first produced; that the rapidity of the change varies with the strength of the acid, with the temperature, and with the pressure at which the change is effected, the most complete and perfect production of dextrose resulting when the conversion is hastened under pressure in presence of a small percentage of acid, 11 to 2 p.c. or less, and the proportion of dry starch to dilute acid does not exceed 1 to 3. Gallasin (C. Schmitt a. Cobenzl, B. 17, 1000; Rosenbek, B. 17, 2456), a gummy body, is found in commercial glucose. This is identical with isomaltose obtained by Fischer (B. 28, 3687) by the setion of strong HCl on dextrose (Scheibler a. Mittelmeier, B. 24, 301).

Action of diastase (malt extract). Diastase does not act on ungelatinised starch in the cold (O'Sullivan, C. J. 80, 133; Brown a. Heron, C. J. 35, 596), but Kjeldahl has shown that this is not true of all starches. This is probably due to some condition of the starch connected with the state of ripeness of the material whence it was obtained. The action, and the products thereof, of diastase on starch paste has been the subject of much study, but as yet only the broad facts are agreed upon. When starch paste is heated to 60° or thereabouts, and a little prepared diastase solution or cold water extract of malt added, the pastiness begins immediately to disappear, the solution rapidly loses the power of giving a blue colour with iodine. and acquires, for a short time, the property of giving with that reagent a deep reddish-brown colour. This, too, it rapidly loses if the diastase is in sufficient quantity. The solution is then perfectly clear when some starches are employed, with others there is more or less flocculent suspended matter in a clear solution. In the cold this dissolution takes place slowly. So far the reaction can be followed with little trouble, but when it comes to a question of the products of the action, the subject becomes more difficult. Musculus (A. Ch. [3] 55, 203) states that when diastase dissolves starch paste at 70°-75°, the products consist of 1 mol. sugar and 2 mols. dextrin, and that no further action takes place. Payen (A. Ch. [4] 4, 286) asserts that more than 50 p.c. of the solid matter dissolved by the reaction is sugar, and says (A. Ch. [4] 7, 382) that four samples taken from an operation in the space of $1\frac{1}{2}$ hours contained 17.9, 20.9, 25.8, and 26.03 p.c. sugar on the total solids dissolved. Schwarzer (J. pr. [2] 1, 212) agrees with Musculus in finding equivalent quantities of dextrin and sugar in solution, but differs from him in supposing that dextrin is formed first, then sugar, and that the action ceases when definite equivalent proportions are produced. He says less sugar is produced at 65° than at lower temperatures; above 65°-70° the proportion of sugar to dextrin is as 1 eq.: 3 eqs.; below 60°, when the principal phase of the reaction is finished. the dextrin and sugar are in the proportion of 1 to 1. The change was considered complete when the solution no longer gave a colour with iodine. These investigators took the sugar as dextrose and estimated the dextrin by difference. O'Sullivan (C. J. 25, 581; 30, 137) showed that the sugar produced was not dextrose but maltose, and that the method of estimating the dextrin was wrong. He also demonstrated that dextrin and maltose were the invariable products of the transformation, and that by continuing the action the whole of the dextrin could be converted into maltose. It was, however, indicated in this work that another body-from which it was impossible to eliminate the cupric reducing power, and which seemed to be a mixture of maltose and dextrin-was amongst the products. Although this work laid the foundation of all that has since been done in the transformation products of starch, it received for a time no attention from the Continental chemists. Musculus (Bl. 22, 32) states that the saccharification of starch paste with diastase ceases when half the matter in solution is sugar. He attri-

butes his original impression that only one-third was converted into sugar to the varying structure of the starch granules, the coating of one variety offering a greater resistance to the action of the diastase than that of another. He still holds that the action is a molecular splitting-up of the starch molecule, attended with hydration, into dextrin and sugar. Bondonneau (C. R. 81, 1212) concludes that the action is not a splitting-up, but that the starch molecule must pass through four isomeric modifications, viz., amylogen [α]_D = +216°, α-dextrin = +186°, β-dextrin = +176°, and γ -dextrin = +164°, before it arrives at the end-product, glucose. These bodies increase in cupric-reducing power as they descend to the final product. Petit (Bl. 24, 519) mentions, as a constituent of the transformation products, a sugar soluble in alcohol, fermentable, and without action on alkaline copper solution. This is, undoubtedly, to be traced to the fact that maltose does not reduce as much copper oxide as dextrose. O'Sullivan (C. J. 30, 125; 35, 770) showed conclusively when working under clearly-defined conditions that maltose and dextrin were the only products of the action, although, as stated, he pointed out the presence of a body which gave a reduction with copper oxide equal to 9-10 p.c. dextrose. The opticity of this body ([a]_j = $+204^{\circ}-206^{\circ}$) was such as to indicate a mixture of 12.3-15.3 p.c. maltose from the reduction, and the remainder dextrin. He concluded that if the amount of reduction of the products be calculated as maltose, and the opticity due to this be subtracted from the total opticity observed for them, the remainder will agree with the activity of an amount of dextrin obtained by subtracting the determined maltose from the total products. He further showed that: (a) malt extract begins to dissolve starch at the temperature of gelatinisation, or a few degrees lower; (b) perfectly gelatinised starch is almost completely dissolved in the cold (10°-20°); (c) at 63° the action takes place according to the equation

A.
$$C_{18}H_{30}O_{18} + OH_2 = C_{12}H_{22}O_{11} + C_6H_{16}O_8$$
; Starch $Maltose$ Dextrin (d) at 64° - 70° to B. $C_{18}H_{30}O_{15}$ $+ OH_2 = C_{12}H_{22}O_{11} + 4C_8H_{10}O_5$; Starch $Maltose$ Dextrin (e) at 70° - 71° $(C.~J.~1879)$ to B^* . $C_{72}H_{120}O_{26} + 3OH_2 = 3C_{12}H_{22}O_{11} + 6C_6H_{16}O_5$; (f) and 71° - 75° to $C.~C_{72}H_{120}O_{26} + OH_2 = C_{12}H_{22}O_{11} + 10C_6H_{16}O_5$; (g) and he stated that although the proportions

(g) and he stated that although the proportions of maltose and dextrin indicated by these equations are easily obtainable when the strict conditions are adhered to, it was only necessary to vary the proportions of malt extract and starch, and time and temperature, to obtain with ease products containing from 16 to 92 p.c. maltose. It is further pointed out that the final product, maltose, was very slowly converted into dextrose by some samples, at least, of malt extract. O'Sullivan (C. J. 85, 770) showed that soluble starch was the first product of the action, and that the changes afterwards brought about may be styressed:

B.
$$C_{72}H_{120}O_{60} + 2OH_2 = 2C_{12}H_{22}O_{11} + C_{48}H_{50}O_{46}$$

B'. $C_{72}H_{120}O_{60} + 3OH_2 = 3C_{12}H_{22}O_{11} + C_{38}H_{50}O_{66}$
 $C_{72}H_{120}O_{60} + 3OH_2 = 3C_{12}H_{22}O_{11} + C_{38}H_{50}O_{56}$
 $C_{72}H_{120}O_{60} + 4OH_2 = 4C_{12}H_{22}O_{11} + C_{24}H_{40}O_{26}$
and finally:
 $C_{21}H_{10}O_{20} + 2OH_2 = 2C_{12}H_{22}O_{11}$.

From the action of malt extract on these products he concluded that it is possible that only one β-dextrin exists. The theory of splitting up and breaking down of the starch molecules, as represented by the equations, does not account for all the facts eliminated. A theory which arranges all the molecules in solution in groups, dependent one on the other-and capable, therefore, of undergoing a simultaneous change, on of being moved at the same time-and the re-arrangement of these groups attendant upon the hydration of a definite proportion of the molecules in each of them, is more in accord with the eliminated facts. Märker (L. V. 22, 69) states that at 60° four molecules starch yield three of maltose and one of dextrin, at 65° there is less maltose, and at a higher temperature two molecules starch yield one of maltose and one of dextrin. Musculus and Gruber (Bl. 30, 54) look upon starch as a polysaccharide containing at least five times the group C12H20O10. When this is acted upon by diastase, or dilute acids, it is broken down with hydration into maltose and a dextrin containing a C12H20O10 group less than starch; that this dextrin is broken down in the same way, maltose and a dextrin containing a C12H20O10 group less than the first one, and so on through the series by successive stages, until finally the solution contains only maltose. They point to the existence of three dextrins giving no reaction with iodine, and call them a, β , and γ achroo-dextrins. From the optical activity and K they attribute to these bodies, they do not agree with O'Sullivan; these factors do not agree with those of a mixture of maltose and dextrin. Brown and Heron (C. J. 35, 596) have eliminated out of the possible varying proportions of maltose and dextrin indicated by O'Sullivan eleven distinct transformations: viz. soluble starch, erythro-dextrin a and β , achroo-dextrins a to η , and maltose. They agree with O'Sullivan that the dextrins are without action on alkaline copper solution. and that the dextrins and maltose are the only products of the reaction. They do not mention the body from which O'Sullivan could not eliminate the reducing power, and they did not observe dextrose amongst the final products with malt extract. They agree with him that the higher the temperature at which the transformation takes place the less maltose is found amongst the products. They represent the normal reaction taking place between 10° and 60° by the equation

 $10O_{12}H_{20}O_{10} + 8H_{2}O = 8C_{12}H_{22}O_{11} + 4C_{6}H_{10}O_{3}$ Starch Maltose Dextrin

They consider the starch molecule to be at least $10C_{12}H_{20}O_{10}$, and that the hydrolysis of it begins by the formation of maltose and erythro-dextrin a, containing $9C_{12}H_{20}O_{10}$; that this, in its turn, yields maltose and erythro-dextrin β , $8C_{12}H_{20}O_{10}$, and so on to the end—product, maltose, They thus agree with Musculus and Gruber as to the

character of the action, but disagree with them is to its quantitative nature.

Herzfeld (B. 12, 2120; 13, 3469) agrees with O'Sullivan and others that erythro- and achroo- dextrins are without reducing power on copper solution, but he points to the presence of a substance amongst the transformation products which seems to hold a position between dextrin and maltose; he names it malto-dextrin. K=about ½ maltose, [a]₁ = +171.6°; thus K corresponds to 33.3 p.c. maltose. A mixture consisting of one-third maltose and two-thirds dextrin would have an opticity [a]₂ = +199°; hence this contradicts the statement of O'Sullivan, confirmed by Brown and Heron, that, taking the reducing power as maltose, the opticity of the remainder of the transformation products corresponds to dextrin. Herzfeld considers that Bondonneau's \(\gamma\)-dextrin is maltodextrin.

Brown a. Morris (C. J. 47, 527) confirm the presence of malto-dextrin, but they show that Herzfeld was dealing with an impure body, and that when its true K and $[a]_1$, viz. K = 211 and $[a]_1 = +193\cdot1^\circ$, are examined it is found that they correspond with a mixture of maltose and dextrin. It is completely converted into maltose by malt extract at 50° to 60°. They do not agree with Herzfeld that it is a hydration product of dextrin, but hold that it is produced from starch and the polymeric dextrins by the fixation of a molecule of water upon the ternary group $(C_{12}H_{20}O_{10})_3$, thus $\left\{ \begin{matrix} C_{12}H_{20}O_{10} \\ (C_{12}H_{20}O_{10})_3 \end{matrix} \right\}$. They have discarded the series of equations, and consider that equilibrium is attained when a condition of things represented by the equation

 $10C_{12}H_{20}O_{10} + 8H_{2}O = 8C_{12}H_{22}O_{11} + 2C_{12}H_{20}O_{10}$ Starch Maltose Dextrin is arrived at. This is always the result when the change takes place at 50° to 60°, or when a higher transformation-product is degraded at that temperature. This degradation is due to the hydrolysis of the more complex polymeric dextrins and malto-dextrin. Bourquelot (C. R. 104, 576) looks upon the action of diastase on starch as a successive fixation of a water molecule with the production of maltose and a lower dextrin until the reduction of the degraded products is K=51.52 (about 82.5 p.c. maltose), but he does not describe his dextrin or dextrins, and he concludes, as has already been clearly proved, that heat alters, not alone the quantity of diastase, but the quality.

Brown and Morris (C. J. 55, 462), from determination of the molecular weights of some of the transformation products, conclude, as suggested by O'Sullivan in 1879, that the dextrins are metameric, and not polymeric, as they hitherto considered them. They therefore abandon their former theory of the hydrolysis of starch by disatase, and, as far as I can see, come to a broad agreement with the theory enunciated by O'Sullivan. They mention another product, amylo-dextrin, $[a]_1 = +206^\circ$, $K = 9^\circ$ 0. Like malto-dextrin, it appears to be a compound of maltose and dextrin, $\{C_{12}^{14}H_{22}^{-0}O_{13}\}_{s}^{1}$. Its opticity and K agree with the body described by O'Sullivan in 1872, and mentioned above.

A new phase has been given to the trans-

formation by C. J. Lintner (Zeit. ang. Ch. 1892, 263). He says he has isolated a body, which he calls isomaltose, from amongst the products. It is less fermentable and less soluble in alcohol than maltose, with $[a]_D = +139$ and K = 52, the opticity being nearly that of maltose and the reducing power about 84 p.c. thereof. Diastase converts it into maltose completely.

Since the publication of the above Morris a. Wells (Transactions of the Institute of Brewing, 5, 133), and Moritz (ibid. 4, 141) point to the presence of a whole series of amyloins or malto-dextrins amongst what they call restricted starch-conversions, and they assert that isomaltose is a low amyloin—i.e. one in which the maltose constituent largely predominates. These amyloins begin with a high proportion of the dextrin residue, and end with a high proportion of maltose. Their optical activity and reducing power are such as would be yielded by mixtures of maltose and dextrin.

Schifferer (In. Dissertation, Basel) denies in toto the existence of the amyloins, and asserts that nothing is to be found amongst the products of the action of diastase on starch but achroo-dextrin, isomaltose, and maltose. His dextrin, however, is a reducing dextrin; even otherwise, the work will not bear criticism.

Action of other enzymes. Ptyslin (ptyslase). This enzyme of saliva liquefies starch paste (Nügeli, Die Stärkektörner, p. 113; Lefberg a. Georgieski, Bl. [2] 25, 393; Dobroslavine, Bl. [2] 26, 452; Maercker, L. V. 22, 69; Watson, C. J. 1879, 539; Musculus a. De Mering, Bl. [2] 31, 105; Lea, J. Physiol. 11, 226). The products are maltose, a reducing, unfermentable dextrin, and a little dextrose. Ungelatinised starch is not acted upon by ptyslase; at a temperature slightly below the gelatinising point the starch is dissolved, and the action is most rapid when the ferment acts at 60° on previously-boiled starch paste (Bourquelot, C. R. 104, 71 a. 177).

Enzymes capable of dissolving starch have been observed in the pancreatic juice (Brown a. Heron, Pr. 1880, 394), in the small intestine (Hoppe-Seyler, Phys. Ch. 275; Brown a. Heron, l.c.), in the liver (Wittich, Pf. 7, 28; Bernard, C. R. 85, 519; Abele, Th. J. 6, 271), and in many other animal tissues (Ellenberger a. Hofmeister, Th. J. 12, 501; Paschutin, Th. J. 1,304). The stomach, pancreas, and peritoneal lymph of fishes contain an enzyme capable of dissolving starch (Richet, Th. J. 14, 359; Kruckenberg, Unter. Phys. Inst. Heidelberg, 1, 2). Blood contains a diastatic enzyme, for starch injected into the blood yielded maltose and dextrin (Binmerman, Pf. 20, 201; Ploz a. Tiegel, Pf. 6, 249).

Starch-dissolving enzymes exist in the leaves and other parts of most plants (Baranetzy, Die stärkeumbildenden Fermente in den Pflansen, Leipzig, 1878; Vines, Ann. Bot. 1891, 409).

Certain organisms, bacteria, moulds, &c., are capable of secreting an enzyme or enzymes having the power of dissolving starch. The nature of the dissolution products has, as yet, been very imperfectly studied; we have simply the general statement that they are sugar or sugars and dextrin (Wortman, Z. P. C. 6, 287; Fitz, B: 10, 282; Marcons, C. R. 95, 345 a. 856; Gayon a. Dubourg, C. R. 103, 885;

STARCH:

Atkinson, Pr. 82, 299; Takamine, E. P. 5700 a. 17874, 1891). Bacillus amylobacter yields dextrin and a small quantity of a crystalline body (Villiers, C. R. 112, 485 a. 113, 144 a. 536). Under the influence of Bacillus suaveolens, dextrin, glucose, alcohol, aldehyde, formic, acetic, and butyric acids are produced. Amylic alcohol is the result of the action of Bacillus amylosymicus, no doubt intermediate bodies; dextrin and sugar are at first produced. Atkinson states that the moulds grown on steamed rice in the manufacture of saké, in Japan, secrete an enzyme, which first converts starch into dextrin and maltose, and further acts on the maltose and dextrin, with the production of dextrose.

Some gums of the arabin group contain a starch-dissolving enzyme (O'Sullivan, C. J. 1891,

1061).

Maize, malted and raw, and other grains contain an enzyme capable of dissolving starch and yielding as a final product dextrose (Cuisinier, C. C. 1886, 614). Its action on starch is not very vigorous, but it acts more rapidly on dextrin and converts maltose very rapidly into dextrose (Geduld, Wochenschrift f. Brauerei, 8, 620; Lintner, Zeit. f. ges. Brau. 1892, 123). It would be interesting to determine in what respect this enzyme differs from that of the moulds, and to establish their separate existence.

Action of the halogens. Chlorine does not stain starch. Bromine colours it yellow. Iodine gives with it an intense blue. This reaction is a distinctive test for starch. The colour is destroyed by heating, but returns on cooling; but if the solution be boiled for some time, the colour does not reappear. The blue colour is also discharged by arsenious and sulphurous acids, by alkalis and carbonates thereof, and, indeed, alcohol can remove the iodine. A solution of iodine in strong alcohol does not colour dry starch. Some observers consider that the production of this blue colour is not due to a definite chemical combination of iodine with starch (Vogel, N. Rep. Pharm. 22, 349; 25, 565; Pellet, M. [3] 7, 988; Tomlinson, P. M. [5] 20, 168; Duclaux, A. Ch. [4] 25, 264), while others attribute a definite formula to the combination. According to Bondonneau (C. R. 85, 671), it is $(C_6H_{10}O_5)_5I$; Mylius (B. 20, 688) considers it to contain HI, and gives the formula $(C_{24}H_{40}O_{20}I)_4IH$ as probable. He finds that the HI can be displaced by metallic iodides. Stocks (C. N. 56, 212; 57, 183) and Seyfert (Zeit. ang. Ch. 1, 15) contradict this. Rouvier (C. R. 114, 128 a. 1866) attributes the formula (C₆H₁₀O₅)₈I to the compound. Starch is oxidised by chlorine and by bromine to gluconic acid (Habermann, A. 172, 11; Herzfeld, A. 220, 364).

Action of alkalis. Weak solutions of the alkalis do not act on starch in the cold, but solutions containing over 3 p.c. real alkali cause the granules to swell up with the formation of a thick transparent paste, and, finally, a clear solution, a compound of starch with the alkali being formed (Schmidt, A. 51, 81; Ventzke, J. pr. 25, 65) which, according to the latter, is optically inactive, but this, no doubt, is incorrect, for Béchamp (C. R. 39, 653) gives the opticity [a] = +211° for the starch dissolved, and Thomsen (B. 18, 2169) shows that the ac-

tivity of dilute soda solutions is $[a]_D = +168$. On neutralisation this becomes much higher, corresponding, in fact, with Béchamp's number. The product does not reduce alkaline copper solution (Brown a. Heron, C.J. 35, 617). The potassium compound is obtained by ppg. the solution in dilute KHO with alcohol, pressing the pp., dissolving in H_2O , and re-ppg. with alcohol. This process repeated three or four times is said to yield a pure compound of the composition $C_{24}H_{39}O_{30}K$ (Pfeiffer a. Tollens, A. 210, 288). A sodium compound $C_{24}H_{39}O_{30}Na$ has been obtained in the same way (Reichardt, Z. 1870, 404). These formulæ are, however, very improbable. Alcoholic soda does not act on starch (Dragendort, J. f. Landwirthschaft, 7, 2066).

A Proposition of the Proposition of the States

Starch heated with ammonia yields brown, amorphous, nitrogenous bodies (Thénard, C. R.

52, 444).

Fused with KHO, starch, like other carbohydrates, yields oxalic acid, acetic acid, and

other products.

Action of alkaline earths. Barium, strontium, and calcium compounds similar to the sodium and potassium bodies have also been prepared. When solutions of soluble starch are ppd. with solutions of lime in sugar syrup, pps. are produced which are not very definite in composition, the percentage of lime showing a variation between C₈H₁₀O₃CaO and (C₈H₁₀O₃)₄CaO. Similar baryta compounds have been examined. When a solution of soluble starch is saturated with strontia and alcohol added, a strontium compound is ppd. (Lintner, Zeit. f. ang. Ch. 1888, 232). On distilling starch with lime acetone, mesityl oxide, isophorone, and ketones are produced (Harvat, C. C. 1887, 38).

On digesting starch with acetic anhydride, a triacetate is said to be formed $C_vH_1O_2(C_zH_2O_z)$, (Schützenberger a. Naudin, Bl. [2] 12, 110; A. Ch. [4] 21, 235; Michael, Am. 5, 359). This substance is amorphous; it is stained blue by iodine, and is decomposed by alkalis, with the

reproduction of starch.

Qualitative determination. The presence of starch is indicated by the granular appearance under the microscope, and starch granules are distinguished from all others by being stained blue by iodine solution and yellow by bromine. If the plasma in which the granules are contained is alkaline, it must be rendered slightly acid, or sufficient iodine solution must be employed to destroy the alkalinity. A solution of iodine in potassium iodide is usually employed, but an alcoholic solution answers the purpose. When the test is applied for starch in solution, the solutions must be cold and slightly acid and the reagent must be added in small quantities at a time. It is sometimes necessary to test a solution for soluble starch in presence of a-dextrini.e. the dextrin giving a reddish-brown colour with iodine. If this is in excess the reddishbrown colour covers the blue; ammonia added cautiously, drop by drop, discharges the reddishbrown, and if soluble starch be present the blue becomes definite and distinct. Care must be taken to avoid excess of ammonia (O'Sullivan). Small quantities of starch, which would otherwise not be observable, may be detected in the 'last runnings' of malt wort by adding a little

STAROH

511

tannin and then alcohol to the solution. The starch is ppd. in this way, and on washing the pp. with water will yield the characteristic reaction with iodine (Burckhardt, Chem. Zeit. 1877, 1158). Starch, when moistened with an alcoholic solution of a-naphthol and a few drops of warm concentrated sulphuric acid added, acquires a deep violet-red colour (Ihl, Chem. Zeit. 11, 19).

Quantitative determination. There are very few materials containing starch of which a sufficiently accurate average sample can be obtained to render a definite estimation of the starch therein of much value.

In some cases separation of the starch, by one of the methods given for its preparation, gives results of sufficient accuracy to satisfy the requirements.

In the case of potatoes, the percentage of starch is deduced from the specific gravity, a set of specially-constructed tables being used; but this method, on the face of it, cannot yield more than an approximation. The specific gravity of the washed potatoes is taken in the usual way, a balance constructed to meet the requirements of the case being employed. About 5 kilos. of the potatocs are weighed in a strong wire basket in air, and then in water; thence, weight in air

specific gravity = weight in air - weight in water. According to the tables of Behrend, Märker, and Morgan, we have from

	Per cent. of	ŀ	Per cent. of
Sp. gr.	starch	Sp. gr.	starch
1.080	13.9	1.120	22.5
1.090	16.0	1.130	24.6
1.100	18.2	1.140	26.7
1.110	20.3		20 ,

In cases in which fair average samples of the material can be obtained, several methods have been proposed, all depending on the conversion of the starch, or the starch transformation products, into dextrose by digestion with dilute HCl or H2SO4, the dextrose being estimated with Fehling's solution, volumetrically or gravimetrically, and the starch calculated therefrom according to the equation $C_aH_{10}O_a + H_2O = C_0H_{12}O_a$ (v. Sachsse, C. C. [3] 8, 732; Märker, Handb. der Spiritusfabrication, 4 Auf., Berlin, 1886, 93; Soxhlet, Zeit. f. ges. Brau. 1881, 177; Faulenbach, Zeit. f. phys. Chem. 7, 510; Zipperer, Rep. An. Chem. 6, 699). Dubrunfaut dissolved the starch by rubbing the material with concentrated HCl, diluting the solution with water to a certain volume, and determining the opticity. The starch was calculated from $[a]_j = 192.4^\circ$.

Effront (Bl. [2] 47, 5) dissolves the starch with malt extract, determines the optical activity of the solution, then heats it with ammonia, after which he treats it with sodium hypochlorite and with HCl, and again determines the opticity; but this method is open to many objections.

These methods are unsatisfactory, inasmuch as it is difficult, if not impossible, to completely convert starch or starch products into dextrose, there being a probable error at one time from overconversion, at another from under-conversion: and, indeed, both may occur at the same time, the amount of reduction of Fehling's solution taken as dextrose never being a correct measure of the starch transformed. Another objection to the method is due to the fact that dilute acids convert other substances besides starch into bodies capable of reducing copper oxide.

Girard (C. R. 104, 1629) titrates starch with iodine solution, 1 grm. of starch taking up 0.157

grms. iodine.

Asboth (Chem. Zeit. 11, 785) proposes to add an excess of baryta water to the gelatinised starch and then alcohol. The dried pp. contains 19.8 p.c. BaO, the remainder is starch. This method, too, cannot be of any use.

O'Sullivan (C. J. 45, 2) described a method by which starch in most materials can be estimated with accuracy. If a fair average sample of the material cannot be obtained by grinding and powdering alone, it is first dried in warm. dry air and then powdered. The following is the method as applied to the cereals, but it is also applicable to all materials when treated as just described.

Fivegrams, or thereabouts, accurately weighed more if the material contains less than 40 p.c. starch-of the finely-ground material are introduced into a wide-necked flask of 100 to 120 c.c. capacity. To this sufficient alcohol of sp. gr. 0.82 is added to saturate it, and after a time 20 to 25 c.c. ether are introduced. The clear, ethereal solution is decanted off after standing for a few hours, and the residue again treated two or three times with ether. It is then extracted with alcohol, sp. gr. 90, at 35° to 38°, and treated with a large bulk of water, with which it is left in contact for at least 24 hours. If any sign of fermentation shows itself, a little salicylic acid solution may be used with the water. The residue, after being completely extracted with water, together with the filter, through which all the extracts should have been passed, is transferred to a beaker of about 100 c.c. capacity, and made up with water to about 40 to 45 c.c. This is heated to boiling for a few minutes in a water bath, care being taken, by continual stirring, to insure a homogeneous paste; then cooled to 62° to 63°, and 0.025 to 0.035 gram prepared diastase or its equivalent of malt extract added. the digestion being then continued at the temperature stated for a few hours. At the end of that time the contents of the beaker are boiled for a few minutes, thrown on to a filter, and the filtrate received in a 100 c.c. measuring flask. The residue is carefully washed with small quantities of boiling water at a time, and the filtrate made up at 15.5° to 100 c.c. A determination of the reducing power calculated as maltose, and of the remainder of the optical activity as dextrin, gives the data for calculating the quantity of starch. This holds good even though the amyloin theory of the breaking down of starch be proved to be accurate.

Example.- 5 grms. barley-flour treated as described, 0.03 grm. prepared diastase being employed, gave 100 c.c. solution of sp. gr. 1.01008 = 2.539 grms. solid matter. 9.178 grms. this sol. reduced 0.241 grm. CuO. Opt. act. in

If cold-water mait extract be used, a portion of its must be heated for the same time and at the same tem-perature as the assay; then bolled, and the opticity and leducing power determined; these factors calculated on the quantity employed must be allowed for.

519 STARCH.

200 mm. tube = +21-1 divs. (Soleil-Ventzke-Scheibler saccharimeter). Hence

0.241 + 0.7256 (K of maltose = 62.5) = 0.1748 grm. maltose;

9.178 grms.: 101.003 (the wt. of 100 c.c. sol.) ::0.1748 : x;

x = maltose in the 100 c.c. sol. = 1.923; Opt. act. maltose $[a]_j = +154^\circ$ and of dextrin $[a]_j = +222^\circ$.

Hence 1 grm. maltose in 100 c.c. sol. in 200 mm. tube = 8.52 divs. of instrument mentioned, and 1 grm. dextrin under like circumstances = 11.56 divs. Then 1.923 × 8.02 = 15.422 divs. opt. activity of the maltose, 21.1 - 15.422 = 5.678 divs. opt. activity of the dextrin, and 5.678 + 11.56 = 0.491 grm. dextrin in the 100 c.c. sol. Dextrin is derived from starch without any increase of weight: 100 grms. starch yield 105.5 maltose; honce

1.055 : 1.923 :: 1 : x starch - maltose; x = 1.822 grms. starch.

1.822 + 0.491 (as dextrin) = 2.313 starch; in the 5 grms. taken = 46.26 p.c.

It is clearly shown in the paper quoted that if starch is not estimated in the way indicated no reliance can be placed on the results. It happens when dealing with some varieties of material that the aqueous extract contains soluble starch (blue colour with iodine). This cannot be looked upon as starch; it must be estimated in the solution as the soluble modifi-

Soluble starch may be prepared (a) by triturating starch with sharp sand or powdered glass so as to disintegrate the granules and extracting with cold water; (b) by the limited action of malt-extract or of acid.

Delffs (P. 109, 648) prepared soluble starch by triturating starch with sand and water; the solution gave a dark blue colouration with iodine. Flückiger (Z. 1861, 104) prepared a similar solution by acting on starch with a concentrated solution of calcium chloride and treating the resulting gummy mass with water, when, on filtration, a solution is obtained which exhibits all the characteristics of soluble starch. Musculus (Bl. [2] 22, 26; A. Ch. [5] 2, 385) does not consider this a true solution; he prepares the body by boiling starch with very dilute sulphuric acid, saturating the solution with chalk, and evaporating to a syrup. This deposits small granules which gradually increase in size, are soluble in hot water, and may be purified by precipitation with alcohol. It possesses no reducing power; its rotatory power is four times that of glucose. Bondonneau (C. R. 80, 671) has prepared soluble starch by this method, but does not find it altogether soluble under all conditions. Soluble starch is undialysable. Fuming nitric acid converts it into a mononitro-derivative, CaH, (NO2)O3; dilute nitric acid oxidises it to carbonic and oxalic acids; bromine and silver oxide to gluconic acid (Reichardt, B. 8, 1020; 7, 424).

Nägeli (Beiträge s. näheren Kenntniss der Stärkegruppe, Leipzig, 1874, p. 33, 99; A. Ch. 178, 218) gives the following method: 1 kilo. potato starch is allowed to stand 6-8 weeks with 6 litres hydrochloric acid, S.G. 106; this is then purified by solution in hot water; it crystallises in sphero-crystals (Jaquelain, A. Ch. [2] 48, 178). According to Brown a. Morris, this is

not soluble starch (v. above). Zulkowski (B. 18, 1895) prepares soluble starch by heating dry potato starch with glycerol at 180°-190° for half an hour. The solution is cooled, precipitated by alcohol, and the precipitate purified by solution in water and reprecipitation by alcohol.

Salomon (J. pr. [2] 28, 82) finds that soluble starch is the first product of the action of dilute acids on starch; it does not reduce Fehling's solution, and has an optical activity $[a]_0 - 211.5^{\circ}$. O'Sullivan (C. J. 1879, 772) prepares soluble starch by dissolving starch paste at 73°-74° with the least possible quantity of cold water extract of malt, boiling the solution as soon as it becomes clear, filtering, and concentrating. The soluble starch falls out on cooling as a white precipitate, which is purified by dissolving in hot water and allowing to cool when it separates out again. It has a reducing power, 3.5-0.78, and an optical activity $[\alpha]_j = 219.5$ -222.0, the reducing power being probably due to a small quantity of maltose; v. also Action of

acids on starch, above.

STEARIC ACID C₁₈H₃₆O₂. Mol. w. 284. (232° cor. at 15 mm.) (Krafft, B. 17, 1629); (359°-383°) (Carnelley a. Williams, B. 12, 1360). H.F. 126,000 (Von Rechenberg). S.G. (liquid) ⁶⁹ ·845; (solid) ² ·1·01; ¹⁰ ·1·00. S.V.S. 332·6 (R. Schiff, A. 223, 264). S. (alcohol) 2.5 in the cold. S. (benzene) 22 at 23°. S. (CS2) 30 (Vogel, J. 1866, 892). Occurs as glyceryl stearate in very many fixed animal and vegetable fats and oils (Chevreul, A. Ch. 88, 225; [2] 2, 354; 23, 19; Braconnot, A. Ch. 93, 250; Redtenbacher, A. 35, 46; Bromeis, A. 35, 86; 37, 303; Stenhouse, A. 36, 57; Erdmann, J. pr. 25, 497; Francis, A. 42, 256; Gottlieb, A. 57, 35; Laurent a. Gerhardt, A. 72, 272; Hardwick, C. J. 2, 232; Crowder, P. M. [4] 4, 21; Berthelot, A. Ch. [3] 41, 216, 432; 47, 297; Pebal, A. 91, 138; Heintz, A. 92, 295; Johnston, C. J. 29, 8).

Formation.—1. By saponification of cetylocetoacetic ether, obtained from cetyl iodide and sodium acetoacetic ether (Guthzeit, 4.206, 351), 2. By heating cetyl-malonic acid at 150°.—3. From ricinoletic acid by treatment with water, P, and I, followed by zinc and HClAq (Claus, B.9, 1916).—4. By heating oleic acid with iodine (1 p.c.) for several hours at 275° and distilling the product in a current of superheated steam (De Wilde a. Reychler, Bl. [3] 1, 295).

Preparation. - Suet or cacao fat is saponified by NaOHAq, the acids ppd. by H₂SO₂ and crystallised from alcohol. An alcoholic solution of the impure stearie acid (4 pts.) saturated at 0° is heated to 60° and mixed with a boiling alcoholic solution of Mg(OAc)₂ (1 pt.). The ppd. magnesium stearate is boiled with HClAq and the stearie acid recrystallised from alcohol (Heintz). Stearie acid can also be readily obtained from shea-butter which contains no other solid fatty acid (Buff a. Oudemans, J. pr. 89, 215).

Properties.—Pearly plates, insol. water, sol. alcohol and ether. Tasteless and inodorous. May be distilled in vacuo and, in small quantity, under atmospheric pressure, but in this case it is partly decomposed with formation of hydrocarbons, stearone, water, CO₂, acetic acid, and butyric acid. Fusion with P₂O₂ forms Cl₂H₂O₃ [54°-60°]. Nitrie acid forms sebacie, glutarie,

succinio, and other acids. Or and water at 140° form bromo- and dibromo-stearic acids (Oudemans, J. pr. 89, 193). Distillation in vacuo with NaOMe yields C₁₇H₁₆ (Mai, B. 22, 2133). Salts.—KA'. Hygroscopic crystals. S. 4

in hot water. Partially decomposed by a large quantity of water into an insoluble acid salt and free potash.—KHA'₂. Silvery scales (from alcohol). S. (alcohol) 36 in the cold; 27 at 78°. Boiling water converts it into a more acid salt. NaA'.—NaHA'2: insol. water.—BaA'2: minute laminæ, insol. water.—CaA'2.—SrA'2.—MgA'2: minute laminæ (from alcohol).—CuA'2: lightblue amorphous powder.—PbA'2: amorphous powder, insol. ether. —Pb₂OA'2.—AgA': white pp.

Methyl ether MeA'. [38°]. Crystalline, insol. water (Hanhart, C. R. 47, 230).

Ethyl ether EtA'. [33°]. (224°). Formed by heating the acid with alcohol at 200° (Lassaigne, A. 13, 168; Berthelot, A. 88, 312) by passing HCl into an alcoholic solution of stearic acid (Redtenbacher, A. 35, 51) and by heating stearin with a little NaOEt (Duffy, C. J. 5, 197; Bouis, C. R. 45, 35). Crystalline mass, partially decomposed by distillation. V. sol. alcohol.

decomposed by distillation. V. sol. alcohol.

Ethylene ether O.H.A'₂. [76°]. Fro
AgA' and C.2H.Br. (Wurtz, A. Ch. [3] 55, 436).

Isoamyl ether C.H.,A'. [25°].

Octyl ether C.₈H.,A'. [45°].

Getyl ether C.₆H.₃A'. [55°-60°]. Lamin
(from ether) (Berthelot, A. Ch. [3] 56, 70).

Laminæ

Glyceryl ethers v. vol. ii. p. 622. mixture of stearic acid and glycerin saturated with HCl at 100° forms C₃H₃Cl(OH)(OC₁₈H₃₂O) $[28^{\circ}]$

Phenyl ether PhA'. [52°]. (mm.) (Krafft a. Bürger, B. 17, 1380). (267° at 15

p-Tolyl ether C, H,A'. [54°]. (276° at 15 mm.).

Chloride C18H28OCl. [23°]. (215° at 15

mm.). Crystalline mass.

Amide C18H35O.NH2. [109°]. Formed by distilling ammonium stearate at 230' under pressure; the yield being 50 p.c. (Hofmann, B. 15, 984; cf. Carlet, Bl. 1859, i. 76). Formed also by the action of NH, on the ether or on the chloride. Converted by the action of Br and NaOHAq into stearyl-heptadecyl-urea (Turpin, B. 21, 2486).

Anilide C18H35ONHPh. [94°]. by distilling aniline over stearic acid at 230°

(Pebal, A. 91, 152). White needles.

Phenyl hydrazide C_{1,}H₃₅,CO.N.H₂Ph. [107°]. Formed by heating stearic acid with phenyl-hydrazine. White unctuous plates (from alcohol), sl. sol. cold alcohol, benzene, and ether (Strache a. Iritzer, M. 14, 37)

Nitrite C_1H_2ON . [42°]. (275° at 100 mm.). S.G. $\frac{1}{2}$ 815; $\frac{100}{2}$ 779. Formed by distilling stearamide with P_2O_5 (Krafft a. Stauffer, B. 15, 516, 1730) or by heating cyanostearic acid at 250° (Hell a. Sadomsky, B. 24, 2779).

References. - Bromo-, DI - BROMO - IODO-, CHLORO-, IODO-, NITRO-, and OXY-STEARIC ACID.

Isosteario acid (C.H.,),CH.CO,H. [38.5°]. (278° at 101 mm.). Formed from di-octylacetoacetic ether or di-octyl-malonic acid (Conrad a. Guthzeit, A. 204, 11, 165). Colourless leaflets (from alcohol).—NaA': needles (from alcohol). AgA': thick white pp.

Ethyl ether Ei $\mathring{\mathbf{A}}$. (275°-280° at 100 mm.). 70t. IV.

STEARIC ALDEHYDE C.,H.O. (213° uncor. at 22 mm.). Formed by distilling calcium stearate with calcium formate (Krafit, B. 13, 1417). Plates with bluish glitter, sl. sol. ether.

STEARIN v. Stearyl derivative of GLYCERIN. STEAROLIC ACID C18H32O2. Mol. w. 280. [48°]. (260°). Formed by heating bromo-oleis acid or the dibromide of oleic acid with alcoholic potash at 100° (Overbeck, J. pr. 97, 159; A. 140, 49). Needles (from alcohol), insol. water. Br Forms $C_{18}H_{22}Br_2O_2$ and $C_{18}H_{32}Br_1O_2$ [70°]. I and FeI₂ in CS₂ form $C_{18}H_{32}Br_1O_2$ [51°] (Liebermann a. Sachsse, B. 24, 4116). Potash-fusion yields myristic acid $C_{18}H_{28}O_2$ and an acid $C_{18}H_{39}O_3$ [21°] (Marasse, Z. [2] 5, 571; B. 2, 359). Alkaline KMnO, oxidises it to subcric and stearoxylic acids (Hazura a. Grüssner, M. 9, 952). HNO, yields . azelaic, stearoxylic, pelargonic, and nitrosopelargonic acids (Limpach, A. 190, 294). Phenylhydrazine at 140° gives C₁,H₃,CO,N₂H₂Ph [82°] (Holt, B. 25, 2670).—BaA₂,—CaA₂ aq.—AgA'.

STEARONE (C₁,H₃),CO. Di.heptadecyl

ketone. [88°]. S.G. (liquid) 43 7979 (Krafft, B. 15, 1715). Formed by heating stear; a acid (9.5 g.) with P.O. (5g.) at 210° (Kipping, C. J. 57, 537; cf Bussy, A. 9, 269; Redtenbacher, A. 35, 57; Varrentrapp, A. 35, 80; Rowney, C. J. 6, 97; Heintz, P. 94, 272; 96, 65). Got also by dis-tilling the stearyl derivative of heptadecyl-urea with lime (Turpin, B. 21, 2486). Plates, sl. sol. hot alcohol. Br forms C₃, H_{ak}Br₂O [72°].

Oxim (C1,H33)2C:NOH. [63°]. White powder, m. sol. hot benzene and alcohol, insol. water and alkalis (Spiegler, B. 17, 1575; Kipping, C. J. 57, 540).

STEAROXYLIC ACID C18H32O4. 312. [86°]. Formed by the oxidation of stearolic acid (Överbeck, A. 140, 63; Hazura a. Grüssner, M. 9, 952). Plates or needles, sl. sol. cold al-cohol. BaA'₂.—AgA': crystalline powder. STEARYL-GLYCERIN v. GLYCERIN.

STEEL v. Iron, vol. iii. p. 53, and Dictionary OF APPLIED CHEMISTRY, vol. ii. p. 360.

STIBINE. Synonym of antimony hydride, v. vol. i. p. 288.

STÎLBENE v. DI-PHENYL-ETHYLENE.

STILBENE ALCOHOL v. HYDROBENZOÏN. STILBENE DIBROMIDE v. DI-BROMO-PHENYI-ETHANE

STILBENE DICARBOXYLIC ACID v. Di-Phenyl-Maleïg Acid.

STILBENE DICHLORIDE v. DI-CHLORO. PHENYL-ETHANE.

STOICHIOMETRY. The laws of chemical combination, and their application to chemical calculations; v. Combination, CHEMICAL, LAWS OF. vol. ii. p. 235.

STORAX. A balsam produced by Styrag officinalis, a shrub growing in the Levant. It occurs in two varieties, liquid storax and reed storax, the latter containing a large quantity of bark. Liquid storax is a brownish-yellow sticky mass containing styrene, styracin, cinnamic acid, phenylpropyl cinnamate, a little ethyl cinnam. ate, a substance [65°] smelling like vanilla (possibly ethyl-vanillin), and (a) and (β)-storesinol (W. von Miller, N. R. P. 24, 1; B. 9, 274; A. 188, 184; 189, 838).

(a)-Storesinol C₃₈H₅₈O₅ i.e. C₃₆H₅₈(OH)₅. [160°-168°]. Amorphous, v. sol. dilute KOHAq.4

but conc. KOHAq ppts. CasH soO.K. Yields a mono and tri-acetyl derivative.

(8)-Storesinol. [140°-145°]. Amorphous. Forms amorphous $C_{36}H_{36}O_4K$, which is more sol.

water than its (a)- isomeride.

STRONTIA. Oxide of strontium (q.v. p. 516).

STRONTIUM. Sr. At. w. 87.3. Mol. w. not known. Very little known about properties. Doubtful if approximately pure Sr has yet been isolated. S.G. c. 2.4 to 2.58 (Franz, J. pr. 107, 253; Matthiessen, J. 8, 324). For emissionspectrum v. B. A. 1884. 444. H.C. [Sr,O] =

128, 440 (Th. 3, 258).

Occurrence. - Compounds of Sr are widely distributed, but not in very large quantities. SrCO, occurs in small quantities in all specimens of arragonite; very small quantities are found in many calc-spars, marbles, and dolomites. SrSO, is an ingredient of many heavy spars. SrCO, is found as strontianite, and SrSO, as celestine in a few localities; brewsterite contains Sr silicate, with silicates of Ba or Ca. Traces of SrSO, and SrCl, are found in many mineral springs, in some hard river-waters, in sea-water, and in the sshes of certain plants, especially Fucus vesiculosus.

Historical.—A mineral found at Strontian, a village in Argyleshire, in 1787, and supposed to be barium carbonate, was observed to colour flame reddish by Crawford and Cruikshank in 1790 (Mem. Manchester Soc.). The supposition made by C. a. C. that the mineral contained a new element was confirmed by Hope (T. E. 4, 3), Klaproth (Crell's Ann. 1793 [ii.] 189; 1794 (i.) 99), and Kirwan-Higgins (Crell's Ann. 1795 (ii.) 119, 205). The metal was isolated by Davy in

1808 (T. 1808. 345).

Formation.-1. By electrolysing moist SrO₂H₂ or SrCl, in contact with Hg and a little naphtha, and heating the amalgam so formed (Davy, T. 1808. 345).-2. By heating saturated SrCl2Aq with Na amalgam to 90°, quickly washing the Sr amalgam so formed, drying it by filter paper, and distilling off the Hg in a stream of H (Franz, J.pr. 107, 253).—3. By heating SrO or SrO,H, intimately mixed with Mg powder, a mixture of Sr with MgO is obtained (Winkler, B. 23, 125,

Preparation .- A porous clay cylinder is placed in a crucible, and SrCl₂, mixed with a little NH₄Cl, is placed in the crucible and in the cell, so that when the mixture is fused the surface of it is at a higher level in the cell than in the crucible. A cylinder of sheet iron surrounding the cell serves as the positive electrode, and an iron wire passing through a tobacco pipe, the bowl of which dips under the molten mixture in the cell, serves as the negative electrode. The crucible is heated till the mixture of SrCl2 and NH4Cl melts, temperature being kept so that there is always a solid crust on the surface of the mixture in the porous cell. A current from 5 or 6 Bunsen cells is passed through the molten mass; Sr is separated and runs into small pieces, which are pro-tected from the air by the solid crust of SrCl. and NH,Cl; the pieces of Sr are removed by an iron spoon and kept under petroleum.

For the preparation of pure Sr salts from strontianite v. Barthe a. Falières (Bl. [3] 7, 104). Properties.—A yellowish white metal, somewhat harder than Ca or Pb; can be beaten into

thin leaves; melts at full red heat. According to Mallet (A. 190, 62), Sr is slightly volatilised at a very high temperature. Easily oxidised by exposure to air; decomposes cold water rapidly; dissolves in dilute acids, not in HNO, Aq, giving salts and H. Combines directly with S and the halogens. Sr is a strongly positive metal, less positive than the alkali metals and Ca, but more positive than Mg; it is closely related to Ca and Ba, less closely to Mg; it also shows resemblances to Zn, Cd, and Hg (v. Alkaline earths, metals OF THE, vol. i. p. 112; and MAGNESIUM GROUP OF OF THE, vol. 1. p. 112; and MAGNESIUM GROUP OF ELEMENTS, vol. iii. p. 163). The atomic weight of Sr has been determined (1) by determining CO₂ in SrCO₂ (Stromeyer, S. 19, 228 [1816]; Salvétat, C. R. 17, 318 [1843]); (2) by ppg. Cl from SrCl₂ by Ag (Rose, S. 19, 228 [1816]; Pelouze, C. R. 20, 1047 [1845]; Marignac, A. 104, 169 [1856]. 106, 168 [1858]; Dumas, A. Ch. [3] 55, 191 [1859]); (3) by determining water in SrCl.,6H₂O (Marignao, A. 106, 168 [1858]); (4) by transforming SrCl.,6H₂O into SrSO, (Marignao, l.c.). The S.H. of Sr has not been determined directly. The V.D. of no compound of Sr has been determined.

Reactions and Combinations (v. Bunsen, A. 94, 111).—1. Exposed to air or oxygen rapidly forms SrO, or SrO2H2 if moisture is present.-2. Burns brilliantly when heated in oxygen, sulphur vapour, chlorine, bromine, or iodine vapour; also in dry carbon dioxide. - 3. Decomposes cold water rapidly, giving off H and forming SrO₂H₂. - 4. Dissolves rapidly in dilute hydrochloric or sulphuric acid; reacts slowly with conc. sulphuric acid; scarcely acted on by nitric acid, even when hot and conc .- 5. Reduces silica and silicates when heated therewith to full redness.

Strontium, antimonate of; v. vol. i. p. 286. Strontium, arsenates of; v. vol. i. p. 309. Strontium, arsenite of; v. vol. i. p. 307. Strontium, borates of; v. vol. i. p. 530.

Strontium, bromide of, SrBr. Mol. w. not determined. By heating St in Br. By dissolving SrCO, in HBrAq and evaporating, long white needles of the hydrate SrBr2. 6aq are obtained (Löwig, Mag. Pharm. 33, 7); S.G. 2·358 (Favre a. Valson, C. R. 77, 579); these crystals do not effloresce over H.SO, (Rammelsberg, P. 55, 238), but on heating give off their water, leaving SrBr2 as a white solid, S.G. 3.985 (F. a. V., l.c.), that melts at red heat without decomposition (R., l.c.). $[Sr,Br^2] = 157,700 \ (Th. 3, 258)$. Carnelley (C. J. 33, 279) gives melting-point as c. 630°. Combines with ammonia to form 2SrBr., NH, (Rammelsberg, P. 55, 238).

Strontium, chloride of, SrCl2. Mol. w. not determined.

Formation.—1. By burning Sr in Cl.—2. By passing Cl over hot SrO (Weber, P. 112, 619). 3. By heating SrO in a stream of HCl (Chevreul, 3. Ch. 84, 285).—4. By decomposing SrCO₂ by conc. CaCl₂Aq or MgCl₂ by heating together, then dissolving out SrCl₂ and crystallising (SrCO₂ + MgCl₂Aq = SrCl₂Aq + MgO + CO₂; Wackenroder's Patent; v. B. 19, Ref. 638).—5. By heating a mixture of SrSO₂, CaCl₂, and characteristics of the state of the s

coal with a little chalk, lixiviating, and crystallising (SrSO, + CaCl, + 4C = SrCl, + CaS + 4CO; Mactear, D. P. J. 262, 288). Preparation.—Strontante (SrOO₂) is dissolved in HOlAq, the solution is digested in absence of air with more SrOO₂ (to remove iron, &c.), poured off and evaporated to the crystallising point; the crystals of SrOI₂ flaq that separate are purified by re-crystallisation, then dried and heated to 100° until they cease to lose weight.

Properties.—A white crystalline powder, with a sharp, bitter taste. Melts at 825° (Carnelley, C. J. 83, 280) to a glass-like mass with an alkaline reaction. S.G. 2.96 at 0°; 2.77 at mp. (Quincke, P. 138, 141). S. 44.2 at 0°, 48.3 at 10°, 53.9 at 20°, 60 at 30°, 66.7 at 40°, 74.4 at 50°, 83.1 at 60°, 87.5 at 65°, 88.8 at 66.5°, 89.6 at 70°, 92.4 at 80°, 96.2 at 90°, 101.9 at 100°, 109.1 at 110°, 116.4 at 118.8°; saturated SrCl_Aq boils at 118.8° (Mulder). Gerlach (Fr. 8, 245) gives the following data:—

B.G. SrCl.Aq	P.o. SrCl. 1	S.G. SrCl.Aq	P.c. SrCl.
1.0453	5	1.2580	25
1.0929	10	1.3220	30
1.1439	15	1.3633	33
1.1989	20		

SrCl₂ is insol. absolute alcohol; it dissolves in aqueous alcohol in proportion to the amount of water present (Gerardin, A. Ch. [4] 5, 156). [Sr,Cl²] = 184,550; [Sr,Cl²,Aq] = 195,690 (Th. 3, 258). For connection between solubility in water of SrCl₂ and temperature v. Etard (C. R. 113, 854).

Reactions and Combinations.—1. Heated to redness in water vapour, HCl is given off and SrO remains (Kraus, P. 43, 138; Kahnheim, J. 1861. 149).—2. Heated with bromine to 200° is partially decomposed to SrBr. (Potilitzin, B. 7, 733; 8, 760); the amount of decomposition varies with temperature and the relative masses of SrCl. and Br.—3. Combines with water. Solution of SrCO, in HClAq evaporated yields long, six-sided, hexagonal needles of the hexahydrate SrCl. 6H.O; S.G. 1-933 at 17°. By keeping these crystals over H.SO, in vacuo for some months the dihydrate SrCl. 2H.O is formed.—4. Combines with ammonia to form SrCl. 2NH (H. Rose, P. 20, 155).

Strontium, cyanide of; v. vol. ii. p. 347.

Strontium, ferrocyanide of; v. vol. ii. p. 337. Strontium, fluoride of, SrF₂. A white, orystalline powder; scarcely sol. water or HFAq. Prepared by the action of HFAq on SrO or SrCO₂ (Berzelius, P. 1, 20); also by fusing 2 parts SrCl₂ with 1 part NaF and 1 part NaCl, and lixiviating the product (Röder, Dissertation [Göttingen, 1863] 14; Feldmann, B. 21, Ref. 866 [Patent]). Poulenc (C. R. 116, 987) obtained SrF₂, as an amorphous powder, by the reaction of HFAq and SrCl₂Aq; S.G. 2·44; partly decomposed to SrO by heating in air to c. 1000°. By fusing with alkali chlorides, or with KHF₂, P. obtained SrF₂ in regular octahedral crystals.

Strontium, hydride of. By heating to redness a mixture of 103 parts SrO (made from SrCO₂) with 24 parts Mg powder, in an iron tube, in an atmosphere of H, Winkler (B. 24, 1975) obtained a greyish-brown powder that quickly oxidised in air to SrO₂H, with evolution of H, and was decomposed very rapidly by water or HClAq with violent evolution of H. Analyses

indicated that the substance might be a mixture of c. 66 p.c. SrH with c. 29 p.c. MgO, c. 4 p.c. SrO, and a very little Mg.

Strontium, hydrosulphide of, SrS₂H₂xH₃O. By saturating SrOAq with H₂S and evaporating in vacuo over H₂SO₄; or by dissolving SrS in water, evaporating, filtering from SrO₂H₂, and evaporating over H₂SO₄ in vacuo. Large, white crystals; melts when heated in water of crystallisation, and then gives SrS. Aqueous solution boiled gives off all H₂S and forms SrO₂H₂ (v. Rose, P. 55, 430; Berzelius, P. 6, 442).

Strontium, hydroxide of, SrO₂H₂. Mol. w. not determined. Prepared by the action of water on SrO. Also by heating celestine (SrSO₄) with charcoal, dissolving SrS so formed in water, heating with CuO or ZnO, filtering from CuS or ZnS, evaporating to dryness, and heating to redness (cf. Banum Hyddoxide, vol. i, p. 442).

A white solid; S.G. 3·625 (Filhol, A. Ch. [3] 21, 415). Sol. water, forming a markedly alkaline solution reacting similarly to BaO.H_Aq and CaO.H_Aq. Scheibler (C. C. [3] 13, 33) gives the following data, showing solubility in water, expressed in terms of SrO, Had the hydrate SrO.H., SH_O, dissolved:—

m	S.		m		8.	
Temp.	SrO	SrO.H.8H.6	Temp.	SrO	SrO.H.8H.O	
0°	•35	·90 ·	55°	2.54	6.52	
5	•41	1.05	60	3.03	7.77	
10	•48	1.23	65	3.62	9.29	
15	•57	1.46	70	4.35	11.16	
20	•68	1.74	75	5.30	13.60	
25	.82	2.10	80	6.56	16.83	
30	1.00	2.57	85	9.00	23.09	
35	1.22	3.13	90	12.00	80·78	
40	1.48	3.80	95	15.15	38·8 6	
45	1.78	4.57	100	18.60	47.71	
50	2.13	5.46	101.2	19.40	49.75	

Dry SrO₂H₂ takes up only traces of CO₂ from the air (Heyer, B. 19, 2684); but the hydrate SrO₄H₂·H₂O absorbs CO₂ till it is changed to SrCO₃ (H., l.c.); according to Finkener (B. 19, 2958) a basic carbonate is formed.

The octohydrate, SrO₂H₂·8H₂O, crystallises in tetragonal crystals (a:c=1:6407) from SrOAq; S.G. 1·396 at 16°; in air falls to powder, giving the monohydrate SrO₂H₂·H₂O, which loses H₂O at 100° (v. Finkener, l.c.; Müller-Erzbach, B. 19, 2874; 20, 1628). Weisberg (B. 11, 511) says that Cl reacts with the hydrates of SrO₂H₂ to give SrCl₂ and Sr(ClO₂).

says that Cr reacts with the hydrates of SrO₂B₂ to give SrCl, and Sr(ClO₂)₂.

Strontium, iodide of, SrI₂. A white solid; by dissolving SrCO₂ in HIAq, evaporating, and heating the hexahydrate, SrI₂.6H₂O₂ which crystallises out. S.G. 4415; melts at red heat; strongly heated in air gives SrO and I (Croft, J. pr. 68, 420). Thomsen gives [Sr,I²,Aq] = 143,460 (Th. 3, 258).

Strontium, manganocyanide of; v. vol. ii. p. 342.

Strontium, nitride of. By heating Sr amalgam containing from 20 to 25 p.c. Sr (prepared by electrolysis and heating the product in accuo) in a stream of N, Maquenne (Bl. [8] 7, 366) obtained a dark-coloured compound of Sr and N to which he gave the formula Sr₂N₂.

Strontium, oxides of. Two oxides have been isolated, SrO and SrO₃.

STEONTIUM OXIDE STO. (Strontium monocide. Strontia.) Mol. w. not known. Prepared by strongly heating SrO₂H₂, Sr(NO₃)₂, SrOO₂ (Brügelmann, Fr. 29, 127; Heyer, B. 19, 2684); also by strongly heating SrI₂in air (Croft, J. pr. 68, 420). Best prepared similarly to BaO (v. BARIUM MONOXIDE, vol. i. p. 443). A grey-white, porous, infusible solid; prepared by heating SrCO, or SrO, H, forms a mass of regular cubes with S.G. 4.75 referred to water at 4° (Brügelmann, l.c.). According to Moissan (C. R. 115, 1034), SrO melts to a transparent liquid at c. 30006 and this solidifies to a crystalline mass. Thomsen gives [Sr, O] = 128,440 (Th. 3, 258). Dissolves in water (for data v. Strontium hydroxide); from this solution the octohydrated hydroxide SrO,H,,8H,O separates on evaporation. By passing moist air over SrO the monohydrated hydroxide, SrO2H2.H2O, is formed (Heyer, B. 19, 2684). SrO is a strongly basic oxide, reacting with acids to form salts SrX, where X = SO. 2NO₃, ²PO₄, &c.

STRONTIUM DIOXIDE SrO₂. (Strontium per-oxide.) Mol. w. not known. Addition of H.O.Aq to SrOAq ppts. the octohydrate SrO. SH.O (Thénard, A. Ch. [2] 8, 312; Schöne, B. 6, 1172; cf. Conroy, C. J. [2] 11, 812). By drying this pp. at 100° SrO. is obtained as a white powder, having similar properties to those of barium dioxide (q.v. vol. i. p. 443). SrO, is not obtained by methods similar to those generally used

for making BaO2.

Strontium, oxychloride of. According to André (A. Ch. [6] 3, 66) crystals of the compound SrCl. SrO.9H.O(=Sr.OCl. 9H.O) are deposited from a mixture of saturated SrCl2Aq and saturated SrOAq; the crystals are very unstable in air.

Strontium, oxysulphide of. Schöne (P. 117, 59) obtained SrS. SrO. 12aq(Sr.OS. 12aq) by slow oxidation of SrS,Aq.

Strontium, platinocyanide of; v. vol. ii. p.

Strontium, salts of. Compounds obtained by replacing H of acids by strontium. These compounds belong to the type SrX, where X is SO,, CO,, 2NO,, 3PO, &c. The Sr salts are very definite compounds; not many basic salts are known. The chief salts of oxyacids are the following: bromate and hypobromite, carbonate, chlorate, chlorite and perchlorate, chromate and dichromate, iodate and periodates, molybdate, nitrate, nitrite, and hyponitrite, selenate and selenites, sulphate, sulphite, thibsulphate, and thionates (v. Carbonates, nitrates, &c.).

Strontium, selenide of. Obtained as a white solid, rapidly decomposing in air with separation of Se, by heating a small quantity of SrSeO, in H to dull redness; [Sr,Se] = 87,160 (Fabre, C. R.

102, 1469)

Strontium, silicofluoride of, SrSiF.2H.O. Four-sided prisms; S.G. 2.999; loses 2H₂O when gently warmed; prepared by dissolving SrCO, in H₂SiF₆Aq and evaporating (Berzelius, Lehrbuch [5th edit.], 3, 385]. Fresenius (Fr. 29, 143) gives S. 3·2 at 15°; S. in alcohol (50 p.c. by vol.) ·06 at 15°.

Strontium, sulphides of. Three sulphides have been isolated : SrS, SrS,, and SrS,.

STRONTIUM MONOSULPHIDE SrS. Formed by cheating together Sr and S in the ratio 87:32;

also by reducing SrSO, by charcoal; also by passing CS, vapour mixed with H. H.S. or CO. over red-hot SrCO₃ (cf. Barium monosulphide, vol. i. p. 444). A white powder, which slowly becomes yellowish when exposed to air. Does not phosphoresce (Schöne, P. 117, 59). For phosphorescence of SrS mixed with small quantities of other salts v. Becquerel (C. R. 107, 892). Sabatier (A. Ch. [5] 22, 5) gives [Sr,S] = 49,600. SrS does not combine with S when heated therewith, but polysulphides are formed by boiling an aqueous solution of SrS with S (Schöne, P. 117, 59). SrS dissolves in water; on crystallising SrO₂H₂ separates and SrS₂H₂ remains in solution (H. Rose, P. 55, 430).

STRONTIUM TETRASULPHIDE STS .. xH,O. The hexahydrate, SrS, 6H2O, is obtained, as a reddish crystalline solid, by boiling 100 parts SrS in water, and evaporating the solution in vacuo at a temperature not higher than 16°. From a solution at 20°-25° the dihydrate SrS, 2H,O separates. An aqueous solution of SrS, oxidises in air to the oxysulphide SrO.SrS, 12aq, and then to SrS₂O₃, while S separates and some SrCO₃

is formed (Schöne, P. 117, 59).

STRONTIUM PENTASULPHIDE SrS, xH20. amorphous, yellowish, hygroscopic solid; formed by evaporating a solution of SrS, saturated with S in the cold. After drying at 100°, CS, dissolves out the S, leaving SrS, (Schöne,

l.c.). Strontium, sulphydrate of; v. Strontium HYDROSULPHIDE, p. 515.

Strontium, sulphocyanide of; v. vol. ii. p. M. M. P. M.

STROPHANTHIN C₃₁H₄₈O₁₂ (A.); C₂₀H₃₄O₁ (F.). $[\alpha]_D = 30^\circ$. Extracted by alcohol at 70° from the seeds of Strophanthus hispidus (Gallois, C. R. 84, 261; Fraser, Ar. Ph. [3] 3, 229; Pr. E. 124, 370; Ph. [3] 18, 69; Elborne, Ph. [3] 17, 743; 18, 219; Gerrard, Ph. [3] 17, 923; Arnaud, C. R. 107, 179; Gley, C. R. 107, 348). White micaceous crystals, sol. water, v. sol. alcohol, insol. ether. Dextrorotatory. Bitter. Resembles ouabain in toxic effects. Decomposed by boiling dilute acids (even H2S) into glucose and crystalline strophanthidin, which yields a resin on further boiling with dilute H, SO, (F.). H2SO, and a trace of FeCl, gives a reddishbrown pp., changing to emerald-green (Helbing, Ph. [3] 17, 924).

STRUTHIIN v. SAPONIN. STRYCHNIC ACID C20H22NO(NH).CO2H. Formed from strychnine, alcohol, and Na at 50°-55° (Tafel, A. 264, 50). When heated in a current of H at 190° it changes to strychnine. K2Cr2O, and H2SO, give a brown-red colour or pp.

Nitrosamine C20H22NO(N.NO).CO2H. Gelatinous pp. Exhibits Liebermann's reaction.

Methylo-iodide C₂₀H₂₂N(MeI)O(NH).CO₂H. Formed methyl-strychnine and HI (Tafel, A. 264, 55). Colourless needles (containing aq), v. sl. sol. cold alcohol and cold water.—NaA' aq: v.e. sol. water, m. sol. alcohol. Converted by MeI into crystalline C20H22N(MeI)(NMe).CO2Me.

Methyl-strychnic acid. Methylo-iodide. C₂₀H₂₂N(MeI)O(NMe).CO₂H. Formed from dimethyl-strychnine and HI (Tafel, A. 264, 58). Needles, m. sol. boiling water and hot alcohol.

Decxystrychnic acid C,H2eN(NH).CO2H aq. formed by heating deoxystrychnine with alcoholic NaOEt at 180° (Tafel, A. 268, 253). Needles (containing aq) (from dilute H,SO,) or anhydrous prisms (from alcohol), sl. sol. hot water. Quickly converted by acids into deoxystrychnine. Yields a nitrosamine.

Isostrychnic acid C20H2NO(NH).CO2H. Formed from strychnine, Na, and alcohol at 70°. Got also by heating strychnine with baryta-water at 140° in absence of air. Minute needles. K₂Cr₂O₇ and dilute H₂SO₄ form a brown liquid on heating, and a brown pp. with excess of K₂Cr₂O₇.—HA'HI aq: prisms, m. sol.

cold water and alcohol, insol. ether.

Nitroso-derivative NO.C₂₀H₂₁NO(NH).CO₂H aq. Sol. alkalis, but ppd. by CO₂. Yields a nitrosamine, which gives Liebermann's reaction with phenol and H2SO4. --HA'HCl: needles, insol. water.

Methylo-iodide

C20H22N(MeI)O(NH).CO2H. Crystalline, m. sol. hot water .- NaA': minute needles. Converted by methyl iodide at 100° into crystalline C₂₀H₂₂N(MeI)O(NMc).CO₂Me 2aq.

Methyl-isostrychnic acid

C20H22NO(NMe).CO2H. From isostrychnic acid hydroiodide and McI at 100° (Tafel, A. 268, 240). Small colourless prisms (containing 2 aq). Its alkaline solution is not coloured by air (difference from isostrychnic acid).

Methylo-iodide

C.H., N(MeI)O(NMe).CO.H aq [271°-275°]. Formed from methyl-strychnine methylo-iodide and HI (Tafel, A. 264, 77). Needles, m. sol. hot water and hot alcohol, insol. ether.

Nitroso-methyl-isostrychnic acid

NO.C₂₀H₂₁ON(NMe).CO₂H. Formed from the preceding acid, alcohol, HCl, and amyl nitrite. Green needles (from benzene). When heated with benzoic aldehyde and ZnCl₂ it gives a green mass, which dyes like malachite green. Diazo-benzene chloride forms a brownish-orange dye.

STRYCHNINE C_{.1}H_{.2}N_{.2}O_{..} Mol. w. 33a. [221°] (Blyth); [284°] (Claus a. Glassner, B. 14, 773); [268°] (Logbisch a. Schoop, M. 6, 858); [269°] (Stochr). (270° at 5 mm.). S.G. ½ 1.359 (Clarke, 4m. 2, 174). S. 015 in the cold; 04 at 100°. S. 014 in the cold (Dragendorff, J. 1865, 739); 025 at 14.5° (Crespi, G. 13, 175). S. (alcohol) 3 at 8°; 1.8 at 78°. S. (95 p.c. alcohol) 936. S. (ether) 08. S. (benzene) 607. S. (isoamyl alcohol) 53 at 12°; 4.3 at 99°. Occurs in nux vomica, in St. Ignatius beans, in the wood of Strychnos Colubrina, in Strychnos Tieuté, and in other species of Strychnos (Pelletier a. Caventou, A. Ch. [2] 10, 142; 26, 44; Pelletier a. Dumas, A. Ch. [2] 24, 176; Liebig, A. 47, 171; 49, 244; Regnault, A. Ch. [2] 68, 113; Gerhardt, Rev. Scient. 10, 192; Nicholson a. Abel, C. J. 2, 241; Henry, Ph. 8, 401; Corriol,
Ph. 11, 492; Robiquet, Ph. 11, 580; Henry,
jun., J. Ph. 16, 752; Berlekom, Z. [2] 2, 443; Shenstone, Ph. [3] 8, 445). Occurs also in the bark of Erythrophlaum guineense, from which the pigmies of Central Africa prepare their arrow-poison (Holmes, Ph. [3] 21, 921).

Preparation .- 1. The nuts (1 kilo) are softened by steam, dried, powdered, and digested with alcohol (5 kilos of S.G. 856) acidulated with

H.SO, (45 g.). Lime is added to the filtrate; and, after standing, the decanted liquid evaporated; the residue dissolved in dilute soid; and the filtrate ppd. by ammonia. The strychnine is separated from brucine by crystallisation from alcohol (Henry) .- 2. The dilute alcoholic extract of nux vomica is evaporated to a small bulk and ppd. by lead acetate. The filtrate is mixed with magnesia and left for a few days. The pp. is dissolved in alcohol of 83 p.c. and evaporated to crystallisation. Strychnine is first deposited, and afterwards brucine. The bases are further purified by crystallisation of their nitrates, the nitrate of strychning separating first.

Properties.-Trimetric prisms, permanent in the air and not altered by light. Lævorotatory, the rotation varying greatly with the nature of the solvent (Hoorweg, A. 166, 76; Tykociner, R. T. C. 1, 146). The dispersive power is constant (Grimbert, J. Ph. [5] 16, 295). At 169° it forms a sublimate of minute needles (Blyth). Very bitter. Alkaline in reaction. Strychnine is a violent poison, acting on the spinal cord and producing convulsions (Lovett, J. Physiol. 9, 99). 03 g. may be fatal. Strychnine dissolves with difficulty in acids, the solubility being greater the more dilute the acid; when a conc. solution of a strychnine salt is slightly acidified a pp. is formed which dissolves in excess of acid, forming a solution which yields a pp. on dilution. Thus H.SO, added to a conc. solution of strychnine sulphate ppts. the acid sulphate B'H₂SO₄, the mother-liquor retaining 113 p.c. of salts. HCl added to a solution of strychnine hydrochloride ppts. B'HCllag in needles, the mother-liquor retaining 413 p.c. of salt (Han-riot a. Blarez, C. R. 96, 1504). Strychnine is readily soluble in dilute hypophosphorous acid (Jones, Ph. [3] 20, 256). KCy added to a solution of a salt of strychnine ppts. the pure base (Flückiger, N. J. P. 38, 138; Weith, B. 4. 527). A solution of ICl gives a yellow pp. v. sol. HCÍAq, from which it crystallises on cooling (Dittmar, B. 18, 1612).

Reactions.—1. Dry distillation yields carbazole, H, C, H, and C, H, (Loebisch a. Schoop, M. 7, 614). - 2. Distillation with lime yields (3)-methylpyridine, methyl-indole (scatole), C2H4, NEtH2, and NH₃ (Stochr, B. 20, 810, 1108, 2729; J. pr. [2] 42, 405).—3. Distillation with soda-lims gives carbazole, scatole, and (8)-methyl-pyridine (Loebisch a. Malfatti, M. 9, 628).—4. Distillation with KOH gives indole (Goldschmidt, B. 15, 1977) and batyric acid (Loebisch a. Schoop, M. 7, 93) .- 5. Distillation with zinc-dust at 400° in vacuo yields solid C₂;H_{2;N.O}, which dissolves in alcohol with blue fluorescence, and gives no colour with K₂Cr₂O, and H₂SO₄. Zinc-dust at a red heat gives H, C₂H₁, C₂H₂, NH₃, and carbazole (Loebisch a, Schoop, M. 7, 609), and (γ)-lutidine (Scichilone a. Magnanini, G. 12, 444).— 6. Alkaline KMnO, yields oxalic acid, CO, NH,, and a crystalline acid [195°] (Hoogewerff a. Van Dorp, R. T. C. 2, 181). Half the nitrogen is given off as ammonia (Wanklyn a. Chapman, C. J. 21, 161).-7. KMnO, in dilute acid solutions yields an amorphous acid C₁H₁₁NO₂ aq (?) (Plugge, R. T. C. 2, 270), which yields amorphous C₁₁H₁₆AgNO₂ aq (Hanriot, C. R. 96, 1671).—8. By treatment with CrO₂ and H₂SO₄ it yields the same oxidation product C, H, N,O, as that ob-

tained from brucine under the same treatment (Hanssen, B. 18, 1917).—9. PCl, (1 pt.) acting on strychnine hydrochloride (8 pts.) under boiling chloroform yields a compound crystallising from benzene in needles [224°], possibly penta-chlorostrychnine (Stoehr, J. pr. [2] 42, 414).—10. Boiling HNO, forms cacostrychnine and picric acid (Shenstone, C. J. 47, 142); nitric acid forms 20 p.c. of di-nitro-di-oxy-quinoline carboxylic acid C₁₀H₄N₂O₂, which yields KA', is reduced by SnCl₂ to C₁₀H₂N₂O₄ (a body having acid and basic properties), and when heated with water is split up into CO, and di-nitro-di-oxy-quinol-ine (Tafel, B. 26, 353).—11. Baryta water in sealed tubes at 140° forms two bases, C2, H2, N2O4 and C_{s.}H₂₈N₂O₅, both crystallising from water (Gal a. Etard, C. R. 87, 362).—12. Alloxan added to a solution of strychnine in a saturated solution of SO, forms small colourless prisms of B'C,H,N,O,H,SO, aq (Pellizzari, A. 248, 150).— 18. Iodoform (5 g.) and strychnine (12 g.) dissolved in hot alcohol (500 c.c.) deposit on cooling crystals of B', CHI,, sol. ether and chloroform, but decomposed by light, hot water, and dilute acids (Lextrcit, C. R. 92, 1057).—
14. Chloro-acetic acid at 180° forms C₁₃H₂₁N₂O₄, a base which crystallises in silky needles, v. sol. hot water and alcohol, insol. ether (Roemer, Z. 1871, 435). It yields $(C_{33}H_{21}N_{2}O)_{3}PtCl_{3}$.

15. AcCl forms B'AcCl, which gives (B'AcCl)_PtCl_{4}(Konrad, J. 1874, 876).—16. Chloro-acctone at 185° yields B'O,H,ClO, S. 6·5 at 15°, which yields B'O,H (B'C,H,ClO),PtCl, 2aq and B'C,H,OSO,H 1 aq (Konrad).—17. Aqueous SO₂ and alloxan give colourless prisms of B'SO₂HC₄H₂N₂O₄ aq (Pelliz-

Eari, G. 18, 329).

Detection.—1. H,SO, forms a colourless solution which with K.Cr₂O, gives a blue colour, changing through violet and red to yellow (Otto, A. 60, 273). A drop of nitric acid and PbO, or MnO, may be used instead of K,Cr₂O, (Marchand, B. J. 24, 400; Davy, A. 88, 402). KMnO₄ and Ag₅O act in like manner (Lyman, Fr. 12, 126). The colour with H2SO4 and K2Cr2O2 is not shown in presence of brucine (Hanriot, C. R. 97, 267), and is interfered with by quinine, morphine, and sugar (Brieger, J. 1850, 617; Vogel, J. 1853, 686; Flückiger, Fr. 28, 102).—2. A minute quantity of KClO, added to a warm solution in dilute HNO, gives a scarlet colour, changed by ammonia to brown, and then, on evaporation to dryness, becoming green (C. L. Bloxam, C. N. 55, 155).-3. Ammonium vanadate in H2SO4 gives a blue colour, turned red by potash (Mandelin, Fr. 23, 240).—4. Chlorine water gives a pp.-5. Strychnine can be extracted from beer containing the poison by shaking with animal charcoal, the charcoal being subsequently extracted with alcohol (Graham a. Hofmann, A. 83, 39; cf. Wagner, Fr. 6, 387).—6. Obtained from acid liquids by adding ammonia and immediately shaking with chloroform (Cloetta, Fr. 5, 265; Gray, Fr. 12, 125). -7. A liquid containing strychnine sulphate may be shaken with benzene without loss of strychnine, but if the liquid be neutralised by magnesia the free strychnine can be extracted by benzene (Dragendorff, Z. [2] 2, 27).-8. A 1 p.c. solution of strychnine strongly acidified by HCl is ppd. by K, FeCy, while brucine remains in solution (Holst A. Beckürts). This may be used as a volumetric method. Strychnine and brucine may also be

method: Stryonnine and brucine may also se separated by crystallisation of their picrates (Gerock, Ar. Ph. [8] 27, 158).

Salts.—B'HOlligaq (Regnault, A. 26, 17).

Trimetric crystals; a:b:c:= 484:1:466 (Stoehr, J. pr. [2] 42, 399). Neutral in reaction. S. 2

at 22°. Levorotatory. [a]_r = -28°.—B'HAuCl.

Orange crystals (from alcohol) (Nicholson a. Abel, C. 7, 2, 24; 4, 71, 24). Decomposed by boiling C. J. 2, 241; A. 71, 84). Decomposed by boiling water (O. De Coninck, Bl. [2] 45, 131).—B'₂H₂PtCl₆: golden scales (from alcohol). S.G. 18.5 1.779 (Clarke, Am. 2, 175).—B'₂H₂PtCl₃ aq (Schmidt, A. 180, 295).—B'₂H₂ZnCl₄ aq: prisms (Grafinghoff, Bl. [2] 4, 391).—B'₂H₂CdCl₄ (Galletly, N. ed. P. J. 4, 94).—B'HHgCl₃. Crystals (from the content of alcohol).—B'HgCl₂: insol. alcohol, water, and ether.—B'₂H₂SQ₂HgCl₂.—B'₂H₂PdCl₄: dark-brown needles (from alcohol).—B'HCl2HgOy₂: tables (Brandis, A. 66, 268).—B'HgCy2: small prisms, sl. sol. water and alcohol, insol. ether. -B'HBraq: needles, sol. water and alcohol.-B'HI aq: plates or needles, almost insol. cold water.—B'HI,. S. 007 at 15°. Reddish-brown pp. got by adding a solution of I in HIAq to a salt of strychnine. Crystallises from alcohol in dark-brown needles with bluish metallic lustre. Dichroic (brown and yellow) in polarised light. M. sol. hot alcohol, sl. sol. chloroform, nearly M. Sol. Hot sicond, St. Sol. chloroform, nearly insol. C9, (Tilden, C. J. 18, 99; Herapath, Pr. 8, 149; Bauer, Ar. Ph. [3] 5, 289; Jörgensen, A. Ch. [4] 9, 116).—B'HHgI,: yellow tables (from alcohol) (Groves, C. J. 2, 97).—B'H, F. 2aq: prisms (Elderhorst, A. 74, 77).—B'HNO; needles.—B'HClO, aq: prisms, sl. sol. cold water (Boedeker, A. 71, 62).—B'H, SO, 2aq: needles.—B'HSO. Four, sided prigns. Level needles.—B'₁H₂SO₄. Four-sided prisms. Levorotatory [a]₁ = -26° .—B'₂H₂SO₄ 5aq: long thin prisms. Got by crystallisation between 109° and prisans. Got by erystatination between 109° and 95°.—B'₂H₂SO₄6aq. Obtained by cooling a conc. solution to 95°-50° (Lextreit, J. Ph. [5] 6, 259; Rammelsberg, B. 14, 1231; cf. Baumhauer, C. J. 44, 485).—B'₂H₂CrO₄; lemon-yellow needles, sl. sol. water and alcohol. -B'2H2S2O348q. S. I in the cold. Formed by atmospheric oxidation of a mixture of strychnine, alcohol, and ammonium sulphide (How, G. N. 18, 232).—
B'₂H₂S₀. Formed from strychnine and alcoholic ammonium polysulphide (Hofmann, B. 1, 81; 10, 1087) and by atmospheric oxidation of a solution of strychnine in clooholic H2S (Schmidt. B. 5, 1267; 10, 1288; A. 180, 288). Orange needles, insol. water, alcohol, and ether.—
B'H,PO, 2aq. S. 19. Needles (Anderson, A. 66, 56).—B',H,PO, 9aq: rectangular tables.—
B'H,AsO, 9aq. S. 7 in the cold; 20 in hot water.
—B'HAsO, efflorescent cubes. S. 3 in the cold; 10 at 100°.—B' H. FaCt. Asa. Caratellian powels. 10 at 100°.—B',H,FeCy, 4aq. Crystalline powder (Holst a. Beckurts, Ar. Ph. [3] 25, 318; cf. Brandis, A. 66, 257). By atmospheric oxidation in presence of water it is converted into strychnine and the ferricyanide (Beckürts, B. strychnine and the ferricyanide (Beckürts, B. 18, 1235).—B'H₄FeCy₄: white powder, sol. hot water. Acid in reaction.—B'₂H₃FeCy₆ (aq. golden prisms.—B'₄(H₄CoCy₆) 4aq.—B'₄(H₂NiCy₄) 8aq (Lee, B. 4, 789).—B'₂H₂PtCy₄ 2aq: needles (from alcohol).—O xalate B'₂H₄C₄O₄: flat needles.—B'₂H₄C₄O₄.—B'H₅Cy₆O₄.—B'H₅Cy₇O₇.—B'H₅Cy₇O₇.—B'H₅Cy₇O₇.—B'H₅Cy₇O₇.—B'H₅Cy₇O₇.—B'H₅Cy₇O₇.—B'H₅Cy₇O₇.—B'H₅Cy₇O₇. Red pp., v. sl. sol. hot water (Christensen, J. pr. [3] 45, 367).—B'₂2H₂Pt(SCy)₈. Red crystals (Clarke

and Owens, Am. 3, 851).— Gyanurates: B'₂H₂O₂C₄N, aq. [287°]. Prisms, al. sol. water, m. sol. alcohol.—B'H₂O₄C₅N, aq. [295°]. Needles (Claus, J. pr. [2] 88, 228).—Nitroprusside. S. 12 (Davy, Ph. [3] 11, 756). Succinate B'₂C₄H₄O₄6\(\frac{1}{2}\)aq. (Crespi, G. 13, 176).—Tartates: B'₂C₄H₄O₄.—B'₂O₄H₄O₄. 4aq; white afflorescent needles (Arnna. J. pr. 52, 221). efflorescent needles (Arppe, J. pr. 53, 331).—
B',O,H₂O₆ aq (Pasteur, A. Ch. [3] 38, 437).—
B'O,H₆O₆ 3aq.—B'C,H₅(SbO)O₆. Needles (Stenhouse, A. 129, 25).—Malate B'₂C,H₆O₅ 3\frac{1}{2}aq.—
Pyrotartrate B'₂C,H₆O₅ 3\frac{1}{2}aq.—
Mucate $B'_{2}C_{n}H_{10}O_{n}$. Long needles (Ruhemann a. Dufton, $C.\ J.\ 59,\ 754$).

Di-hydrate B'2aq. Strychnol. Formed by warming strychnine with alcoholic NaOEt, adding water, and evaporating. The brown oily layer that forms is allowed to solidify, dissolved in water, and ppd. by CO₂. The pp. is dissolved in NH₃Aq and re-ppd. by expelling NH₃ by air (Loebisch a. Schoop, M. 7, 83). The same body is got by heating strychnine (15 g.) with BaO2H2 (30 g.) for 12 hours at 140° (Tafel, B. 23, 2737). Minute wedge-shaped needles, sl. sol. cold water, insol. alcohol and ether. Darkens at 150°. Sol. dilute alcohol and solutions of ammonium salts; sol. acids. Converted into strychnine on warming with dilute acids. Dilute HNO, and a little NaNO, give a crimson colour. Bromine water gives a pale-purple colour. Does not give the strychnine reaction with H2SO4 and K2Cr2O7. On heating at 100° with NaOMe and MeI it is converted into C21H22N2O2Me5I 2aq, crystallising in needles.

Tri-hydrate v. Reaction 10. Pentahydrate B'5aq. [215 [215°]. Got by heating strychnine with alcoholic NaOEt (Tafel). Needles, more soluble than the dihydrate. Becomes very hygroscopic when dried in vacuo.

Benzoyl derivative C21H21BzN2O2. V. sl. sol. water (Schützenberger, A. 108, 353; C. R.

47, 233).

Methylo-iodide B'MeI. S. 5 in the cold (Stahlschmidt, P. 108, 513). Poisonous (Crum Brown a. Fraser, Tr. E. 25). Formed by heating with MeI in sealed tubes. Pearly plates. Yields B'MeI₃ (Jörgensen, J. pr. [2] 3, 157) and the salts B'MeBr, B'MeCl 2aq, B',Me,PtCl₃, B'MeAuCl,, B',Me,SO,5aq, B'McHSO. B'MeH, PO, 2aq, B'MeCl2 HgCl2, B'MeNO, and B'2Me2FeCy4.

Methylo-hydroxide B'MeOH or $C_{20}H_{22}O(NH) \gtrless_{CO}^{NMe}>0$. Formed from B'MeI by successive treatment with Ag.SO, and baryta (Tafel, B. 23, 2733; A. 264, 62). Colourless crystals (containing 4aq), v. sol. alcohol, but a product containing less water soon separates. Poisonous. Gives the same colour-reactions as strychnic acid. Alcohol and Na yield a compound [158°]. MeI forms B'MeIMeOH crystal-

lising in plates, decomposed at 280°. Isomeride of the methylo-hydroxide H₂₈N₂O₃7aq. Formed from the methylo-C₂₂H₂₈N₂O₂ 7aq. iodide of isostrychnic acid, Ag, and Ag,O at 40° (Tafel, M. 264, 81). Colourless needles; v. s. sol. hot water and alcohol, insol. ether.

Methyl-strychnine methylo-hydrox. ide $C_{11}H_{22}N_2O_3$ i.e. $C_{20}H_{22}O(NMe) \ll \frac{NMe}{CO} > 0$. Formed from B'MeIMeOH by successive treat-

ment with Ag.SO, and baryta. Got also by the action of Ag.O on the methylo-iodide of methyl. strychnic acid (Tafel, B. 23, 2785; A. 264, 66). Prisms (containing 6aq), v. sol. hot water and alcohol, nearly insol. ether. Gives a blood-red colour with HNO₃, CrO₃, or FeCl₃. Forms with acids salts which differ from those prepared by the action of silver salts on B'MeIMeOH. Forms a crystalline nitroso-derivative, v. sol. water and warm alcohol, forming a yellow solution changed by NaOH to brownish-red and olive-green. HI yields the methylo-iodide of methyl-strychnic acid. Diazobenzene sulphonic acid gives a brownish-red dye .- Hydroiodide. S. 7. Plates. — Methyloiodide C₂₄H₂₁N₂IO₃.
 S. 1. Needles.

Isomeride of methyl-strychnine methylo-hydroxide C2142,N2O, 3aq. Formed from the methylo-hydroxide of methyl-isomethyl-iso-Isomeride of strychnic ether (Tatel, A. 264, 82). Crystals, v. sol. hot water and alcohol, insol. ether. Yields a dye with diazo-benzene sulphonic acid.

Ethylo-iodide B'Etl. S. 6 at 15°; 2 at 100°. Formed by heating strychnine with alcohol and EtI at 100° (How, A. 92, 338). Foursided prisms. Not attacked by KOHAq. Gives the strychnine reaction with K2Cr2O, and H2SO. Converted by moist silver oxide into the base B'EtOH 2aq, which yields the salts B'EtNO,, B'Et_PtCl_s, B'EtHCO,, B'EtHCrO, aq, B'EtCy [105°] (Claus a. Merck, B. 16, 2748), and B'EtI. (Jörgensen, A. Ch. [4] 11, 115).

Isoamylo-chloride B'CsH11Cl jaq. Formed by heating strychnine with isoamyl reinloride (How, Tr. E. 21, 1, 27). Prisms. Yields B'O₂H₁₁OH, B'C₃H₁₁I₃, B'O₃H₁₁I₃, crystallising in black prisms (Jörgensen, J. pr. [2] 8, 145), and B'EtHCrO..

Bromo-ethylo-bromide B'C,H,Br. Formed by heating strychnine with ethylene bromide and alcohol (Ménétriès, J. pr. 85, 230). White crystals, sl. sol. cold water and alcohol. Converted by AgNO, into B'C.H.Br.NO, and by Ag.SO, into B'C,H,Br.SO,H, whence baryta produces alkaline B'C,H,Br.OH. - (B'C,H,Br),PtCl, -B'C_H,BrI3: shining brown laming. -Moist Ag₂O converts B'C₂H₄Br₂ into B'C₂H₄OH, which is alkaline and is converted in aqueous solution by chlorine into C23H21Cl3N2O2.-B'C2H2CrO4H. -(B'C,H,Cl),PtCl,

Chloro-ethylo-hydroxide B'ClC,H,OH. Got by heating strychnine with glycolic chlorhydrin at 150° (Messel, A. 157, 7). Silky needles (containing aq). Yields (B'C₂H₄OH)₂SO₄2aq, which is converted by baryta into crystalline

which is converted by baryta into drystaline (B'C,H,OH)OH2 aq.—(B'C,H,OH)_PtCl₀.

Bensylo-chlorideB'C,H,Cl. [263°]. Prisms (containing aq). Yields (B'C,H,Cl)_PtCl₄ [216°], B'C,H,NO₃ [c. 264°], (B'C,H,),Cr₂O, and B'C,H,SCy [237°] (Garzarolli, M. 10, 1).

Bensylo-hydroxide B'C,H,OH. Plates. Chlorostrychnine $C_{:1}H_{:1}C!N_{:2}O_{::}[a]_{D} = -105^{\circ}$. Formed, together with diand tri-chlorostrychnine, by passing Cl into a solution of strychnine hydrochloride (Laurent, A. Ch. [3] 24, 312; A. 69, 14; Richet a. Bouchardat. C. R. 91, 990). Crystalline, v. sol. alcohol, ether, and chloroform. Chlorostrychnine forms a hydrate C₂₁H₂₁ClN₂O₂ Saq on heating with alcoholis potash. - B', H, SO, 7aq.

Dichloro-strychnine $C_{21}H_{20}Cl_2N_2O_2$. Needles (from alcohol).

(a) Tri-chloro-strychnine C₁₁H₁₂Ol₁N₂O₂. Formed by saturating a solution of strychnine hydrochloride with Ol. Minute crystals (from alcohol). Yields a trihydrate which is not very poisonous.

(β)-Tri-chloro-strychnine C₂₁H₁₉Cl₁N₂O₂.

Formed by heating strychnine hydrochloride with PCl₂ and chloroform (Stochr, J. pr. [2] 42, 412; B. 20, 813). Microcrystalline powder (from alcohol). Gives the strychnine reaction with K₂Cr₂O, and H₂SO, —B'HCl: plates (from dilute alcohol).—B'H₂SO, —B'HCl: plates (from dilute alcohol).—B'H₂SO, Plates, m. sol. water.

Brome-strychnine C₂₁H₂₁BrN₂O₂. [222°].

Formed by adding Br (2 at.) to a solution of

Brome-strychnine \$\overline{O}_{21}\Hat{H}_{21}\Br\N_2\O_2\$. [222°].

Formed by adding Br (2 st.) to a solution of strychnine hydrochloride (1 mol.), ppg. by alkali, and recrystallising from alcohol (Shenstone, C. J. 47, 139; Beckürts, B. 18, 1236; Loebisch a. Schoop, M. 6, 855). Trimetric crystals; abc=1.459:1:1:195 (Miers, C. J. 47, 144).—B'HCl.—B'HBr.—B'HNO,.—B'2\H2\SO,7aq.

Methylo-iodide B'MeI. Pearly plates,

Methylo-iodide B'MeI. Pearly plates, sol. alcohol. Converted by moist Ag₂O into B'MeOH4ag.

B'MeOH4aq.
Dibromide C₂₁H₂₁Br₃N₂O₂. Got by adding Br to a solution of strychnine at 40°. Bright yellow crystalline powder.

Di-brome-strychnine C₂₁H₂₁Br₂N₂O₂. Got by adding Br to strychnine in chloroform. Trimetric crystals, v. sol. chloroform and dilute alcohol.—B'HCl: needles.

Nitro-strychnine C₂₁H₂₁(NO₂)N₂O₂. [225°]. Formed by adding strychnine nitrate to H₂SO₄ (Loebisch a. Schoop, M. 6, 845; 7, 59). Golden plates (from alcohol). Gives no colour with H₂SO₄ and K₂Cr₂O₇. Dissolves in acids and alkalis. On heating with alcoholic potash it is converted into xanthostrychnol C₂₁H₂₁N₃O₄, which forms ruby-red crystals (containing 2aq) and gives salts with acids and bases.—B'HCl.—B'2H₂PtCl₈.—B'2KOH: red deliquescent needles.—B'2H₂O₂H₂2aq.—Ag₂O₂₁H₁₀N₃O₄: unstable pp.

[a] Di-nitro-strychnine C₂₁H₂₀(NO₂)₂N₂O₂.

(a)-Di-nitro-stryohnine C₂₁H₂₆(NO₂)₂N₂O₂.

[226°]. Formed by passing nitrous acid gas into an alcoholic solution of strychnine nitrate (Claus a. Glassner, B. 14, 774). Orange-yellow plates. Converted by dilute HNO₃ into cacostrychnine.—B'HNO₄: yellow nodules (from

acetone), v. sl. sol. hot water.
(8)-Di-nitro-strychnine. Formed by dis solving strychnine (60 g.) in fuming HNO₃ (300 g.) at -10° (Hanriot, C. R. 96, 585). Transparent amber-yellow prisms (from chloroform-alcohol), sol. hot water and alcohol, v. sol. chloroform. Decomposes at about 202°.—B'HCl.—Nitrate: plates (from hot water).

Amido-strychnine v. vol. i. p. 184. Di-amido-strychnine, ibid. Cacostrychnine v. vol. i. p. 654.

 Its salts are more soluble than those of strychnine.—B'HI aq. Groups of prisms.—B'₂H₂Or₂O₃.

Thin yellow needles.—B'₂H₂PtCl₄.

Methylo-iodide B'Mel. Crystals. S. c. 10

at 100°.

Strychnine sulphonic acid C₂₁H₂₁(SO₃H)N₂O₄. Formed by dissolving dry strychnine sulphate in fuming H₂SO₄ (containing 30 p.c. anhydride extra) in the cold and allowing to stand a fortinight (Loebisch a. Schoop, M. 6, 857). Deliquescent mass. Does not give the strychnine reaction with K₂Cr₂O₄ and H₂SO₄. Strychnine sulphonic acid. Formed by

Strychnine sulphonic acid. Formed by heating strychnine with H₂SO₄ (2 pts.) at 100° (Stoehr, B. 18, 3429; Guareschi, G. 17, 109). Amorphous powder, v. sl. sol. water and alcohol, sol. dilute acids and alkalis. Does not give a colour with K₄Cr₂O₂ and H₂SO₄. Not poisonous.—NH₄A': v. sol. water, insol. alcohol.—KA': m. sol. water.—BaA'₂: amorphous pp.

Strychnine disulphonic acid

 $C_{21}H_{20}(SO_3H)_2N_2O_3$. Got by heating strychnine with H_2SO_4 and SO_5 at 150°. Amorphous, v. sol. water, v. sl. sol. benzene, insol. alcohol and ether.—Na₂A" 6aq.—BaA": plates, sol. water.—BaA" 7aq.—Ba(HA"):: vellow powder.

v. Sol. water, v. Sh. sol. belizens, insol. account and ether.—Na, A" 6aq.—BaA": plates, sol. water.—BaA"7aq.—Ba(HA"),: yellow powder.

STRYPHNIC ACID C, H₃N₃O₂. Got by adding HOAc to a mixture of uric acid and KNO₂ and evaporating (Gibbs, B. 2, 341). Small pale-yellow crystals, sol. hot water. Sodium-amalgam forms crimson crystals. — KA' 1½aq: yellow needles.—MgA', 6aq.—CaA', 2aq.—SrA', 6aq.—BaA', 2aq.—PhA', -Ph₂A', O3aq.

STYCERIC ACID v. PHENYL-GLYCERIO ACID.

STYCERIC ACID v. PHENYL-GLYCERIC ACID.

STYCERIN CHPh(OH).CH(OH).CH_OH.

Formed by heating CHPhBr.CH_Br.CH_OH (v.
DI-BROMO-PHENYL-PROPYL ALCOHOL) with 30 pts.

water and some AgOAc at 150°-165° (Grimaux,
J. 1873, 404). Yellow gummy mass with bitter
taste. V. sol. Aq and alcohol, nearly insol. ether.

STYPHNIC ACID v. TRI-NITRO-RESORCIN.
STYRACIN v. Cinnamyl ether of Cinnamic
ACID.

STYRENE C₃H₈ i.e. C₄H₄.CH:CH₂. Styrol. Styrolene. Cinnamene. Phenyl-ethylene. Mol. w. 104. (144°) (Schiff, A. 220, 93). S.G. 2° 9074. µ_p = 1·541 (Madan, C. J. Proc. 1, 107). S.V. 131 (Schiff). R_∞ 58·1 (Nasini a. Bernheimer, G. 1, 93). Occurs in liquid storax (Bonastre, J. Ph. 17, 338; Simon, A. 31, 265; Blyth a. Hofmann, A. 52, 293, 325) and in coal tar (Berthelot, A. Suppl. 3, 368; Krämer a. Spilker, B. 23, 3282).

Formation.—1. By distilling cinnamic acid alone or with lime or baryta (Gerhardt a. Cahours, A. Ch. [3] 1, 96; Kopp, C. R. 53, 634; Howard, C. J. 13, 135; Kraemer, Spilker, a. Eberhardt, B. 23, 3269).—2. By distilling cupric cinnamate (Hempel, A. 59, 316).—3. By distilling balsam of Peru with pumice (Scharling, A. 117, 184).—4. By distilling dragon's blood alone or with zinc-dust (Glénard a. Bondault, A. 53, 325; Bötsch, M. 1, 610).—5. By heating acetylene at a dull-red heat (Berthelot, C. R. 62, 905, 947; A. 141, 181).—6. By passing ethylene alone or mixed with benzene or diphenyl through a redhot tube (Berthelot, Z. [2] 4, 884; A. 142, 257; Barbier, O. R. 79, 660; Ferko, B. 20, 660).—7. By passing ethyl-benzene through a red-hot tube (Berthelot, Z. [2] 4, 589).—8. By heating C.H., CH., CH., Br alone or with alcoholic potash

at 180° (B.; Thorpe, Z. 1871, 130).—9. By heating C₄H₄.CHBr.CH₂ with alcoholic KCy (Radziszewski, B. 7, 140).—16. By distilling C₄H₄.CH(OAc).CH₄ (R.).—11. By heating C₅H₄.CH(OH).CH₄ (derived from acetophenone) with ZnCl₂ (Emmerling a. Engler, B. 4, 147).—12. By the action of acetylene on benzene inpresence of AlCl₃ (Varet a. Vienne, Bl. [2] 47, 918; C. R. 104, 1375).—18. From phenyl-acetylene, zinc, and HOAc (Aronstein a. Hollemann, B. 22, 1184).

Properties.—Oil, with aromatic odour. Inactive to light (Van't Hoff, Bl. [2] 25, 175). Miscible with alcohol and ether. Changes on keeping, or on heating in a sealed tube at 300°, to solid metastyrone. Combines with Cl₂ and Br₂. HBr forms C₂H₂.CHBr.CH₃. HCl forms PhOHCl.CH₂ only (Schramm, B. 26, 1709). Potash has no action. Fuming HNO₃ forms nitro-styrene. Chromic acid mixture forms benzoic acid. Cono. H₂SO₄ changes it to metastyrene. On heating with aqueous NaHSO₃ at 120° styrene forms the compound C₃H₂.NaHSO₃ (306°) (W. von Miller, N. R. P. 24, 31). Condenses, in presence of H₂SO₄, with toluene and xylene, forming diphenyl-propane and phenyl-tolyl-propane respectively (Kraemer a. Spilker, B. 23, 3169).

Metastyrene (C₃H₃)z. S.G. ½ 1054. μ₀
1.593 (Madan, C. J. Proc. 1, 107). Occurs in

Metastyrene (C_8H_8)_x. S.G. ¹² 1'054. μ_D 1'593 (Madan, C. J. Proc. 1, 107). Occurs in liquid storax (Kovalevsky, A. 120, 66). Formed from styrene on keeping or on heating in a sealed tube at 200°. Formed also by heating styrene with aqueous NaHSO_x at 110° (Miller, A. 189, 341). Transparent solid without tasto or smell, becomes sticky when warmed. Highly refractive. Insol. water and alcohol, sl. sol. ether. Inactive to light (Van't Hoff, B. 9, 1339; cf. Berthelot, C. R. 85, 1191). Changes to styrene on distillation. Cl and Br act slowly, forming the same compounds as with styrene.

Di-styrene C₁₆H₁₆i.e. Ph.CH:CH.CHMe.Ph(?). (c. 315° i.V.). S.G. 2 1-027; ¹⁵ 1-016. V.D. 7-07 (calc. 7-2). Got by boiling cinnamic acid with H₂SO, (1 vol.) and water (1½ vols.) (Erlenmeyer, A. 135, 122; Fittig a. Erdmann, A. 216, 187). Liquid, with blue fluorescence, which slowly disappears. Inactive to light. If kept boiling for a long time it decomposes, forming toluene, styrene, high boiling products, and

probably iso-propyl-benzene.

Reactions.—1. Chromic mixture gives benzoic scid.—2. Bromine gives the di-bromide $C_{15}H_{15}Br_2$ [102°], crystallising from ether in needles. V. e. sol. CS_2 , ether or benzene, v. sol. hot alcohol.

Solid distyrene $C_{1a}H_{1e}$. [119°]. A product of the distillation of cinnamic scid or of its Ca salt (Engler a. Leist, B. 6, 256; Miller, A. 189, 840). Formed also by passing C_0H_1 , C_1H_2 , over red-hot lime (Radziszewski, B. 6, 494). Tables. Yields a dibromide $C_{1e}H_{1e}Br_2$ [238°], crystallising from benzene in needles (Liebermann, B. 22, 2256).

References.—Amido-, Bromo-, Bromo-amido-, Bromo-nitro-, Chloro-, Chloro-, Nitro-,

and NITRO-AMIDO-STYRENE.

STYRENE DIBROMIDE v. DI-BROMO-ETHYL-BENZENE.

STYRENE DICARBOXYLIC ACID C_{1e}H₄O₄
i.s. [1:2] CO₂H.O₂H₄.CH:CH:CO₂H. o-Carboxycimamicacid. [175°]. Formed by heating the salts
of oxy-carboxy-phenyl-propionic acid (Gabriel

a. Michael, B. 10, 1558, 2200). Slender needles (from water). Changed on fusion into the lactone of oxy-carboxy-phenyl-propionic acid.—PbA".—Ag,A": sticky pp.

Isomeride v. p-Carboxy-cinnamic acid, vol. ii, p. 190.

STYRENE DICHLORIDE v. wa-Di-Chloro-DI-ETHYL-BENZENE.

STYRENE DI-IODIDE V. DI-IODO-ETHYL-

STYRENE DISULPHOCYANIDE C_sH_s(SCN)₂. [102°]. Formed by heating C_sH₃CHBr.OH₂Br with potassium sulphocyanide in alcohol (Nagel, A. 216, 323). Pale-yellow needles, v. sol. ether, hot benzene, and toluene. Crystallises from benzene as C₁₆H₈S₂N₂C₆H₈ [62°]. Alcoholic ammonium sulphide at 100° forms (C₈H₈)₂S [151°]. Cold fuming HNO₂ gives rise to the compound [1:4] C₈H₄(NO₂).CH(SCy)CH₂(SCy) [112°] crystallising from alcohol in needles.

DI-STYRENIC ACID C17H16O2 6.6.

Ph.CH:CH.CPhH.CH₂CO₂H or Ph.CH:CH.CH.(CO₂H).CH₂Ph. Formed by boiling cinnamic acid with H₂SO₄ (1 vol.) diluted with water (1 vol.) (Fittig a. Er³mann, 4. 216, 182). White amorphous powder. V. sl. sol. water, v. e. sol. ether, alcohol, or glacial acetic acid. It melts below 50°. May be distilled almost undecomposed.

Reactions.—I. Sodium amalgam has no action.—2. Br in CS₂ forms no bromide.—3. Boiling H₂SO₄ (I vol.) mixed with water (1½ vols.) does not affect it.—4. Chromic mixture gives only benzoic acid.

Salts.— $Ca(C_i, H_i, O_s)_s$.— BaA'_s — AgA'_s . Ether.—EtA'. Liquid.

STYROGALLOL $C_{ie}H_sO_s$ i.e.

C₆H₁<C_C>C₆H(OH)₂
CH.CO — >0 (?). Formed from e cinnamic acid, gallic acid, and conc. H₂SO₄ at

cinnamic acid, gallic acid, and conc. H₂SO₂ at 50° (Jacobsen a. Julius, B. 20, 2588; von Kostanecki, B. 20, 3137). Yellow needles, which may be sublimed; al. sol. hot alcohol. Not melted at 350°. With mordants it dyes like nitro-alizarin.

STYROLENE ALCOHOL v. DI-OXY-ETHYL-BENZENE.

STYRONE v. CINNAMYL ALCOHOL.

STYRONE DIBROMIDE v. (di)-Bromo-PHENYL-PROPYL ALCOHOL.

STYRYL-ACRYLIC ACID v. PHENYL-PEN-TINOIC ACID.

STYRYIP AMYL KETONE CARBOXYLIC ETHER CI, H₂O₃ i.e. C₆H₃.CH:CH.CO.OEt₄.CO.₂Et. [102°]. Formed from di-ethyl-acetoacetic ether, benzoic aldehyde, and HCl in the cold (Claisen a. Matthews, A. 218, 184). Triclinic prisms (from ligroin). Yields C₁,H₂₂Br₂O₃ [55°] orystallising in small prisms.

STYRYL-ANGELIC ACID C, H, O, i.e. C, H, OH:CH.CH:CEt.CO, H. [127]. Formed by heating cinnamic aldehyde with butyric anhydride and sodium butyrate at 165° (Perkin, C.J.

dride and sodium butyrate at 165° (Perkin, C. J. 81, 413). Crystals, v. sol. alcohol.—AgA'.

STYRYL BUTENYL KETONE C_{1:}H₁, O i.e.
C₄H₂, CH:OH:OO.OH:OMe₂ (179° at 14 mm.).

Formed by passing HCl into a mixture of bensoic aldehyde and mesityl oxide (Claisen a. Claparède, B. 14, 351). Yellowish liquid, smelling like strawberries. Yields C_{1:}H₁, Br₄O [180°].

FORMAL OROTONIC ACID C₁₂H₁₂O₂. [158°]. Formed by heating cinnamic aldehyde with propionic anhydride and sodium propionate (Perkin, C. J. 31, 413). Prisms (from ligroin).—AgA': white pp. sl. sol. sold water.

STYRYL ETHYL KETONE CARBOXYLIC ACID C₄H₁.CH₂CO₂H. Cinnamatoric Charles (Contraction of the Contraction of the Cont

moyl-propionic acid. Benzylidene-levulic acid. [120°]. Formed from β-acetyl-propionic acid, benzoic aldehyde, and dilute KOHAq (Erdmann, A. 258, 130). Leaflets (from water). May be reduced to C.H., CH., CH., CO.CH., CH., CO., Ethy. Co.,

C.H. CH:CH.O.C.H. (217°). S.G. 981. Formed from w-chloro-styrene and NaOEt at 180° (Erlenmeyer, B. 14, 1868). Aromatic liquid. Converted by heating with water into alcohol and phenyl-acetic aldehyde.

STYRYL-ETHYL-PYRIDINE C, H, N

i.e. C.H.CH:CH.CCOH:CH basole. [58°]. (356° cor.). Formed by heating methyl-ethyl-pyridine with benzoic aldehyde and ZnCl, at 220° (Plath, B. 21, 3087). Needles or plates, insol. water, v. sol. alcohol and ether, sl. sol. ligroin. Bromine yields the dibromide C.H., CHBr.CHBr.C.H., EtN. [128°]. — B'HCl. C₄H₁, OHDF OHDF C₅H₁, EtN. [128°]. — B HCI. [193°]. — B'₂H, PtCl₄ 2aq. [188°]. Needles.— B'HAuOl., [168°].—B'HSnCl₃ 3aq. [246°].— B'HHgCl₃, [196°].—B'C₄H₃N₃O₇. [203°]. STYRYL-GLYOXAL. Oxim C₁₆H₅NO₂ i.e. C₄H₅CH:CH.CO.CH:N.OH. [144°]. Formed from

nitroso-acetone, benzoic aldchyde, and alcoholic NaOEt (Claisen a. Manasse, B. 22, 529). Crystals (from water or benzene). Gradually decomposes, with evolution of HCy.

STYRYL-GLYOXYLIC ACID C, H,O, i.e. C.H..CH:CH.CO.CO.H. Formed by saponification of its amide by conc. HClAq, and also by saturating a mixture of benzoic aldehyde and pyruvic acid with HCl (Claisen, B. 13, 2124; 14, 2472). Gummy mass, sol. water. Split up by alkalis, even in the cold, into benzoic aldehyde and pyruvic acid.—AgA': pp.

Amide CHPh:CH.CO.CO.NH. [130°]. pared by the action of conc. HClAq and HOAc on the nitrile of cinnamic acid. Flat prisms or

plates. Sol. ether and hot water.

Reference. - NITRO-STYRYL-GLYOXYLIC ACID. STYRYL-HYDANTOIC ACID C,,H,,N,O. [185°]. Formed by boiling styryl-hydantoin with baryta water (Pinner a. Spilker, B. 22, 692). White plates, sol. alcohol and hot water. Boiling HClAq converts it into styryl-hydantoin.—AgA'.

STYRYL-HYDANTOÏN v. DI-OXY-STYRYL-m-PYRAZOLI STYRYLIDENE-THIO-GLYCOLLIC ACID v.

CINNAMYLIDENE-THIO-GLYCOLLIC ACID.

DI-STYRYL-KETONE v. DI-BENZYLIDENE-ACETONE and NITRO- and OXY- DI-STYRYL-KETONE. STYRYL-DI-METHYL-GLYOXALINE

 $C_{19}H_{14}N_{2}$ i.e. $C_{0}H_{1}CH:CH.C \leqslant_{N-CMe}^{NH.CMe}$ Formed from di-methyl di-ketone, cinnamic aldehyde, and alcoholic ammonia at 100° (Wadsworth, C. J. 57, 11). Crystals, v. sol. alcohol.—B',H.PtCl_a: minute yellow needles.
STYRYL METHYL KETONE t. BENZYLIDENE-

ACRIONE and Nitro- and Oxy- STYRYL METHYL

STYRYL METHYL KETONE CARBOXYLIG ETHER C. BENZYLIDENE-ACETOACETIC ETHER. vol. i. p. 24.

STYRYL.METHYL.OXAZOLE DIHYDRIDE

 $C_eH_eCH:CH.C \leq_{N.CH_2}^{O.CHMe}$. [817]. Formed from '8-bromo-propylamine hydrobromide, cinnamoyl

chloride, and alcoholic potash (Elfeldt, B. 21, 3226). Transparent crystals.— B'₂H₁PtCl₂, [198°].—B'C₆H₁N₁O₇. [183°]. Needles.

STYRYL-METHYL-PYRIDINE C₁₄H₁₃N

i.e. C.H., OH: OH. O.H., Melhyl-stilbazole. (c. 323°). S.G. 2 1-0717. Formed by heating benzoic aldehyde with (αγ)-di-methyl-pyridine and ZnCl, at 215° (Bacher, B. 21, 3072). Oil, v. sol. alcohol and ether. Gives $C_{1i}H_{13}Br_{.2}N$. [140°]. May be reduced to $C_{1i}H_{13}N$ (c. 293°) and C, H2N (c. 288°).-Hydroiodide. [211°]. B'.H.PtCl6aq. [183°].—B'HAuCl,. [142'].— B'HĤgCl₃.—B'C₆H₃N₃O₇. [193°]. Yellow needles.

STYRYL-DI-METHYL-PYRIDINE DICARB-

 $\begin{array}{ll} \textbf{OXYLIC ACID } \textbf{C}_{11}\textbf{H}_{12}\textbf{NO}_{4} \\ \textbf{\textit{i.e.}} \textbf{ C}_{6}\textbf{H}_{3}.\textbf{CH}:\textbf{CH}.\textbf{C} \\ \textbf{C}_{(CO_{2}}\textbf{H}):\textbf{CMe} \\ \textbf{N.} \end{array} \hspace{-0.5cm} \textbf{N.} \hspace{0.5cm} \textbf{[241°]}.$

Formed from its ether, which is got by the action of nitrous acid gas on an alcoholic solution of the dihydride C₂₁H₂₃NO₄ [149°], obtained from cinnamic aldehyde, acetoacetic ether, and alcoholic NH, (Epstein, A. 231, 1). Minute colourless tablets (containing 2aq), sl. sol. water, sol. alcohol. Melts at 219° when hydrated. Converted by hypochlorous acid into C₁, H₁₈NO, 2aq (Messinger, B. 19, 196).—K₂A" 3aq. —(H₂A")₂H₂PtCl₈.—H₂A"HCl. Decomposed by water.

Ethylether Et, A". [39°]. Yields the salt (Et,A"),H2PtCl, [195°].

STYRYL-METHYL-THIO-GLYCOLLIC ACID v. CINNAMYL-THIO-GLYCOLLIC ACID.

STYRYL-(a)-NAPHTHOQUINOLINE

C₂₁H₁₅N i.e. C₆H. CH:CH:CH

-C. N ;C.CH;CHPh. [104°]. Formed by distilling the carboxylic acid

 $C_{10}H_6$ < $C(CO_2H):CH$ C.CH:CHPh [256°], which is

got by the action of (a)-naphthylamine on cinnamic aldehyde and pyruvic acid (Döbner a. Peters, B. 23, 1233). Concentric groups of yellowish needles, sl. sol. alcohol.—B'2H,PtCl, 2aq: orange-yellow pp. - B'2H2Cr2O7. - B'C4H2N3O7. [230°]. Golden needles.

Carboxylic acid C₂H₁₈NO. [256°]. Yields BaA'₂2aq, CuA'₂ aq, and AgA'. Styryl-(β)-naphthoquinoline

[175°].

Formed in like manner from (β) -naphthylamine. White silky needles or pearly plates.—Salts: B'2H2PtCl8 2aq. - B'2H2Cr2O7. - B'CH3N3O7.

[254°]. Golden needles, sl. sol. ether. Carboxylic acid C₂₂H₁₅NO₂. Lemon-yellow needles, sl. sol. hot alcohol.

STYRYL-OXAZOLE DIHYDRIDE C,H,NO i.e. C₆H₅CH:CH.C (O.CH₂. [58°]. Formed from CH.Br.CH., NH.CO.CH:CHPh and alcoholic potash (Elifeldt, B. 24, 3225).—B',H.PtCl. r194°]. Orange-yellow powder. B'C, H, N, O, [189°]. Yellow needles.

· STYRYL-PENTOXAZOLE DIHYDRIDE

C,H,CH:CH.O (0.CH, OH, [56°]. Formed' by the action of alcoholic potash on the y-bromopropyl-amide of cinnamic acid (Elfeldt, B. 24, 8227). Needles.—B',H.,PtCl., Decomposes at 198°.—B'C,H,N,O,. [196°].
STYRYL-PHENOL v. OXY-DI-PHENYL-ETHYL-

(a)-STYRYL-PYRIDINE C,H,, N i.e.

C.H.CH:CH.O CH:CH CH. Stilbazole. [91°]. (325° cor.). Formed by heating benzoic aldehyde with methyl-pyridine and ZnCl, at 220° (Baurath, B. 20, 2719; 21, 818). Crystals, m. sol. alcohol.

Reactions.—1. Br forms $C_{13}H_{11}Br_2N$ [167°]. 2. HIAq reduces it to $C_{13}H_{13}N$ [-3°].—3. Na and HOEt reduce it to C12H13N (288° cor.).

Salts.—B'HCl 4aq: needles. Melts at 177° when anhydrous.—B'₂H₂PtCl₆ 2aq. [188°]. Red needles.—B'HAuCl₄. [185°]. — B'HHgCl₅ aq. [183°].—B'HI₄. [159°]. Prisms, with blue reflex. Reference.—OXY-STYRYL-PYRIDINE.

(Py. 3)-STYRYL-QUINOLINE C17H13N i.e.

C_eH, CH:CH N:C.CH:CHPh. [100°]. Formed by distilling its carboxylic acid (Doebner a. Peters, B. 22, 3008). Got also by heating (Py. 3)methyl-quinoline with benzoic aldehyde and ZnCl₂ (Wallach, B. 16, 2008; Jacobsen Reimer, B. 16, 2606). Crystals. Yie Yields C17H18Br2N [1740] .- Salts: B'2H2PtCl, 2aq.-B'H,Cr2O, 21aq.

References .- NITRO- and OXY- STYRYL-QUIN-

OLINE.

STYRYL-QUINOLINE CARBOXYLIC ACID

C₆H₄< C.CH:CHPh [295°]. Formed from cinnamic aldehyde, pyruvic acid, and aniline in alcohol (Doebner a. Peters, B. 22, 3006). Yellow needles, insol. water, sl. sol. ether.—

MgA'₂: concentric groups of needles.

STYRYL-QUINOLINE SULPHONIC ACID
C₂H₄(SO₂H)N.CH:CHPh. Formed by heating (Py. 1)-methyl-quinoline (B. 2)-sulphonic acid with benzoic aldehyde and ZnCl, for six hours at 170° (Busch a. Koenigs, B. 23, 2682). Crystals (containing 2aq). V. sol. 50 p.c. acetic acid. STYRYL THIENYL KETONE C₁₈H₁₀SO i.e.

C₆H₂CH:CH.CO.C₄H₃S. [80°]. Formed by passing HCl into a mixture of thienyl methyl ketone and benzoic aldehyde (Brunswig, B. 19, 2895). Needles. Yields a dibromide C₁₈H₁₀Br₂SO [157°] crystallising from alcohol in plates

DI-STYRYL-DI-VINYL KETONE v. DI-PHENYL-DI-BUTINYL KETONE

STYRYL-VINYL METHYL KETONE v.

PHENYL-BUTINYL METHYL RETONE.

SUBERCOLIC ACID C.H. (CO.H). in small quantity by the action of alcoholic potash on di-bromo-suberic acid (Hell a. Rempell, B. 18, 820). White powder, yielding at 2250-230° a sublimate of slender white needles.— BaA".—CaA".—MgA" 2aq.—Ag₂A": white pp. SUBERCONIC ACID. [165°-170°]. A crys-

talline product of the action of alcoholic potash on bromo-suberic acid (Ganttner a. Hell, B. 15,

149). SUBERENE CARBOXYLIC ACID C.H. O [54°]. Formed by boiling chloro-suberonie said by heating suberic said (1 pt.) with aniline

C.H., ClO, with NaOHAq (Spiegel, A. 211, 119). Pearly plates, volatile with steam. Reduced by sodium-amalgam to suberane carboxylic acid C.H.,O.

SUBERIC ACID C₂H₁₄O₄. Mol. w. 174. [140°]. (c. 800°). (279° at 100 mm.) (Krafit, *B. 22, 816). S. 142 at 15°. S. (ether) 8 at 15°. H.C.p. 992,409 (Louguinine, C. R. 107, 597); 985,600 (Stohmann, J. pr. [2] 40, 215). H.F. 249,400 (S.).

Formation .- 1. By the action of nitric acid upon cork (Brugnatelli, Crell. Ann. 1787, i. 145; Bouillon-Lagrange, A. Ch. 23, 2; J. Ph. 8, 107; Chevreul, A. Ch. 62, 323; 96, 182; Brandes, S. 32, 393; 33, 83; 36, 263; A. 9, 295; Bussy, J. Ph. 8, 107; 19, 425; Boussingault, J. pr. 7, 211; Harff, N. Br. Arch. 5, 303).—2. By the action of nitric acid upon oleic and stearic acids (Laurent, A. Ch. [2] 66, 157; Bromeis, A. 35, 89), upon castor oil (Tilley, A. 39, 166; Dale, A. 132, 244; 199, 145; Grote, A. 130, 208), upon inseed oil (Saco, A. 51, 222), upon cooca-nut oil (Wirtz, A. 104, 261), upon almond oil, upon spermaceti (Arppe, A. 120, 292; 124, 89), upon palmitolic acid (Schröder, A. 148, 33), upon paraflin (Pouchet, C. R. 79, 320), upon palm oil (Ganttner a. Hell, B. 13, 1165; 14, 1549), and upon myristic acid (Noerdlinger, B. 19, 1896) .-3. Occurs among the products of the distillation of crude fatty acids in superheated steam (Cahours, C. R. 94, 610).—4. From di-oxy-steario acid and alkaline KMnO, (Spiridonoff, J. pr. [2] 40, 250).—5. Suberic ether is formed by the electrolysis of CO₂Et.CH₂.CH₂.CH₂.CO₂K, the yield being 28 p.c. of the theoretical amount (Crum Brown a. Walker, A. 261, 120).

Properties.-Long needles (from water) or tables. May be sublimed in needles. Not volatile with steam.

Reactions .-- 1. Yields hexane when distilled with baryta .- 2. Forms suberone on distilling with lime .- 3. Bromine at 160° forms bromoand di-bromo-suberic acids, which when boiled with potash yield oxy- and di-oxy- suberic acids (Gal a. Gay-Lussac, C. R. 70, 1175).

Amide C.H., N.O. Crystalline. Amic acid C. H.; (CONH.). CO.H. [c. 170°]. Formed by distilling ammonium subcrate. Crystalline, v. sol. hot water.

Anilide C.H.; (CO.NHPh), [188°]. Formed

(1 pt.) (Gerhardt a. Laurent, A. Ch. [8] 24, 185).

Pearly plates (from alcohol), v. sol. ether.

Phenylamic acid C₆H₁₂(CO.NHPh).CO₂H. Formed at the same time as the anilide. Minute laminæ, sl. sol. hot water.—AgA': white pp

References .- Bromo . CHLORO . and Oxy-SUBERIC ACID.

Isosuberic acid is DI-ETHYL-SUCCINIC ACID (Hell, B. 22, 67)

SUBERIC ALDEHYDE C₈H₁₄O₃. (202°). A product of the action of fuming HNO₃ on palmitolic acid (Schröder, A. 143, 34). Oil, partially decomposed by distillation. Oxidised by bromine water to suberic acid.

SUBEROCARBOXYLIC ACID v. HEXANE TRICARBOXYLIC ACID.

SUBEROMALIC ACID v. OXY-SUBERIC ACID. **SUBERONE** C₂H₁₂O. Mol. w. 112. (180° i.V.). V.D. 3.73 (calc. 3.89). Formed, together with hexane, by distilling subcric acid with lime (Boussingault, A. 19, 308; Tilley, A. 39, 167; Dale a. Schorlemmer, C. J. 27, 935; A. 199, 147; Wislicenus, A. 275, 356). Colourless liquid, smelling like peppermint. Oxidised by HNO, (S.G. 1.4) to n-pimelic acid [102°]. Does not reduce AgNO, or Fehling's solution. Combines with bromine, forming a product which, when distilled over KOH, gives C₁H₁₂O (Ladenburg, B. 14, 2406). Combines with HCy yielding C₁H₁₂(OH)CN, which is converted by HCl into suberyl-glycollic acid C₂H₁₂(OH).CO₂H [80°], from which conc. HClAq at 130° produces chloro-suberane carboxylic acid C,H12Cl.CO2H, a thick oil, converted by KOH into suberene carboxylic acid C,H₁₁.CO₂H [54°], which may be reduced by sodium-amalgam to suberane carboxylic acid C.H,3.CO2H, and this may be oxidised by HNO, to a dibasic acid $C_aH_{14}O_4$ or $C_aH_{12}O_4$ (Dale a. Schorlemmer, C. J. 39, 539; Spiegel, A. 211, 117). Suberone is reduced in alcoholic solution by sodium to C,H,O, a colourless liquid, with mouldy smell (185°), S.G. $\frac{15}{15}$ 9595, which unites with phenyl cyanate forming C,H,3O.CO.NHPh [85°], and also with HI forming a compound which is converted by alcoholic potash into suberonylene C,H₁₂ [114.5°] and a little C,H₁₃OEt. The compound C,H,O is reduced by conc. HIAq at 250° to C,H, Suberonylene combines with bromine (Markownikoff, C. R. 110, 466).

Oxim C,H,2:NOH. Liquid, smelling like peppermint, sol. alcohol, ether, alkalis, and acids (Nägeli, B. 16, 497). Reduced by sodiumamalgam to C, H13.NH

SUBERO-TARTARIC ACID v. DI-OXY-SUBERIO ACID.

SUBERYL-GLYCOLIC ACID v. Oxy-suberanic ACID.

SUBLIMATION. The passage of a solid body, when heated, to the state of vapour without melting. The temperature of sublimation is definite for every solid, and is dependent on the pressure. There is a definite pressure for each definite solid below which the substance cannot exist as a stable liquid, so that if heated below this pressure it passes from the solid directly to the gaseous state; but if heated under pressures greater than this pressure the substance first liquefies and then vaporises. As the definite pressure is considerably below that of the atmosphere for most substances, but few bodies undergo sublimation, properly so called, when heated under ordinary conditions. Sublimation is treated fairly fully in Thorpe's DICTIONARY OF AP-PLIED CHEMISTRY (vol. iii. p. 609), and instances are given where the process is made use of it M. M. P. M. manufacturing operations.

SUBSTITUTION. The replacement of one element in a compound by another element is the primary meaning given to the term 'substitution.' As our ways of looking at composition, and changes of composition, are saturated with the conceptions of the molecular and atomic theory, substitution is better described as the replacement of an atom in a molecule by another atom. But the term must be widened to include cases wherein an atom is replaced by a group of atoms, which group is regarded in that reaction as if it were a single atom. The moment attention is paid to the number of atoms that can be substituted for some specified atom in a molecule the conception of chemical equivalency is found necessary to give a common foundation to the facts that are observed (v. EQUIVALENCY, vol. ii., especially pp. 449-451). The properties of a molecule are changed by the substitution of an atom or atomic group in the place of one, or more, of the atoms in the original molecule; the prosecution of the inquiry into the connections between the properties of molecules derived, by substitution, from some parent molecule leads to the hypothesis of types, which is afterwards merged in the wider subject of chemical classification (v. Classification, Chemical, vol. ii. p. 196; EQUIVALENCY, vol. ii. pp. 450-451; TYPES, in this vol.).

Experiments show that the substitution of a more positive by a less positive atom, or atomic group, is accompanied by a change of properties in the direction that the substitution-product is more acidic than the parent substance. This field of inquiry has been cultivated systematically in recent years, and measurements have been made of the effects of substitution-changes of the kind indicated on the affinities of many acids. The results obtained have led, and are leading, to new conceptions of the nature of allinity, and of the constitutions of molecules (v. Physical methods, section Electrical methods, pp. 197-207 in this vol.).

M. M. P. M. SUCCINAMIDINE C,H,N, i.e.

CH₂.C(NH₂)NH. Formed by the action of CH₂.C(NH₂) ammonia on succinic-di-imido-di-ethyl ether C₂H₁(C(OEt):NH)₂ (Pinner, B. 16, 362, 924, 1643, 1655). The salt B"2HCl forms minute needles, dissolving in water with formation of NH₁Cl and succinimidine C2H4(NH)3.

SUCCINAMIDOXIM C2H4(C(NH2):NOH)20 Succinene diamidoxim. [188°]. Formed by adding hydroxylamine hydrochloride and Na₂CO₂Aq to an alcoholic solution of the nitrile of succinic acid (Sembritzki, B. 22, 2958). Crystals, sol. hot water, sl. sol. hot alcohol, insol, ether. Coloured reddish-brown by FeCl, insol. ether. Coloured reddish-brown by FeUl₃. Fehling's solution gives a dirty green pp. Ac₂O forms C₂H₄(C(NH₂):NOAc), [168°]. NaOEt and EtI form C₂H₄(C(NH₂):NOEt), [119°]. BzOl and NaOH produce the benzoyl derivative C₂H₄(C(NH₂):NOBz), [192°], crystallising in needles, converted by heating with water at 159° into $C_2H_4(C < \stackrel{N.O}{N})$ CPh), [159°]. Aqueous potassium evanate and HCl form $C_2H_4(C(NOH).NH.CO.NH_2)$, [164°].

ous potassium oyanate and HCl form $C_1H_1(C(NOH).NH.CO.NH_2)_2$ [164°].

Succinimidoxim $C_1H_2(C(NOH))$ NH. Formed by heating the nitrile of succinic acid with hydroxylamine at 65° (Sembritzki, B. 22, 2964). Prisms (containing 2aq). Sol. hot water, insol. alcohol. Alcoholic NaOH forms a blue solution turning green. FeCl₃ gives a dark-violet colour.—

Ag₂C,H₃N₃O₂: pearly plates.

Di-acetyl derivative C₄H₃Ac₂N₃O₂.

[171°]. Crystalline powder, sol. water.

Di - benzoyl derivative C,H,Bz,N,O,.
[189°]. Crystals, insol. water, sol. hot alcohol.
SUCCINIC ACID C,H,O, i.e.
CO,H.CH,,CH,CO,H. Mol. w. 118. [182°]

CO₂H.CH₂.CH₂.CO₂H. Mol. w. 118. [182°] (Kräfft a. Noerdlinger, B. 22, 816; Reissert, B. 23, 2245); [185°] (Davidoff, B. 19, 406). (261°). S.G. 1·55. S. 2·88 at 0°; 5·14 at 14·5°; 121 at 100° (Bourgoin, Bl. [2] 21, 110; 29, 243; Miczynski; M. 7, 263). S. (alcohol) 7·5 at 15°. S. (ether) 1·25 at 15°. H.C.v. 357,100. H.C.p. 356,800. H.F. 226,200 (Stohmann, J. pr. [2] 40, 207); 229,000 (von Rechenberg). S.H. ·290 (from 0°-50°); 365 (0°-150°) (Hess, A. Ch. [2] 35,410). Heat of Neutralisation: Gal a. Werner, C. R. 103, 871.

Occurrence.-In amber (Agricola ; Berzelius. A. Ch. 94, 187; Lecanu a. Serbat, J. Ph. 8, 541; 9, 89; Liebig a. Wöhler, P. 18, 162; D'Arcet, P. 36, 80), in turpentine from several species of pine, in Chelidonium majus (Walz, N. J. P. 15, 22; Zwenger, A. 114, 350), in lettuce (Köhnke, B. J. 25, 443), in Papaver somnifcrum, in unripe grapes (Brunner a. Brandenburg, B. 9, 982), in exudations from the bark of mulberry trees (Goldschmiedt, M. 3, 136), in beet juice (von Lippmann, B. 24, 3299), and in rhubarb (Brunner, B. 19, 595). Occurs also in the thymus gland of the calf, the spleen of the ox (Gorup-Besanez, A. 98, 28), in certain pathological exudations (Heintz, A. 76, 369; Brieger, H. 5, 368), in the urine of rabbits fed on carrots (Meissner a. Jolly, J. 1865, 675; cf. Salkowski, Pf. 4, 91), and in human urine after eating asparagus (Hilger, A. 171, 208).

Formation.—1. By the action of HNO, on many organic substances, including fats, fatty acids from butyric acid upwards, wax, spermaceti, sebacic acid, and azelaic acid (Bromeis, A. 35, 90; 37, 292; Sthamer, A. 43, 346; Ronalds, A. 43, 356; Radcliff, A. 43, 351; Arppe, A. 95, 242; Dessaignes, A. 70, 102; 74, 361; Erlenmeyer, B. 7, 696; Noerdlinger, B. 19, 1895). - 2. In the alcoholic fermentation of sugar (Pasteur, Bl. 1852, 52; A. 105, 264).—3. In the fermentation of asparagine (Piria, A. 68, 343), of calcium malate (Dessaignes; Liebig, A. 104, 363), of ammonium tartrate (König, B. 14, 211), and of flesh (Sal-kowski, B. 12, 649).—4. By reducing fumaric and maleic acids with sodium-amalgam (Kekulé, A. Suppl. 1, 133).—5. By reducing malic and tartaric acids with HI (R. Schmitt, A. 114, 106; Dessaignes, A. 115, 120; 117, 134).—6. By heating its nitrile (ethylene cyanide) with alcoholic potash at 100° (Maxwell Simpson, A. 118, 373), or by treating it with dilute nitric acid (Jungfleisch, Bl. [2] 19, 197).—7. From bromo-acetic soid and reduced silver at 180' (Steiner, B. 6, 184).— 8. From \$\mathcal{B}\$-chloro-propionic ether by successive treatment with KCy and potash (Wichelhaus, \$Z. [2] 8, 247).—9. From sodium acetoacetic ether by treatment with chloro-acetic ether and saponification of the product (Wippermann, \$B. 3, 337; Noeddecke, \$A. 149, 224).—10. By heating ethane tricarboxylic acid at 160° (Bischoff, \$B. 13, 2162).—11. By potashfusion from gum arabic, milk sugar, and carminic acid (Hlasiwetz, \$A. 138, 76; 141, 340).—12. By reducing acetylene dicarboxylic acid with zinc and HOAc at 60° (Aronstein a. Hollemann, \$B. 22, 1183).—13. Its ether is formed by electrolysis of \$CO_Et.CH_cCO_K\$ in aqueous solution; the yield being 60 p.c. of the theoretical (Crum Brown a. Walker, \$A. 261, 115).

Preparation.—1. By distilling amber, heating the watery distillate, filtering, and allowing to crystallise. The product is freed from oils by treatment with nitric acid.—2. By neutralising tartaric acid (2 kilos) with NH_Aq, adding to the aqueous solution (40 litres) K.HPO₄ (20 g.), MgSO₄ (10 g.) and a little CaCO₃. Fermentation is started by diluting a little (5 c.c.) of the solution with water (25 c.c.) and exposing it to the air for a few days. When fermentation has set in, the liquid is returned to the main quantity, and the whole kept at 25°-30° for seven weeks. The liquid is evaporated somewhat, clarified by white

of egg, and boiled with lime. After cooling, the calcium succinate is collected and decomposed by H.SO.. The yield is good (500 g.) (Koenig, B. 15, 172).

Properties.—Monoclinic prisms, permanent in air, acid in taste. V. sol. water, m. sol. alcohol, sl. sol. ether. Resolved on boiling into water and anhydride; the lactone O,H,O, being also formed. BaCl₂ completely ppts. hot neutral solutions (Schmitt a. Hiepe, Fr. 21, 536). BaCl₂ followed by NH₂Aq and alcohol ppts. succinic (but not benzoic) acid. FcCl₃ gives in neutral

solutions a reddish-brown pp. PbAc₂ gives a pp. sol. excess.

Reactions .- 1. Not attacked by HNO, CrO, or chlorine water. MnO2 and H2SO, yield acetic acid. KMnO, in neutral solution oxidises it to oxalic acid and CO₂; and, in acid solution, to CO₂ (Berthelot, Bl. [2] 8, 390; Sorokin, J. R. 11, 383) .- 2. Yields ethylene and CO2 when decomposed in alkaline solution by an electric current (Kekulé, A. 131, 79; Bourgoin, A. Ch. [5] 20, 80; cf. Kolbe, A. 113, 244). In perfectly neutral solution only CO2, CO, and O are given off at the positive pole. - 3. Potash-fusion yields oxalic acid.-4. PCl, forms successively: succinic anhydride C2H,(CO)2O, succinyl chloride C_H_((COCI)₂, fumaryl chloride C_H_(COCI)₃, di-chloro-fumaryl chloride C_HCl(COCI)₃, di-chloro-maleyl chloride C_CI_(COCI)₂, two tetrachlorinated di-chloro-maleyl chlorides, viz.: C,Cl₂(CCl₂)(COCl) and C₂Cl₂(CCl₂)₂O (v.DI-CHLORO-MALEIO ACID), and finally per-chloro-ethane, 2C₂Cl₆ (Kander, J. pr. [2] 31, 1).—5. On long boiling it yields the dilactone of diethyl ketone s-di-ω-carboxylic acid CO.O.O.OH, CH, [75°] (c. 203° at 15 mm.), orystallising from alcohol in plates, converted by HClAq into hydrochelidonic acid CO(CH₂CH₂CO₂H)₂ [143°], which yields an oxim [129°] (Volhard, A. 258, 206).—6. Converted into succinic anhydride by treatment with

P.O. Acci, BzCl, Ac.O. or succinyl chloride (Anschütz, B. 10, 325, 1881).—7. A solution containing 5 p.c. succinic soid and 1 p.c. uranium succinate when exposed to sunlight turns green and gradually gives off CO2, leaving propionic acid in solution (Seekamp, A. 133, 253). Barium succinate (1 mol.) heated with NaOMe (1 mol.), for 3 hours at 300° yields propionic acid (Mai, B. 22, 2133).-8. Heated with a large excess of lime it yields ethane as chief product (Han-riot, Bl. [2] 45, 79).—9. The salts on distillation yield a liquid product (160°-250°) which yields benzene when distilled over zinc-dust (Von Richer, J. pr. [2] 20, 206; cf. Fumaro, G. 11, 273). Hydroquinone is also a product of the distillation of succinates .- 10. The sodium salt heated with P.S. yields thiophene (Volhard a. Erdmann, B. 18, 454).—11. The Na salt heated with aldehydes and NaOAc forms oxyacids of the form R.CH(OH).CH(CO₂H).CH₂.CO₂H (Fittig, B. 18, 2523).—12. By heating with phthalic anhydride and NaOAc at 250°, exhausting the product with water and alcohol, and boiling the residue with aniline, there is got 'diphthalsuccinanilide' C₁₀H₂₄N₂O₄ [267°] converted by boiling with HOAc and HCl into 'diphthalsuccindehydranilide ' C,0H20N2O2, crystallising from HOAc in small yellow prisms, not liquid at 280° (Roser, B. 18, 3122).—13. By heating with glycerin at 200° it yields 'succinin' C₃H₅(OH)A", a gummy mass, insol. cold water, alcohol, and ether (Fumaro a. Danesi, G. 10, 58). Alkalis and acids split it up into glycerin and succinic acid.—14. a-Chloropropionic ether and alcoholic potash give C.H. (CO.O.CHMe.CO.Et), (c. 302° at 730 mm.) (Wurtz a. Friedel, A. Ch. [3] 63, 101; Wislicenus, A. 133, 262).

Salts.—(NH₁)₂A". Hexagonal prisms, v. sol. water and alcohol. Yields succinamide when heated.—(NH₁)HA". Triclinic crystals, v. sol. water and alcohol (Brooke, Ann. Phil. 22, 286). Formed by evaporating a solution of the neutral salt.—K₂A" 2aq. Deliquescent crystals, sol. alcohol, insol. ether.—K₂A" 3aq. Trimetfic crystals (Salzer, B. 16, 3025).—KHA" 2aq. Efflorescent six-sided prisms.—NaHA". 2aq. Efflorescent six-sided prisms.—NaHA". Triclinic prisms.—NaHA" 8aq: monoclinic crystals.—BaA". Sl. sol. water, insol. NH₂Aq and alcohol. S. 42 at 8°; '48 at 12°; '28 at 67° (Miczynski).—CaA" 3aq: small needles, deposited gradually on mixing cold conc. solutions of sodium succinate and CaCl₂. On mixing the hot solutions CaA" aq is ppd. S. 1·1 at 0°; 1·3 at 24°; '8 at 68° (Miczynski, M. 7, 266).—CaH₂A", 22aq.—SrA": monoclinic prisms.—BeA" 2aq (Atterberg, Bl. [2] 21, 162).—Be₂(OH)A" 2aq.—MgA" 6aq. Prisms (Fehling, A. 49, 154).—MgK₂A",—Mg₂A", 20, aq.—CrA" aq: soarlet pp.—CuA" (dried at 200°). CuA"2NH₂.—CuA"4NH₃ (Schiff, A. 123, 45).—Fe(OH)A": brownish-red pp.—NiA" 4aq.—MnA" 4aq. Triclinic prisms (Handl, Sits. W. 82, 254).—PbA" (dried at 100°). White powder, al. sol. water, v. sol. KOHAq and HNO₂.—Pb₂OA";: sticky pp., got by addifig lead subcoetate to sodium succinates.—Pb₂OA"; (dried at 200°): white powder.—ZnA" (dried at 200°). Crystalline powder.—ZnA" (dried at 200°). Crystalline powder.—ZnA"3NH₄. (Lutschak, B. 5, 30).—CdA".—(UVO)A" aq.—A(UVO)A" aq.—R(UVO)A" aq.—Na(UVO)A" aq.—Ra,A". White amorphous pp.—Quinine salt (C₂, H₄, N₂O₂, H₄A" aq. Prisms

8. '11 at 10° (Hesse, A. 135, 831).— Cinchonine salt $(C_{2s}H_{2s}N_{2}O)_{2}H_{4}A''$ aq. Thick crystals (Hesse, A. 122, 226).— Cinchonidine salt $(C_{2s}H_{2s}N_{2}O)_{2}H_{4}A''$ 6aq. Silky prisms. S. '4 at 10° (Hesse, As 135, 342).— Urea salt $(CON_{2}H_{1})_{2}H_{4}A''$. Six-sided monoclinic prisms; a:b:c=1:483:1:1:365; $\beta=83^{\circ}$ 28' (Lischmidt, Sits. W. 52, ii. 238).— Ethylene-diamine salt $C_{2}H_{1}(NH_{2})_{2}H_{2}A''$. [182°]. Thick white prisms, v. sol. water, insol. ether (Mason, C. J. 55, 10).— Benzylamine salts $(C,H,NH_{2})_{2}H_{2}A''$. [145°]. Thin plates, sol. alcohol (Werner, C. J. 55, 628).— $(C,H,NH_{2})H_{2}A''$. [117°]. Rectangular prisms (containing aq), v. sol. water.

(containing ad, v. sol. water.

Methyl ether Me_A". [19°]. (195° cor.).
S.G. 2º 1·1209 (Emery, B. 22, 3185); ½ 1·1261;
½ 1·0383 (Perkin, C. J. 45, 516). M.M. 6·232
at 18·2°. S.V. 159·7 (Lossen, A. 254, 64). H.C.
(solid) 703,600. H.C. (liquid) 708,500. H.F.
(solid) 205,400 (Stohmann, J. pr. [2] 40, 353).
Formed from succinic acid, MeOH, and gaseous
HCl (Fehling, A. 49, 195). Formed also from
succinyl chloride and NaOMe in ether, and from
Ag,A" and MeI. Crystalline, sol. alcohol.

Methylethylether MeEth". (208° cor.).
C.G. 2 1.093. S.V. 184.6. Formed by the action of Ethagh" on MeI (Köhler, A. 221, 88). On saponification by baryta it yields H_Ah", HMeh", and HEth" (Lossen a. Köhler, A. 262, 200).

Mono-ethyl ether HEth". Formed by

Mono-ethyl ether HEth". Formed by boiling succinic anhydride with alcohol (Heintz, J. 1859, 280). Syrup, miscible with water, alcohol and ether.—AgEth": amorphous, sl. sol. water.—The salt NaEth": amorphous, sl. sol. water.—The salt NaEth" is converted by POCl. into CO2Et.C.H., COCl (144° at 90 mm.), which is split up by distillation into EtCl and succinic anhydride, and is converted by phenyl hydrazine into CO2Et.C.H., CO.NH.NHPh [107°], crystallising in white needles, itself converted into O(CO.C.H., CO.N.H.Ph), [137°] by successive treatment with HOH and HCl (Michaelis a. Hermans, B. 25, 2748). The salt NaEth" is converted by a-chloro-propionic ether into CO2Et.C.H., CO.CHMe.CO2Et (280°) S.G. 2 1-119, which is split up by boiling with baryta water into succinic and lactic acids (Wurtz a. Friedel, J. 1861, 378).

Ethylether Et.A". (216:5° cor.). S.G \(\frac{1}{2} \) 10465; \(\frac{2}{35} \) 10383. M.M. 8:380 at 17:8° (Perkin). S.V. 209*4. Formed by boiling succinic acid (20 pts.) with alcohol (3 pts.) and H.SO. (1 pt.) (Eghis, B. 6, 1178; cf. D'Arcet, A. Ch. [2] 58, 291). It is also produced by heating C.H.Br. in alcohol with potassium succinate in sealed tubes (Davidoff, Bl. [2] 46, 818; 19, 406). Oil. Converted by Na into the dihydride of dioxyterephthalic ether. Not attacked by hydroxylamine (Jeaurenaud, B. 22, 1273). Succinic ether (40 g.) treated with cyanamide (20 g.) and an alcoholic solution of K (18 g.) for 5 hours with inverted condenser yields C.H.(CONKCy), and C.H.(CO.KCy). These bodies may be converted by AgNO₃ into Ag salts, which may be separated by HNO₃, in which silver 'succincyanamate' dissolves, while silver 'succinyldicyan-di-amide' is insoluble. The Ag salts may then be suspended in alcohol and decomposed by H.S (Möller, J. pr. [2] 22, 214). Succinyl di-cyan-di-amide C.H.(OO.NHOy), [105*] crystallies in monoollinic pyramids (containing 2aq), decomposed by warm water into succining 2aq), decomposed by warm water into succining 2aq), decomposed by warm water into succining 2aq), decomposed

seid and eyanamide. It may also be prepared acid and cyanamids. It may also be prepared by the action of NaNH.Cy on succinyl chloride, and by warming O₂H₄(CO)₂NOy with cyanamide. The salt C₂H₄(CO.NAgOy)₂†aq crystallises in plates, sol. NH₂Aq.—Et₄A"5TiCl₄ (Demarçay, C. R. 70, 1414).—Et₄A"2TiCl₄.—Et₄A"TiCl₄.

Ethyl propyl ether EtPrA". (231°).

S.G. § 1.0387. S.V. 230.2 (Wiens, A. 253, 300).

Yields, on saponification by baryta, salts of EtHA", PrHA", and H.A" (Lossen a. Köhler.

A. 262, 201).

A. 202, 201).

Ethyl butyl ether Et(C,H₀)A" (247°).

S.G. § 1.0218. S.V. 255.9 (W.).

Ethyl heptyl ether Et(C,H₁₅)A".

(291.4°). S.G. § 9850. S.V. 332.9 (W.).

n-Propyl ether Pr,A" (247.1°). (Wiens, A. 253, 300); (250.8°) (Perkin, C. J. 53, 561). S.G. $\frac{6}{0}$ 1·0189 (W.); $\frac{1}{2}$ 1·0157; $\frac{15}{13}$ 1·0062; $\frac{25}{23}$ 9986 (P.). S.V. 257·8. Formed by passing HCl into succinic acid in propyl alcohol.

Isopropyl ether Pr.A". (228°). S.G. 2

1.009 (Silva, A. 154, 255).

Propyl butyl ether Pr(C,H,)A". (258.7°). S.G. \(\frac{1}{6}\) 10166. S.V. 277-8 (Weins, A. 253, 300). Isobutyl ether (PrCH₂)₂A". (265° cor.). S.G. \(\frac{1}{15}\) 9737; \(\frac{25}{35}\) 9667. M.M. 12·707 at 14·5° (Perkin, C. J. 45, 519).

Isoamyl ether (C₂H₁₁)₂A". (290° cor. at 728 mm.). S.G. 13 961. Formed from Ag₂A" and isoamyl bromide (Del Zanna a. Guareschi, Atti | Roal Instit. Veneto [5] 6; B. 12, 1609), | Heptyl ether (C,H₁)₂A" (350°). | 8 9519. S.V. 459·6 (Wiens).

§ 9519. S.V. 4596 (Wiens).

Cetyl ether (C₁₆H₃₁)₂A". [58°]. Formed by neating the acid with cetyl alcohol (Tütscheff, Rep. Chim. pure, 2, 463). Plates, sl. sol. alcohol. v. sol. ether.

Ethylene ether C2H4A". [c. 90°]. By heating succinic acid with glycol at 170° there is formed crystalline (CO₂H.C₂H₁,CO₂)₂C₂H₄ melting below 100°, which at 300° yields C₂H₄A" (Lourenço, A. 115, 358). Crystalline, insol. water and ether,

sol. hot alcohol. Decomposed by distillation.

Di-phenyl ether C₂H₄(CO₂Ph)₂. [119°]. (330°). Formed from succinic acid, phenol and POCl, (Rasiński, J. pr. [2] 26, 63). Got also from succinyl chloride and phenol (Weselsky, B. 2, 519). Completely decomposed by slowly heating (Anschütz, C. J. 47, 898). NaSEt gives di-thiosuccinic ether. Pearly plates (from alcohol).

Di-benzyl ether (CH,Ph) A". [42°]. Formed from Ag2A" and benzyl bromide (Zanna a.

Guareschi, G. 11, 255). Laminæ.

Chloride C_2H_4 (CO.Cl)₂ or $C_2H_4 < \stackrel{CCl}{CO} > 0$. Mol. w. 155. (190°-200°). S.G. 1.39. Formed from succinic anhydride and PCl, (Gerhardt a. Chiozza, A. 87, 293).

Preparation.—Succinic acid is heated with PCI, for two days with an inverted condenser in an oil bath. The POCl, is distilled off (below 120°) and the residue shaken with benzoline that has been dried over lime. The benzoline dissolves the rest of the POCl, and the succinyl chloride separates as a lower layer. The operation is repeated until the oil no longer forms phosphoric acid when mixed with water (H. Möller, J. pr. [2] 22, 208).

Properties.—Solidifies at 0°.

Reactions.-1. Reduced to butyrolactone by sodium amalgam (8 p.c. Na) acting upon its

ethereal solution mixed with glacial acetic acid. -2. Bensens and aluminium chloride give C₂H₄<CO^{Ph₂}>O [90°], C₂H₄(CO.C₆H₈)₂ [184°], and a little \$\beta\$-benzoyl-propionic acid (Auger, A. Ch. [6] 22, 312; Bl. [2] 49, 345).-8. ZnEt. gives $C_2H_4 < \stackrel{CEt_2}{CO} > 0$.—4. Na₂S gives succinyl sulphide.-5. PCl, at 230° gives off HCl and the product, after treatment with water, contains C4Cl6O (199°-215°) which solidifies below 0°. Hot conc. H2SO, dissolves C,Cl,O and the product, diluted with water, yields on evaporation hygroscopic crystals, which on sublimation give non-hygroscopic plates of C.Cl.O. [120°] (Kauder, J. pr. [2] 28, 191). Di-chloro-maleic chloride is also a product of the action of PCl, on succinyl chloride .- 6. Chlorine passed into boiling succinyl chloride forms chlorides of fumaric, chlorocinyl chloride forms chlorides of lumaric, chloro-fumaric, and di-chloro-maleïa acids (Kauder, J. pr. [2] 31, 24).—7. C₆H₂,SO₂NBzAg forms C₂H₁(CO.NBz.SO₂C₆H₃)₂ [146°] (G. a. C.).— 8. Phenyl-hydrazine forms the compound C₂H₁(CO.NH.NHPh)₂ [218°] (Freund, B. 21, 2462; Fischer, B. 22, 2728), whence phospene produces C2H4(CO.N2Ph:CO)2[225°]. Sodium phenyl. hydrazine in benzene forms $C_2H_4 < \stackrel{\circ}{CO.NPh}$ [199°], which gives $C_2H_4 < \frac{\text{CO.NPh}}{\text{CO.NAc}}$ [179°] (Michaelis a. Hermans, B. 25, 2751).-9. Cyanamide in ethereal solution forms, on warming, succin-cyanimide C.H.(CO),NCy [138°] crystal-

C₂H₁(CO.NH.CO.NH₂)₂, a powder, v. sl. sol. hot water (Conrad, J. pr. [2] 9, 301). Anhydride C.H. CO O. Mol. w. 100. [119°]. (261°) (Krafft a. Noerdlinger, B. 22, 816). Formation.—1. By rapidly boiling succinic acid. 2. By distilling the acid with P.O. (D'Arcet, A. Ch. [2] 58, 282), with PCl, (Gerhardt a. Chiozza, C. R. 36, 1050), or with BzCl (Kraut, 1070). A. 137, 254).—3. By warming succinyl chloride with dry oxalic acid (Anschütz, A. 226, 16) .-4. By heating succinic acid (100 g.) with POCL (65 g.) at 120° (Volhard, A. 242, 150).—5. By distilling succinyl chloride (180 g.) with succinic acid (137 g.), and crystallising from alcohol (H. Möller, J. pr. [2] 22, 194).—6. By the action of dry Pb(NO₃)₂ (also nitrates of other heavy

lising from alcohol in plates (Möller, J. pr [2] 22, 207).—10. Cyano-acctic ether in Et.O at 100° forms C₂H₄:C₂O₂:CCy.CO₂Et [126°] (Muller, C. R. 112, 1140).—11. Urea at 65° forms the compound

Properties.— Long trimetric needles (from alcohol); a:b:c = 595:1:462 (Bodewig, B. 14, 2788). Sl. sol. water, v. sl. sol. ether. Converted by dry NH, into succinimide. Slowly converted by boiling alcohol into succinic ether. Phenylhydrazine reacts in alcoholic solution, forming CO,H.C,H,.CO.NH.NHPh [120°], converted by heat into C₂H₄<CO>N.NHPh [155°] (Auger,

metals) upon succinyl chloride; PbCl, is pro-

duced, and N2O4 and oxygen evolved; yield c

60 p.c. of theoretical (Lachowicz, B. 18, 2990).

A. Ch. [6] 22, 839; cf. this vol. p. 45) or [158] (Michaelis, B. 25, 2750). Potassium cyanamide forms 'succincyanamic' acid, the compound CO.H.C.H,.CO.NHCy [128°], which is v. e. sol. water, v. sol. alcohol and other, is split up by

dilute soids into succinic soid and cyanamide, and yields the following six salts Na, A" 5aq, K, A" aq, CaA" 4aq, BaA" 2aq, AgHA", and Ag, A" (Möller, J. pr. [2] 22, 193). Urea heated with succinic anhydride at 125° forms succinuric acid CO.H.C.H..CO.NH.CO.NH. [205°] (Pike, B. 6,

Nitrile C₂H.*(CN)₂. Ethylene cyanide. Mol. w. 80. [55°]. (147° at 10 mm.) (F.); (185° at 60 mm.) (Biltz, B. 25, 2541). H.C.p. 546,100. H.F. (from diamond) - 32,000 (Berthelot a. Petit, C. R. 108, 1217). Formed by boiling ethylene bromide (300 g.) with alcohol (500 g.) and KCy (200 g.) for two hours with inverted condenser (Maxwell Simpson, Pr. 10, 574; Geuther, A. 120, 268; Fauconnier, Bl. [2] 50, 214; Nevolé a. Tscherniak, C. R. 86, 1411). Amorphous, sometimes crystalline, solid, v. sol. water, alcohol, and chloroform; sl. sol. ether. Decomposed by distillation under atmospheric pressure. Converted into succinic acid by boiling alcoholic potash. Aniline hydrochloride at 200° reacts, forming di-phenyl-succinimidine C₂H₄ C(NH) NPh (Blochmann, B. 20, 1856). -C₂H₄Cy₂4AgNO₃: tables, sol. water and alcohol, insol. ether.

Amide-nitrile CN.C.H,.CO.NH,. Formed by heating the nitrile with alcoholic potash at 110° (Drouin, C. R. 108, 675). Crystals, sl. sol. Slowly decomposes at alcohol, insol. ether. 210°-220°.

Amide C.H. (CO.NH2)2. Succinamide. Mol. w. 116. [243°]. S. 625 at 9° (Henry, C. R. 100, 943); 11 at 100° (F.). Formed by the action of aqueous NH, on the ether and on the chloride (D'Arcet, A. 16, 215; Fehling, A. 49, 196). Formed also by warming succinimide with alcoholic NH₃ (Menschutkin, A. 162, 165, 187). Needles, insol. ether and alcohol. Decomposed at 200° into NH, and succinimide or by saturating at -15° with gaseous NH3, and heating to 150° in sealed tubes (Roubtzoff, Bl. [2] 45, 250) .-HgC,H₆N₂O₂1¹₂aq. White powder, deposited on cooling from a solution of HgO in hot aqueous succinamide.

Iso-amide $C_2H_4 < \frac{C(NH_2)_2}{CO} > 0$. [6. 95°].

Formed to the extent of 8 p.c. in the preparation of the amide from succinyl chloride and NH3Aq (Auger, A. Ch. [6] 22, 312). Hygroscopic mass. Its aqueous solution gives with AgNO, a pp. of

C₂H₄(CO)₂NAg.

Methylamide C₂H₄(CO.NHMe)₂. Plates (Wallach a. Kamenski, B. 14, 170).

Dimethylamide C.H. (CO.NMe.). [81°]. Formed from succinyl chloride and NHMe, in ether (Franchimont, R. T. C. 4, 202). Crystals (from ether), v. sol. water.

Benzyl-di-amide C,H4(CONH2)(CONHCH,Ph). [189°]. Formed from the benzylimide and ammonia at 100° (Werner, C. J. 55, 633). Minute prisms, sl. sol. ether and hot benzene. Yields the benzylimide when heated.

Di-bensyl-diamide C.H.(CO.NHCH.Ph). [206°]. Formed from succinic ether and benzylamine in alcohol. Thin plates, not decomposed by boiling NaOHAq.

Anilide C₂H₄(CO.NHPh)₂. [227°]. Formed by boiling succinic acid with aniline (Laurent a.

Gerhardt, A. Ch. [8] 24, 179; A. 68, 27; Menschutkin, A. 162, 187). Needles (from alcohol), insol. water. Not affected by boiling alcoholic potash or by nitrous acid. Gives the phenylimide on distillation. Cold fuming HNO₈ converts it into C.H. (CO.NHC₈H. (NO₂)[1:41)₈ [260°] (Hübner, A. 209, 877). Benzoic aldehyde at 180° forms succinic phenylimide and benzyl-

idene-aniline (Schiff, A. 148, 338).

Amide-anilide CO(NH₂).C₂H₄.CONHPh. [181°]. Formed by heating the phenylimide with alcoholic NH₃ at 100° (Menschutkin, A. 162, 182). Broad needles (from water), sl. sol. hot alcohol. Alkaline KOBr followed by heating werff a. Van Dorp, R. T. C. 9, 41).

Di-(a)-naphthyl-di-amide

C₂H₄(CO.NHC₁₀H₁)₂ [285°]. Needles (from HOAo). Converted by fuming nitric acid into C₂H₄(CO.NH.C₁₀H₂(NO₂)₂)₂, [225°], and C₂H₄(GO.NH.C₁₀H₃(NO₂)₄)₂ [256°]. Tetra-phenyl-di-amide

C2H4(CO.NPh2)2. [234°] (Piutti, G. 14, 467).

Needles (from alcohol).

o-Tolyl-diamide C₂H₄(CONH₂).CO.NHC₇H₇. [160°]. Formed by heating the o-tolylimide with alcoholic NH₃ at 100°. Plates.

Di-o-tolyl-diamide C2H1(CO.NHC,H7)2 [100°]. White needles (Bechi, \hat{B} . 12, 25, 321). V. sl. sol. water, m. sol. alcohol.

 $p \cdot Tolyl \cdot di \cdot amide$ $C_2H_1(CONH_2).CONHC_1H_7$. [148°]. Formed by heating the p-tolylimide with alcoholic NH3.

Di-p-tolyl-diamide C.H.(CO.NHC,H.).
[256°]. Plates (from alcohol), sl. sol. hot water
(Bechi, B. 12, 323; Hübner, A. 209, 380). Yields on nitration C2H1(CO.NHC,H8.NO2)2 [217°] and C2H4(CO.NH.C7H5(NO2)2)2

(β)-Naphthalide C2H1(CO.NHC,H1)2. [266°] (Bischoff a. Reebe, B. 25, 3267). Got by heating succinic acid (10 g.) with (β) -naphthylamine (24 g.). Insol. ordinary solvents, sol. H,SO.

Amic acid CO₂H.C₂H₁.CO.NH₂. Succinamic acid. [157°]. Formed by warming succinimide with an equivalent quantity of baryta water (Teuchert, A. 134, 136) or milk of lime (Menschutkin, A. 162, 175). Formed also from nitrosoglutaric acid by heating alone or with Ac,O (Serda a. Wiedemann, B. 23, 3284; Wolff, A. 260, 114). Needles, m. sol. water, insol. alcohol. Decomposed at 200° into water and succinimide. Boiling water forms acid ammonium succinate.

Salts.-KA': very hygroscopic mass (Landsberg, A. 215, 201).—BaA'₂: needles, v. sol. water.—CaA'₃.—MgA'₂ 8aq : trimetric crystals.—MgA'₂ 6aq.—CdA'₂ aq: prisms.—CuA'₂.—PbA'₃. Concentric needles, v. sol. water.—MnA'₂ 5aq.— ZnA'₂. — AgA': monoclinic crystals, v. sol. NH₃Aq.

Ethyl-amic acid CO2H.C2H4.CONHEt. Formed by warming the ethylimide with baryta water (Menschutkin, A. 182, 92). - Ead's: orystals, v. sol. water,

Ethylens-di-amic acid C,oH,sN2O, i.e. C.H.(NH.OO.C.H., CO.H.). Ethylene-disuccin-amic acid. [185]. Formed by boiling the di-imide with baryta (Mason, C. J. 55, 13). Large plates, v. sol. hot water. Does not yield an oxim or a phenyl-hydrazide.—CaA" 8aq: prisms.
—Ag₂A": white amorphous powder.

Bensylamic acid

CO.H.C.H. CO.NHC.H.

[139°]. Formed by boiling the benzyl-imide (2 mols.) with aqueous barium hydroxide (1 mol.) (Werner, C. J. 55, 631). Flat prisms, m. sol. hot water, v. sl. sol. ether.

Phenylamic acid CO2H.C2H4.CO.NHPh. Succinantic acid. [149°]. Formed by boiling the phenylimide with NH₂Aq (Laurent a. Gerhardt, A. Ch. [3] 24, 179) or baryta (Menschutkin, A. 162, 176). Flat needles, v. sl. sol. cold water. Decomposed by heat into water and the phenylimide. Boiling alcoholic HCl forms succinic acid. — CaA', 4aq. — BaA', 3aq. — AgA': crystalline pp.

o-Tolyl-amic acid CO₂H.C₂H₄.CO.NHC₇H₇. [97°]. Got by boiling the o-tolylimide with baryta water (Bechi, B. 12, 322). White needles.—BaA'2 aq.

p-Tolyl-amic acid [157].—BaA', aq. (a)-Naphthyl-amic acid

CO,H.C,H,.CO.NHC,H,. [171°]. Formed by heating the (a)-naphthylimide with KOHAq (Pellizzari, A. 248, 158; G. 18, 323). Needles or plates (from alcohol), v. e. sol. HOAc and benzene

(B)-Naphthyl-amic acid [192°]. Crystals. Di-phenyl-amic acid

CO2H.C2H4.CONPh2. [119°]. Plates (Piutti, G. 14, 468).—AgA': pp.
Phenylene-di-amic acid

C₈H₄(NH.CO.C₂H₄.CO₂H)₂. Formed by heating phenylene-diamine with succinic acid at 200° (Biedermann, B. 9, 1668). Small crystals (from HOAc). Melts above 360°. Converted by KOHAq and MeI into C.H. NMe.O.CO crystallising in plates or tables (containing 1 aq)

(Griess, B. 18, 2410).

Imide CH₂CO NH. [126°] (Erlenmeyer, Z. [2] 5, 175). (288°). H.C. 439,000. H.F. 110,500 (Berthelot a. André, Bl. [3] 4, 229). Formed from succinic anhydride and dry NH₃ (D'Arcet, A. Ch. [2] 58, 294), and also by heating succinamide or ammonium succinate (Fehling, A. 49, 198; Laurent a. Gerhardt, Compt. Chim. 1849, 108; Menschutkin, A. 162, 165, 187; 182, 93). Large efflorescent crystals (containing aq) or octahedra (from acetone) (Bunge, A. Suppl. 7, 118), v. sol. water and alcohol, m. sol. ether. Not attacked by pure HNO_s (S.G. 1.53) (Franchimont, R. T. C. 6, 228). Converted by hot baryta water into succinamic acid, and finally into succinic acid. Alcoholic NH, at 100° forms succinamide. Yields pyrrole on distillation with zinc-dust. KOH (6 mols.) and KBrO (1 mol.), acting for two hours at 60°, form (β)-amidopropionic acid [196°] (Hoogewerff a. Van Dorp, R. T. C. 10, 4). Bromine forms bromo-succinimide [225°] and bromo-maleïmide [152°] (Kisielinski, Sits. W. [2] 74, 561; cf. Kusseroff, A. 252, 158). Chlorine at 160° forms chloro- and di-chloromalete imide. PCl, forms a compound melting You IV,

at 145°-148° (Bernthsen, B. 18, 1047). A solution of bleaching-powder added to a solution of succinimide containing excess of HOAc forms C₂H₄<CO>NCl [148°], which separates from benzene in large crystals, and is reconverted by acids and alkalis into succinimide (Bender, B. 19, 2273). Hydroxylamine at 65° forms NH(CO.C.H.,CO.NH.OH), [171°], crystallising in needles, v. e. sol. water, and yielding a picrate B'C₆H₂N₅O, [266°] (Garny, B. 24, 3434). Methyl cyanate forms C₂H₄ CO.NH₂ CO [149°], while EtNCO forms corresponding O,H10N2O, [950] (Menschutkin, A. 178, 204).

Salts.-KC,H,NO, 1/2 aq. Ppd. by adding alcoholic potash and ether to an alcoholic solution of succinimide (Landsberg, A. 215, 200).tion of succinimide (nandsberg, A. 210, 200).—

KA': needles. V. sol. water and alcohol.—

BaA', 2aq. — BaA', 2½aq. — MgA', 2aq. —

HgA', — NH, HgA'. — ClHgA'. — CyHgA'. —

Cu, A', (OH), 9aq. — Cu, A', (OH), 2aq. — AgA' ½aq.

Needles. Converted by iodine into IC, H, NO, crystallising in dimetric prisms; a:c=1: 873, melting, with evolution of I, at 135°. Silver succinimide is converted by succinyl chloride in ethereal solution into 'trisuccinamide' (C,H,O₂)₃N₂ [83°], crystallising from ether (Gerhardt a. Chiozza, A. 90, 108).—AgA'NH₃: crystalline.

Methylimide C₂H₄:C₂O₂:NMe. (234°). Formed by distilling methylamine succinate. Plates. Got also by the action of conc. H2SO4 on the oxim of \$\beta\$-acetyl-propionic acid (Rischbieth; Bredt a. Boeddinghous, A. 251,

Ethylimide C2H4:C2O2:NEt. [26°]. (234°). Formed by distilling acid ethylamine succinate (M.), and by adding alcoholic EtI to sodium succinimide (Landsberg, A. 215, 212). Long lancet-shaped crystals, v. sol. water, alcohol, and ether. Yields ethyl-pyrrole on distillation over zinc-dust.

Allylimide C.H.:C.O.:NC,H. (245°).
S.G. § 1:1543; ½ 1:1432. Formed by heating succinic acid with allyl thiocarbimide. Liquid, v. sol. water and alcohol.

Ethylene-imide (C,H,:C,O2:N),C,H, [251°]. (395°). Formed by heating succinic acid with the hydrate of ethylene-diamine at 180° (Mason, C. J. 55, 10). Prisms, sol. hot water, v. sl. sol. hot alcohol, insol. ether.

Propylene-imide (C₂H₄:C₂O₂:N)₂C₃H₆. [100°]. Formed from the anhydride and propylene-diamine (Strache, B. 21, 2360). Crystals (from benzene).

Phenylimide $C_2H_4:C_2O_2:NPh.$ cinanil. [156°] (L. a. G.; Kauder, J. pr. [2] 31, 17). [150°] (Hübner, A. 209, 373; Bischoff a. Nastvogel, B. 22, 1807) (above 300°). Formed by heating succinic acid with aniline, and crystallising the product from water and alcohol successively (Laurent a. Gerhardt, A. Ch. [8] 34, 179). Formed also by the action of PCl, on C2H,(CO.NHPh).CO2H in chloroform (Anschütz, 8. 21, 957). Needles, sl. sol. hot water. PCl. in presence of boiling POCl. forms the phenylimide of di-chloro-maleïc acid C. Cl.; C. 20; NPh. Alcoholic NH. forms C. H. (CONH.). CONHPh. Boiling lime water forms C. H. (CO. H.). CONHPh. Fuming HNO forms an o-nitro-derivative [156°]

and the p-nitro derivative [205°-208°]. The salt C.H.:C.O.:NC.H.:SO.Na is got by heating succinic acid with sodium amido-benzene p-sulphonate (Pellizzari, G. 18, 817).

Bensylimide C2H4:C2O2:NCH2Ph. Formed from benzyl chloride, succinimide, and alcoholic NaOH (Werner, C. J. 55, 629). Six-

sided prisms, sol. alcohol.

o-Tolylimide C₂H₄:C₂O₂:NC₆H₄Me. (345° uncor.). Formed by heating o-toluidine with succinic acid (Michael, B. 10, 579; Bechi, B. 12, 25, 321). Needles, v. sol. water.

p-Tolylimids. [150°]. (345°). Needles (from water), sl. sol. cold water. Yields on nitration C₂H₄:C₂O₂:NC₈H₃Me(NO₂)[1:4:2] (Hübner, A. 209, 378).

Tri-methyl-phenyl-imide C2H4:C2O2:NC H2Me2. Succinmesidil. ſ137°1. Formed by heating succinic acid with mesidine (Eisenberg, B. 15, 1018). Pearly plates, sol. alcohol and ether, sl. sol. water.

(a) - Naphthylimide C.H.; C,O.; NC, H, [153°]. Formed by heating succinic acid with (a)-naphthylamine (Hahnemann, B. 10, 1713; Hübner, A. 209, 381; Pellizzari, A. 248, 158). Needles, m. sol. alcohol. Yields a di-nitroderivative [250°]. The sulphonic acid C₂H₄:C₂O₂:NC₁₀H₆SO₃H, prepared from (α)-naphthylamine p-sulphonic acid, yields KA' 2aq (Pellizzari, G. 18, 321).

(β)-Naphthylimide. [180°]. Colourless needles, v. sol. alcohol. Converted by ΚΟΗΑq into CO2H.C2H4.CO.NHC10H7 [192°] (Pellizzari,

A. 248, 159).

Benzimidide C,H,:C,O,:NCPh:NH. [212°]. Formed from acetyl-succinic ether C10H16O5, benzamidine hydrochloride, and NaOHAq (Pinner, B. 22, 2620). Needles, sl. sol. cold acetone and ether, sol. alcohol.

References .- Amido-, Bromo-, Bromo-Amido-, CHLORO-, NITRO-, and OXY-SUCCINIC ACID and DI-IODO-SUCCINAMIC ACID.

Isosuccinic acid v. METHYL-MALONIC ACID.

SUCCINIC ALDEHYDE. Reduction of succinic anhydride, which might be expected to yield the aldehyde, forms instead the isomeric

y-oxy-butyric lactone.

Oxim C.H.(CH:NOH)₂. [173°]. Formed by heating pyrrole with hydroxylamine hydrochloride at 100° and, together with ethylamine, by the action of hydroxylamine on v-ethylpyrrole (Ciamician, B. 17, 533; 22, 1968; 23, 1788). Small white crystals (from alcohol). May be reduced to tetrametlylene-diamine

C.H. (CH.NH₂)₂ [28°]. Phenyl hydrazide C.H.(CH:N.HPh), [125°]. Formed by heating a solution of the oxim (1 pt.) in water (50 pts.) with phenyl hydrazine (5 pts.) dissolved in dilute HOAc (Ciamician, B. 22, 1974; 23, 1784). Small silky plates, v. sol. alcohol. Converted by cold conc. HClAq into a base C₂₀H_{.0}N, [185°], which crystallises from EtOAc in needles, v. sl. sol. alcohol, and gives a deep-blue colour with K2Cr2O, and H2SO.

Succinic semi-aldehyde. Nitrile

CN.CH, CH, CHO. B-Cyanopropionic aldehyde (77°). S.G. 15 89. Formed by heating AgCy (67 g) for ten hours (Chautard, A. Ch. [6] 16, 182). Oil, not solid at -20°, miscible

with alcohol and ether. Reduces Fehling's solution. Does not combine with NaHSO, or phenyl-hydrazine. Decomposed by hot alkalis and acids. Aniline at 350° forms the compound CH,Cy.CH(NHPh),

Succinimidine C.H, N. i.s.

 $C_2H_4 < C(NH) > NH$. Formed, as hydrochloride, together with NH,Cl, by the action of water on succinamidine (Pinner, B. 16, 362, 1657; 18, 2845).-B"HCl: long plates, v. sol. water, sl. sol. alcohol. Converted by acetoacetic ether into crystalline $C_8H_{11}N_3O_2$.— $B''(HNO_3)_2$ $\frac{1}{2}aq$: leaflets (Grabowski, A. 265, 168).— $AgC_1H_uN_3$: ppd. by adding ammoniacal AgNO, to a solution of the hydrochloride.

SUCCINIMIDO-ACETIC ETHER C,H,1NO. i.e. C2H4:C2O2:N.CH2.CO2Et. [67°]. Formed by heating succinimide with alcohol, NaOEt, and CH2Cl.CO2Et (Haller a. Arth, C. R. 105, 280). Needles, v. sol. water, alcohol, and ether. Alcoholic NaOEt forms gelatinous CaH10NaNO4

SUCCINIMIDO-ETHYL ETHER C8H16N2O2 i.e. C.H. (C(NH).OEt). The hydrochloride B"2HCl is prepared by passing gaseous HCl into an ethereal solution of ethylene cyanide (Pinner, B. 16, 359). It is v. sl. sol. alcohol and ether, and decomposed by water into succinic ether and NH Cl. With ammonia it gives $C_2H_1(C(NH).NH_2)_2$.

 $C_2H_4 < CO \longrightarrow NH.$ SUCCINIMIDOXIM

[197°]. Formed by heating ethylene cyanide with alcoholic hydroxylamine at 65° (Garny, B. 24, 3427). White crystals, sol. water. -B'HCl. [98°]. Needles.— $B'C_{6}H_{3}N_{3}O_{7}$. [212°].

Benzoyl derivative

 $C_2H_4 < CO$ NH. [184°]. Formed from the oxim, NaOH, and BzCl. White powder, sol. alcohol, sl. sol. ether.

SUCCINOPHENONE v. DI-PHENYL ETHYLENE

SUCCINOXYL-AMIDO-BENZOIC CARBOXY-PHENYL-SUCCINAMIC ACID.

SUCCINYL-AMIDO-BENZOIC ACID AMIDO-BENZOIC ACID.

SUCCINYL - SUCCINIC ACID v. DI-OXY-TEREPHTHALIC ACID DIHYDRIDE, vol. iii. p. 777.

SUCCISTERENE $C_{15}H_{10}$. [160°]. (above 300°). Occurs in the product of distillation of amber (Pelletier a. Walter, A. Ch. [3] 9, 96). Flat needles, nearly insol. cold alcohol, v. sl. sol. ether.

SUGAR, a term applied to the members of a group of carbohydrates in consequence of the property they possess of being sweet to the taste and of their relationship to the substance to which the term was originally given. The known natural members of this group are not very numerous. They are all easily soluble in water crystallisable, and diffusible. When solutions of them are heated with alkaline solutions of the more easily reducible metals, reduction takes place with precipitation of the lower oxides in some cases, and of the metals in others; some sugars, before exhibiting this property, require to be digested with dilute mineral acids. En zymes also convert some of the non-reducing members into reducing ones. With phenyl

hydrazine they yield phenylhydrazides and phenylosazones. Oxidising agents easily convert them into soids, and reducing agents into alcohols. Some of them undergo fermentation when submitted to the action of beer yeast, i.e. they are decomposed into alcohol, CO2, &c. They yield solutions which are optically active, those of some rotating the plane of polarisation to the right, of others to the left. They give colour reactions with aromatic acids and phenols.

The group may be divided into two classes: (1) those which, when digested with dilute acids. do not yield any other sugar or sugars-the sugars of this class are distinguished by the termination -ose; (2) those which, when diges-ted with dilute acids, do yield some other sugar or sugars-these sugars are distinguished by the termination -on. They are designated according to the number of carbon atoms they contain: thus, pentose containing C, hexose containing Co, &c., and di-penton containing C10, di-hexon containing C12, &c.

The members of the -osc class are: Triose C₃H₆O₃, glycerose

Tetroses C₄H₈O₄, erythrose C₄H₂(C₆H₃)O₄, phenyltetrose

Pentoses C, H, O, arabinose

ribose xylose

CaH, (CH,)Os, rhamnose (methyl pentose)

fucose (ditto)

Hexoses C₈H₁₂O₆, d- l- and i-1 glucose (dglucose = dextrose) $d \cdot l \cdot \text{ and } i \cdot \text{mannose}$

d- l- and i-gulose

d- l- and i-fructose (d-

fructose = lævulose) d- l- and i-galactose

sorbose (sorbinose)

formose lokaose

B-acrose

C.H.1(CH.)O., rhamnohexose (methyl hexose).

Heptoses C, H, O, mannoheptose

a- and β -glucoheptose

galaheptoso

fructoheptose

digitalose

C,H,s(CH3)O, rhamnoheptose (methyl heptose).

Octoses C₈H₁₈O₈, mannoctose

a- and B-glucoctose Nonoses C_pH₁₉O_p, mannononose

glucononose The members of the -on group are:

Di-penton C10H18On, arabinon

Di-hexon C₁₂H₂₂O₁₁, cane-sugar (saccharon) milk sugar, lactose

(lacton) (di-glucon. maltose

amylon)

iso-maltose

melibiose

trehalose

cyclamose

para-saccharose tewfikose (tewfikon)

id, hand i. Fischer's notation, see p. 583,

Tri-hexon C₁₈H₃₂O₁₆, raffinose Hex-hexon C_{3e}H_{e2}O₃₁, gentianose stachyose

Occurrence.—Some of these sugars have been obtained by synthesis, others are products of the action of dilute acids or ferments on more complicated bodies, and others occur naturally. The most important source of the latter is the vegetable kingdom. Little, if anything, is known concerning the formation of the sugars in nature; it is very probable that they are intermediate products of assimilation between CO₂ and H₂O₄ and starch, inulin, cellulose, and such bodies. For an account of the various theories, see textbooks of vegetable and animal physiology. The sugars found in animals are most probably of vegetable origin.

Determination .- Owing to the fact that the sugars possess many properties in common, the presence of a particular sugar can only be definitely proved by its isolation in the pure state. and a determination of its optical activity, reducing power, and other definite distinguishing

properties (v. end of art.).

Molecular Weight.—Until quite recently none of the accepted methods for determining molecular weights were applicable to the sugars. At the present time there are several, chief among which are the physical methods of Raoult (A. Ch. [5] 28, 133; [6] 2, 66-124; [6] 4, 401; [6] 8, 289 a. 317), and De Vries, which are of general application, and the various chemical ones which are of special application. By Raoult's method Brown and Morris (C. J. 1888, 610; 1889, 462), Tollens and Mayer (B.21, 1566), and Tollens, Mayer, and Wheeler (B. 21, 3508), Ekstrand and Mauzelius (Vetensk. Akad. für Handl. 1889. 157), and O'Sullivan (C. J. 1890. 62) have determined the molecular weight of xylose and arabinose to be 150, corresponding to a formula C, H10O; of dextrose, lævulose, galactose to be 180, corresponding to a formula CaH12O6; of arabinon to be 282, corresponding to a formula C10H18O9; of cane sugar, maltose, lactose to be 342, corresponding to a formula $C_{12}H_{22}O_{11}$; and of raffinose to be 504, corresponding to a formula $C_{18}H_{32}O_{16}$. These numbers have been confirmed in the case of the simpler sugars by various chemical methods (see succeeding paragraphs). In the case of arabinose it was first shown to be C,H,O, by Kiliani (B. 20, 339) by the analysis of some of its compounds, its formula previously having been considered to be C.H,2O.

Synthesis.-The first step towards the synthesis of the sugars was made by Butlerow (A. 120, 295; C. R. 53, 145). He obtained a sweet syrup, having the common characteristics of the sugars, by adding lime-water to a hot solution of di-oxymethylene; the product he called methylenitan, and considered its formula to be C, H14Oe. The next step was made by Loew (J. pr. 33, 321), who, having discovered a method for the preparation of formaldehyde (CH,O) in quantity, investigated its condensation by lime-water. He obtained a sweet syrup, which he called formose, and considered it to have a formula C.H,2O. Neither methylenitan nor formose fermented with yeast (see also Tollens, B. 19, 2133). Fischer (B. 21, 989) finds these products to be a mixture of various saccharine bodies. the chief which is a sugar, formose $C_0H_{12}O_4$, yielding an osazone $C_1H_{22}N_1O_4$, m.p. 144°. Another sugar is present in smaller quantities in the condensation products of formaldehyde. It yields an osazone greatly resembling glucosazone, which has been identified with a acrosazone. Later, Loew (B. 22, 475), by the condensation of formaldehyde with lead oxide and magnesis, obtained a sugar which is fermentable. Loew called this methose, but Fischer has shown it to be identical with a acrose.

Acrose was obtained by Fischer (B.20, 1093 and 2566) by acting on acrolein bromide with bases $2C_sH_oOBr_2 + 2Ba(OH)_2 = C_sH_uO_s + 2BaBr_2$. Two isomeric sugars, a-acrose and β -acrose, are

thus produced.

Glycerose yields these two sugars by the action of alkalis. (Glycerose is a sugar C₂H₀O₂, obtained by the action of bromine and soda on glycerol and other methods by Van Deen, J. 1863. 501; Grimaux, C. R. 104, 1276; and Fischer a. Tafel, B. 20, 1088 and 3385; 22, 106. It is probably a mixture of the aldehyde and ketone of glycerol.) The formation of a-acrose from glycerose may be represented CH_(OH).CH(OH).COH+CH_OH-CO.CH_OH=CH_OH.CH(OH).CH(OH).CH(OH).CH(OH).CO.CH_OH. The sugars can only be separated from the products thus obtained as osazones; a-acrosazone is identical with glucosazone in every way except in its action on polarised light.

a-acrosazone

CH₂.OH(CH.OH)₃C—CH.N.NHC₆H₅

й.NH.C₄H.

acted on by furning hydrochloric acid, is converted CH, OH. (CH.OH), CO.COH, into a-acrosone which, when reduced by zinc and acetic acid, , yields a sugar CH2.OH(CH.OH)3.CO.CH2OH, in the form of a sweet syrup; it ferments with yeast, yields lævulinic acid when heated with hydrochloric acid, and is reduced by sodiumamalgam to a hexahydric alcohol α-acritol, which resembles mannitol in every way except that it is optically inactive. By these various reactions so much is lost that from 1 kilo. glycerol only 0.2 g. acritol is obtained. Further, all the bodies obtained in the processes were optically inactive. More knowledge was necessary before the natural sugars could be synthesised. At this stage a new light was thrown on the subject by an observation of Fischer (B. 23, 870) that arabinose carboxylic acid and mannonic acid were identical in every way except that their optical activities, although equal, were opposite in sign, and that they combined to form an optically inactive acid. These three acids were reduced by sodium-amalgam to three sugars resembling one another in all respects except that one of them had a right-handed optical activity, the other an equal but lefthanded one, while the third was optically inactive. They are named l-mannose, i-mannose, and d-mannose; by further reduction they yielded the corresponding hexahydric alcohols I-mannitol, i-mannitol, and d-mannitol.

The sugar obtained from a-acrosazone as

2, 4, and d are very unsatisfactory, and somewhat misleading: but as Fischer has introduced them we must let them stand. A little study will make their meaning dess. above described is identical with lavulose except that it is inactive. If, then, we can decompose this lavulose into d-lavulose and l-lavulose, the synthesis of the natural sugar will be accomplished. This Fischer has done (B. 23, 870). If i-lavulose be submitted to the action of yeast, the lavo- constituent ferments and the residue is dextrorotatory. This is l-lavulose; it is not the natural sugar: that belongs to the d-group, and was destroyed by the ferment.

To obtain the natural sugar from the inactive synthetic one, Fischer proceeded as follows:—i-mannitol, i.e. a-acritol, is oxidised by nitric acid to i-mannose, and this further by bromine-water to i-mannonic acid. By fractional crystallisation of the strychnine or morphine salts it can be mesotomised, the result being d-and l-mannonic salts, which, on being freed from the base, yield by reduction the corresponding mannoses and mannitols. These, by means of the osazones, can be converted into the corresponding lawuloses (see Dextrosazone).

Dextrose and mannose both yield the same osazone; the difference in their constitution must therefore be caused by the position of the group marked with a * in the formula

СН, (ОН).СН(ОН).СЦ(ОН).СН(ОН).•СН(ОН).СОН. Fischer (B. 23, 799 a. 2611) found that by heating gluconic acid with quinoline, part was converted into mannonic acid and part unaltered; and also that mannonic acid, treated in the same way, yielded some gluconic acid. Dextrose may then be obtained by reducing the gluconic acid thus The corresponding reaction with obtained. I-mannonic acid does not take place easily, if at all, but 1-gluconic acid is produced simultaneously with arabinose carboxylic acid (l-mannonic acid) by Kiliani's mode of preparation (see Arabinose). From l-gluconic acid, by reduction, l-glucose, the optical isomer of dextrose, is obtained. The table on next page gives a concise view of the synthesis of dextrose, lævulose, and mannose.

Another sugar, gulose, stereoisomeric with glucose, has been obtained by Fischer (B. 23, 93; 24, 521) by the reduction of saccharic acid, the d-, l- and i- modifications being obtained by the reduction of d-, l- and i- saccharic acids. As these are the products of the oxidation of d- l- and i- glucose, the synthesis of gulose is complete.

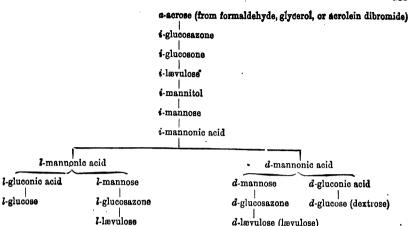

Galactose has not been synthesised up to the present (June 1893), but by the reduction of mucic acid Fischer and Hertz (B. 25, 1247) have obtained i-galactonic acid and i-galactose; i-galactonic acid, by the fractional crystallisation of its strychnine salt, may be mesotomised into d- and I-galactonic acids from which d-and I-galactose are obtained; d-galactose is identical with ordinary galactose.

Arabinose has not been directly synthesised, but its relationship to the synthetical sugars is shown by the fact that the two acids obtained from arabinose by the nitrile reaction are I-mannonic acid and I-gluconic acid (Fischer, B. 23,

2611; 24, 539).

Of zylose the same must be said; but by the nitrile reaction it yields l-gulonic acid (Fischer a. Stahel, B. 24, 528).

Arabonic acid, when heated with quincline, is partly changed into its stereoisomeride ribonic

acid, just as gluconic acid yields gulonic acid; ribonic acid, by reduction, yields the stereoisomeride of arabinose, which it is proposed to call ribose.

The synthetical passage from an -ose sugar to an -on one is said to be accomplished for lactose (lacton) and cane sugar (saccharon) as well as for maltose (amylon).

Lacton. A mixture of dextrose and galactose, is acted on by acetic anhydride, and the resulting products, carefully saponified with alkali, yield lacton (Demole, C. R. 69, 481). This has been contradicted by Berthelot (Bl. [2] 34, 82) and by Herzfeld (4. 220, 219).

Sucron. A body having a dextrorotatory power, and by inversion becoming lævorotatory, was obtained by acting on aceto-chlorhydrose (a derivative of dextrose) with an alcoholic solution of lævulose in the presence of barium carbonate. Another body which was lævorotatory, and became less lævorotatory on inversion, was obtained by acting on aceto-chlorhydrose by sodium lævulosate (Colley a. Vakovitch, Bl. [2] 34, 826).

Isomaltose has been prepared by Fischer (B. 23, 3687) by the action of HCl on dextrose. Dilute acids again hydrolyse it to dextrose, the same product as is yielded by maltose.

Phenyl-tetrose has been prepared synthetically from cinnamaldehyde cyanhydrin; this, by the action of bromine, yielding phenyl-dibromovay-butyronitrile CH.Ph.Br.CH.Br.CH.OH.CN, which, when heated with hydrochloric acid, yields phenyl-bromo-di-oxy-butyrolactone, from which the corresponding acid OH.CH.Ph.CHBr.CH.OH.COOH is easily obtained, and which on reduction yields the sugar OH.CH.Ph.CH(OH).CH(OH).COH.

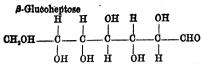

It will not be out of place here to indicate what has been done in the way of converting a sugar into one containing a carbon atom more. To do this, Fischer (B. 22, 2204; 23, 370, 799, 980, 2226, and 3102; Ann. 270, 64) made use of the well-known reaction for proceeding from one alcohol to its next higher homologue by means of the nitrile. Now, in this reaction, where an asymmetric carbon atom is added to the molecule,

d-lævulose (lævulose) Van't Hoff has predicted that two isomeric bodies will be formed which will differ by the arrangement of the groups round the new carbon atoms. Fischer (Ann. 270, 64) has shown that this is so in the case of the glucose homologues, the two acids obtained from glucose being a- and B-glucoheptonic acids; a-glucoheptonic acid is always the principal product of the reaction, and is identical with the dextrose carboxylic acid described by Kiliani (see Dextrose). When the reaction takes place at 20°-25° hardly a trace of the β-acid is formed; but at 40° about 13 p.c. of the latter is obtained. By oxidation these acids yield two penta-oxy-pimelic acids, the α- acid being optically inactive, and by reduction the two sugars a- and β-glucoheptose are obtained.

a-Glucoheptose

separates from its aqueous solution in rhombic prisms, m.p. 180°-190°; they have a faintly sweet taste, dissolve in 10.5 pts. of water at 14°, and are easily soluble in hot water and sparingly in hot alcohol. Its solution is optically active. Freshly-prepared solutions show a slight bi-rotation; for a 10 p.c. solution, $[a]_{1200} = -19.7^{\circ}$. It does not ferment with yeast, but reduces Fehling It is oxidised by slightly less than dextrose. bromine to a-glucoheptonic acid. It yields a hydrazone C,H₁,O₈N₂HC₆H₅, very soluble in water, m.p. 170°, and also an osazone C,H₁,O₅(N₂HC₄H₅), forming yellow needles, m.p. 108° almost involvable in water and difficulty in 195°, almost insoluble in water and difficultly in hot alcohol. Treated with acetic anhydride and zinc chloride it yields a hexacetate, m.p. 156°, and with sodium acetate and acetic anhydride it yields dec-acetyl-diglucoheptose C14H16(C4H2O), O12 m.p. 131°-132°.

By reduction with sodium-amalgam, a-gluco-heptose yields a-glucoheptitol, which crystallises in delicate prisms, m.p. 127°-128°, is optically inactive, easily soluble in water and sparingly in alcohol. It yields a heptacetyl derivative C.H.(C.H.O),O.

is obtained by the reduction of β-glucoheptonic acid, it has not yet been obtained in a crystalline state, it forms a phenyl-hydrazide C,H₁,O_eN₂H.C_eH₃, crystallising from alcohol in slender needles, m.p. 192°; the osazone is identi-

cal with a-glucoheptosazone.

Just as dextrose yields two isomeric glucoheptonic acids, so a-glucoheptose yields two isomeric glucoctonic acids. The a-acid is the chief product, and the amount of \$\beta\$- acid formed varies with the temperature. a-Glucoctonic acid yields a lactone $C_8H_{14}O_8$, sparingly soluble in alcohol and readily in water, m.p. $145^{\circ}-147^{\circ}$ [a]_{D26°} = $-45^{\circ}9$; by reduction with sodium-amalgam it yields a-glucoctose C.H., Os. 2H.O, which crystallises in colourless needles, m.p. 93°. Its aqueous solutions are optically active and show bi-rotation, [a] page = -50.5° for the anhydrous sugar. It yields a phenyl hydrazone C,H₁₀O, (N, IIC,H₃), m.p. 190°, and an osazone C,H₁₁O₆(N, HC,H₃), m.p. 210°–212°, almost insoluble in water. By reduction with sodium-amalgam it yields α-glucoctitol C_sH₁₈O_s, which is casily soluble in water; it forms slender white needles, m.p. 141°. From a-glucoctose two glucononic acids may be prepared. Only one has been examined; this when reduced yields glucononose C, H18O, its phenylhydrazide $C_9H_{19}O_8N_2HC_6H_3$ is sparingly soluble in cold water and alcohol, m.p. 195° – 200° , its phenyl osazone $C_9H_{18}O_4(N_2HC_6H_3)_2$ is sparingly soluble in hot water and alcohol, m.p. 220°-223°. Unlike mannononose, glucononose does not ferment with yeast. By reduction glucononitol is obtained.

Mannoheptose C,H,4O, is obtained by the reduction of mannoheptonic acid. It crystallises from alcohol in fine needles, it has a sweet taste, m.p. 184°-135°. It is easily soluble in water, and does not ferment with yeast; its solution is dextrorotatory and exhibits bi-rotation, the constant value is [a]_D = +68°6°. It yields a difficulty soluble hydrazide C,H₁,O₂N₃H.C₆H₃,m.p. 197°-200°, and an osazone C,H₁₂O₃(N₂H.C₆H₃)₂, m.p. 200°. By reduction with sodium-amalgam it yields a heptahydric alcohol which is identical with the naturally produced body, perseit (Maquenne, A. Ch. [6] 19, 1; C. ½. 107, 583). It combines with hydrocyanic acid, and the compound decomposed by hydrochloric acid yields mannoctonic acid.

Mannoctose $C_8H_{18}O_8$ is obtained by the reduction of mannoctonic acid. It is easily soluble in water, has a sweet taste, and does not ferment with yeast. Its aqueous solutions are laworotatory, $(a|_{D} = -3.3^{\circ}$. It yields a hydrazone $C_8H_{10}O_1N_2H.O_2H_3$, difficultly soluble in water, mp. 212°; and an osazone $O_8H_{11}O_2(N_2H.O_2H)_2$, m.p. 228°. By reduction it yields the octohydric alcohol mannoctitol. It combines with hydrocyanic scid, and the compound decomposed by hydrochloric acid yields mannonononic acid.

Mannononose C, H₁, O, is obtained by the reduction of mannonononic acid. It is easily soluble in water and crystallises from alcohol, mp. about 180°, its solution is destrorotatory, [a] a

= +50° approx. It ferments readily and completely with yeast, and resembles dextrose in many ways. It yields a difficultly soluble hydrazide C_pH₁₀O₂.N₂H.O₂H₃, m.p. 223°, and an osazone, m.p. 217°.

Galactoheptose C,H,O, is obtained by the reduction of galacto-heptoic acid. Its hydrazide (m.p. 199°) is sparingly soluble; so is its osazone

(m.p. 220°).

Fructoheptose is obtained from lavulose by

the same set of reactions.

Rhamnohexose CH₂(CH.OH)₃COH is obtained by the reduction of rhamnohexolactone (Fischer a. Piloty, B. 23, 3102); it does not ferment with yeast, but exhibits all the characters of a sugar; the osazone is obtained in stellate groups of needles, m.p. 200°. On reduction the sugar yields rhamnohextol CH₂(CH.OH)₃CH₂OH; by the action of hydrocyanic acid on rhamnohexose, the lactone of rhamnoheptonic acid is obtained, which on reduction yields rhamnoheptose. The osazone forms yellow needles, m.p. 200°; by the action of hydrocyanic acid, rhamnocotonic acid is obtained. These compounds have the following optical activities:—

Rhamnose, $[a]_D = +8^\circ$. Rhamnohexose, $[a]_D = -61\cdot1^\circ$. Rhamnoheytose, $[a]_D = +8\cdot4^\circ$. Rhamnitol, $[a]_D = +10\cdot7^\circ$. Rhamnohexitol, $[a]_D = +11\cdot6^\circ$. Rhamnohexonolactone, $[a]_D = +83\cdot8^\circ$. Rhamnoheytolactone, $[a]_D = +55\cdot6^\circ$. Rhamnoctonolactone, $[a]_D = -51\cdot2^\circ$.

The reverse of the method of proceeding from one sugar to its next higher homologue—i.e. the production of a sugar containing one less carbon atom than the original one—has been effected by Wohl (B. 26, 730). When dextrose oxim (vide below) is treated with acetyl chloride it yields an acetyl compound from which hydrocyanic acid can be eliminated, and on hydrolysis of the resulting compound a pentose is obtained, which is d-arabinose; l-arabinose (ordinary arabinose) treated in the same way as dextrose yields a tetrose.

As is well known, mucic and saccharic acids are products of the oxidation of the sugars with nitric acid. The action of reducing agents on these bodies indicates their relationship to the sugars and helps to a clearer idea of the synthetical process.

Reduction of mucic acid. Sulphuric acid and zinc-dust reduce mucic acid to i-galactonic acid (Fischer a. Hertz, B. 25, 1247). The lactone crystallises in delicate prisms, m.p. 122–125°. It is optically inactive. By further reduction with sodium-amalgam i-galactose is obtained. This can be prepared as a crystalline mass, m.p. 140°–142°; it yields a hydrazide, m.p. 158°–160° and an osazone, m.p. 195°, which is identical with that obtained from the oxidation product of dulcitol (Fischer a. Tafel, B. 20, 3384).

i-Galactonic acid may be separated into the d- and l- acids by fractional crystallisation of the strychnine salts. The two acids yield respectively d- and l-galactose; d-galactose is identical with ordinary galactose. l-Galactose may also be obtained by the fermentation of i-galactose syrup. The sugar crystallises from alcohol, m.p. 162°-163°, its specific rotatory power is [a] = -78.6°, the phenyl-hydrazide

538

nielts at 158°-160° and the osasone at 192°-195°. From this, as well as from other matters connected with the synthetical portion of the work, it will be seen that d-, i-, and l- were intended to mean dextro-, inactive, and lawo-, as indicating the optical activity of the substances to which they are prefixed; but it is obvious the d-body is not always dextro-, nor the l- body lawo-. Hence the unsatisfactoriness already indicated.

Reduction of saccharic acid. Fischer (B. 23, 930; 24, 521) found that the lactone of saccharic acid was easily reduced by sodium-amalgam with formation of glycuronic acid. Thierfelder (H. 15, 71) has shown that this latter is further reduced to an acid $C_6H_{12}O_7$, which reaction Fischer has confirmed, and calls the acid gulonic acid and the corresponding sugar gulose. The relationship of these bodies to the others of the sugar group is shown here:

Dextrose . OH.CH₂(CH.OH), COH. Gluconic acid . OH.CH₂(CH.OH), COOH. Glycuronic acid . COOH.(CH.OH), COH. COOH.(CH.OH), CH.OH. COOH.(CH.OH), CH.OH. COOH.(CH.OH), CH.OH. COOH.(CH.OH), CH.OH. COOH.(CH.OH), CH.OH. COH.(CH.OH), COH.(CH.OH), CH.OH. CH.

Glycuronic acid obtained by the reduction of d-saccharic acid has $[a]_n = +19\cdot 1^n$, m.p. 175°–178°; d-gulonic acid obtained by the reduction of glycuronic acid yields a lactone, m.p. 180°–181°, $[a]_b = +55^\circ$; its phenyl-hydrazide is easily soluble in hot water and hot alcohol, m.p. 147°–149°; d-gulose obtained by the reduction of d-gulonic lactone is a colourless syrup, easily soluble in water and sparingly in absolute alcohol, it is oxidised by nitric acid to saccharic acid, it does not ferment with yeast.

Constitution. Dextrose and galactose are represented by the formula

CH,(OH).OH(OH).CH(OH).OH(OH).OH(OH).COH

and levulose by CH₁(OH).CH(OH).CH(OH).CO.CH₂OH and for the following reasons.

By oxidation dextrose and galactose yield acids containing the same number of carbon atoms as themselves, whilst levulose yields acids containing less carbon atoms than itself; dextrose and galactose yielding gluconic and galactonic acids CH₂(OH){CH(OH)}₂.COOH and by further oxidation saccharic and mucic acids COOH{CH(OH)}₄.COOH respectively; whilst levulose gives rise to trioxybutyric CH₂(OH){CH(OH)}₄.COOH, formic H.COOH, and glycollic CH,OH.COOH acids.

By reduction dextrose and galactose yield respectively mannitol and dulcitol; lævulose also yields mannitol. These yield hexacetyl derivatives, and are reduced by hydriodic acid to secondary hexyl iodide CH₂(CH₂),CHLCH₄ (Wanklyn a. Erlenmeyer, J. 1861. 731; 1862. 480); they are evidently hexahydric alcohols of normal hexane.

All three sugars combine with hydrocyanic acid to form nitriles which when boiled with hydrochloric acid yield different acids C,H₁₄O_s, which are reduced by hydriodic acid to heptoic acids; dextrose and galactose yielding normal heptoic acid CH₁(CH₂). COOH and lævulose yielding methyl-butyl-acetic acid CH₃ CH. COOH (Kiliani, B. 18, 3066; 19, 221, 767 a. 1128). Galactose, dextrose, and lævulose

form oxims or iso-nitroso-compounds by combination with hydroxylamine (Rischbieth, B. 20, 2673; Jacobi, B. 24, 696; Wohl, B. 24, 993). With phenyl-hydrazine, dextrose and galactose yield hydrazides

From the synthetic work above described, it is evident that the aldehyde formula belongs also to mannose, gulose, arabinose, xylose, and ribose, and also their synthetic homologues. Rhamnose, as is evident from its reactions, has also an aldehyde constitution; it appears to be methyl-arabinose.

Sorbose appears to be isomeric with lævulose. By oxidation it yields tri-oxyglutaric acid COOH.{CH(OH)},COOH and other acids, and by reduction it yields mannitol. It combines with hydrocyanic acid. By reduction with hydriodic acid and phosphorus it yields hexyl iodide (Kiliani a. Scheibler, B. 21, 3276).

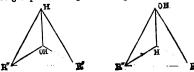

Little is known concerning the -on sugars. Maltose and lactose are probably anhydrides of equal molecules of dextrose and dextrose, and dextrose and galactose respectively; they yield acids (maltobionic and lactobionic) which on boiling with dilute mineral acids are decomposed into dextrose and gluconic acid and galactose and gluconic acid respectively. Both sugars thus appear to contain the dextrose-aldehyde group unaltered. Fischer (B. 21, 2633) has represented lactose as

CH₂(OH), {CH(OH)}, CH

Cane sugar appears to be differently constituted from either maltose or lactose.

It thus appears that the formula $CH_{+}(OH), \{CH(OH)\}, COH$ must be assigned to eight known sugars—i.e. d- and l- glucose; d- and l- gulose, d- and l- mannose, d- and l- galactose (the i- modifications being analogous to racemic acid, i.e. compounds of the d- and l-modifications).

Now, as this formula contains four asymmetric carbon atoms, according to Van't Hoff's theory there will be possible 2'=16 isomers, which in the case of the symmetrical derivatives, as the hexnhydric alcohols and dibasic acids, will be reduced to 10, of which ½2'=8 compounds are grouped in pairs (d- and l-) and ½2\frac{1}{2} = 2 inactive, amesotomic (Fischer, B. 24, 1836 a. 2683; Van't Hoff, La Chimie dans l'Espace and Dix Années dans l'Histoire d'une Théorie). Each of the groups R''——"HoH—"R' may be grouped in two positions represented thus

(the carbon atom being considered to be at the centre of the tetrahedron). For the sake of brevity these two groupings will be written $\begin{array}{ccc} H & OH \\ R'' & C & R' & and & R'' & C & R'. \end{array}$

The sixteen possible modifications of the glucose formula may then be expressed by the following symbols; in the case of the symmetrical derivatives (hexahydric alcohols and dibasic acids) Nos. 11-16 are identical with Nos. 5 to 10:-

Ħ Ħ ÓН Ĥ Since saccharic acid may be obtained either from glucose or its stereoisomeride gulose, then and L saccharic acids must be represented by formulæ corresponding to two of those numbered 5 to 10. Now, 7 and 8 may be eliminated, as they are optically inactive from internal compensation. Nos. 6 and 10 may be excluded for the following reasons: Glucose and mannose yield the same osazone, and consequently differ only in the arrangement of the groups round the asymmetric carbon atom next to the COH group. Other facts which confirm

COH

these formulæ are (1) 1-gluconic and 1-mannonis acids are both produced by the nitrile reaction from arabinose; (2) fructose reduced by sodiumamalgam yields mannitol and sorbitol; (3) man-nonic and gluconic acids can be converted, one into the other, by heating with quinoline; (4) all attempts to resolve gluconic and mannonic acids into two components have been unsuccessful.

If saccharic acid has the configuration 6 or 10, then manno-saccharic acid must have the configuration 7 or 8; but the latter are optically inactive, and therefore cannot be the configuration of manno-saccharic acid. Hence dand l-saccharic acid must have a configuration corresponding to 5 and 9; for convenience we may assign 5 to the d- and 9 to the l- bodies.

Now the two sugars corresponding to d-saccharic acid-i.e. d-glucose and d-gulose-must consequently have the configuration 5 and 11; but in order to determine which to assign to one and which to the other, we must consider xylose and arabinose.

Arabinose by the nitrile reaction yields l-glucose and xylose yields l-gulose; now since l-glucose and l-gulose are

then xylose and arabinose must

According to theory, there will be 23 = 8 isomeric pentoses, but when the formula becomes symmetrical, the asymmetry of the centre carbon is destroyed, and there will be only three isomeric pentahydric alcohols and three isomeric trioxy-glutaric acids, of which two are optically active, i.e.:

The same applies to the pentahydric alcohols. As arabitol and the tri-oxy-glutaric acid from arabinose are both lævorotatory, whilst the forresponding compounds from xylose are optically inactive, the formula marked (a) is the formula for xylose, and (b) is the formula for arabinose, (9) and (15) being the formulæ for l-gulose and l-glucose respectively.

& glucose

The other di-basic acids known are mucic acid, which is optically inactive; allomucic acid, formed by the action of pyridine on mucic acid, which is also optically inactive; another isomeride of mucic acid, which is optically active, obtained by treating galactonic acid with quincline and oxidising the product; and iso-saccharic acid. We have as yet not sufficient data to write the constitution of these with certainty.

So far we have considered the sugars in general; we must now turn to a description of the individual members of the group.

Class I. Ose sugars. Arabinese $C_{\nu}H_{10}O_{\nu}$. It does not occur in sature.

Formation.—By the action of dilute acids on metapectic acid, a constituent of bestroot, gum arabic, cherry-tree gum, gedda gum, gum tragacanth, and many other gums (Scheibler, B. 1, 58, 108; 6, 612; Claësson, B. 14, 1271; Martin, Sachsse's Phytochem. Unter. p. 69; Bauer, J. pr. [2] 84, 47; Kiliani, B. 19, 3030; v. Sandersleben, Sachsse, l.c., p. 90; O'Sullivan, C. J. 1884. 41, 1891, 1029; Stone a. Tollens, A. 249, 257; Stone, Am. 12, 435; wheat and rye bran (B. 23, 3110). Owing to the fact that most of the above gums yield galactose besides arabinose, the two were for some time confused (H. Kiliani, B. 13, 2304; 15, 34; Claësson, B. 14, 1270; B. C. 205; Scheibler, B. 17, 1729; E. O. v. Lippmann, B. 17, 2238). Arabinon yields on hydrolysis arabinose alone (O'Sullivan, C. J. 1890. 59).

Preparation.—A dextrorotatory gum, or one yielding little mucic acid when exidised by nitric acid, is selected. A solution containing 30-40 g. per 100 c.c. is heated to 100° in a water bath and digested at that temperature with 2 p.c. sulphuric acid for 10-15 minutes. The solution is then cooled, neutralised with milk of lime, baryta water, or calcium or barium carbonate, and hot alcohol, S.G. 0-83, added as long as a precipitate is formed. The clear abcoholic solution is poured off the pp. which in a short time collects at the bottom, and evaporated in a vacuum to a syrup. After standing a few hours arabinose crystallises out in well-formed rhombic prisms with monoclinic terminations, and is purified by recrystallisation from water.

Formula and synthesis. See general part. Properties.—Arabinose crystallises in fine rhombic prisms out of aqueous solution. The termination and habitat of the crystals vary with the source. From alcoholic solutions it separates in sphenoids. The crystals melt at 160°. Its specific rotatory power is [a]_p = +104.5° for 10 p.c. solution at 20°C.; in more concentrated solutions it is higher, [a]p = + 110° being observed for nearly saturated solutions. Freshly-prepared solutions possess bi-rotation, an angle of [a]_D = 156.7° having been observed Scheibler, Lc.; O'Sullivan, Lc.; E. O. v. Lipp-mann, Lc.; Bauer, L. V. 36, 304; Tollens, A. 257, 160; Groth, B. 6, 615; Griess a. Harrow, B. 20, 3111). The specific gravity of aqueous solutions does not increase regularly with the strength, being less in proportion for high concentrations than for low ones. The S.G. of a solution confaining 10 g. in 100 c.c. at 15.5° is 1.0385-1.0384.

Action of acids. The action of boiling dilute mineral acids destroys much of the opticity and K. of arabinose in a short time (O'Sullivan, 1884, 55). The first products of the change have not been studied. When, however, the action is continued for a considerable time, no lavulinic acid is produced, but furfural is present in large quantities (Ganz, Stone, a. Tollens, B. 21, 2148; 23, 3791). Chalmont a. Tollens (B. 24, 694) obtained 52·7 p.c. furfural by precipitating the distillate from the products of action of acids with phenylhydrazine acetate. Formic and aceto-propionic acids and humus substances are also present (Conrad a. Guthzeit, B. 18, 2905).

Reduction.—Treated with sodium-amalgam in acid solutions, arabinose yields arabitol, a body resembling sorbitol, m.p. 102°. This body

does not reduce Fehling's solution, and is optipally inactive (Kiliani, B. 20, 1233)

Oxidation .- By oxidation with nitric acid arabinose yields arabonic acid (lævorotatory trioxyglutaric acid), and by violent oxidation at an elevated temperature oxalic acid (Kiliani, B. 21, 8006). Bromine also oxidises it to arabonic acid C.H., O., m.p. 89° (Bauer, J. pr. [2] 34, 47; C. C. 1877, 732; Kiliani, B. 19, 3031; 20, 345). It is oxidised by alkaline solutions of metallic oxides, 100 c.c. of Fehling's solution being reduced by 0.4303 g. arabinose, and 100 c.c. of Sachsse's solution being reduced by 0.4375 g. arabinose (Bauer, L. V. 36, 304). Its K = 108 110 (O'S., .c.), i.e. 100 pts. of it reduce as much CuO as 108-110 pts. dextrose.

Fermentation.—Arabinose does not seem to be capable of fermentation with yeast (Stone a. Tollens, l.c.; Scheibler, l.c.; v. Lippmann, B. 17, 2238); with Bacillus ethaceticus it ferments with the production of ethyl alcohol, acetic, formic, and carbonic acids, and hydrogen (Frankland a. MacGregor, C. J. 1892. 737).

Compounds with cyanogen. By the nitrile reaction arabinose yields a mixture of l-gluconic and 1-mannonic acids (Kiliani, B. 19, 3029; 20, 282, 339, 2710; Fischer, B. 23, 2611; 24, 539). The first product of the action of HCy on arabinose seems to be a compound of both bodies. HCl converts this into a crystal-line amide C_cH₁₈NO_s, which on treatment with baryta yields the acids just mentioned.

Hydrazine compounds. Arabinose yields with phenylhydrazine, just as dextrose (q.v.) does, an osazone, m.p. 157°-158° (Scheibler, B.

17, 1729; Kiliani, B. 20, 345).

Compounds with diamines. With o-diamidobenzene, arabinose yields arabinose-o-diamidobenzene C.H. (NH), C.H.O. It is a neutral body, not reducing Fehling's solution, and is dextrorotatory, m.p. 235° with decomposition; it withstands boiling with dilute hydrochloric acid or potash, and yields a hydrochloride and hydrobromide. Arabinose-m-p-diamido toluene C₆H₃(CH₃)(NH)₂:C₅H₈O₄, m.p. 238°, and arabino γ diamido benzoio acid COOH.C₆N₂:(NH)₂:C₅H₈O₄ + 2H₂O, m.p. 235°, have also been obtained (Griess a. Harrow, B. 20, 3111). Arabinose gives colour reactions with orcinol and phloroglucinol (Wheeler a. Tollens, A. 254, 314; 260, 304).

Ribose. Fischer a. Piloty, B. 24, 4214.

When certain carboxylic acids of the sugar group are heated with quinoline or pyridine, they are converted with stereo-isomeric acids.

When arabonic acid OH.CH₂(CH.OH)₃.COOH is treated in this manner it yields a new acid COOH.(CH.OH), CH,OH, which the authors name ribonic acid; ribonic lactone crystallises from solution in ethyl acetate in long prisms, m.p. 72°-76°, does not reduce Fehling's solution, and is easily soluble in water, alcohol, and acetone. Its specific rotatory power is $[\alpha]_{D20^0} = -18$. Its phenylhydrazide forms colourless needles, m.p. 162°-164°. Ribonic acid may be converted into arabonic acid by heating with quinoline.

By reducing ribonic lactone with sodiumamalgam, it yields the new sugar ribose, which forms a phenylhydrazide crystallising from alcohol in colourless crystals, m.p. 154°-155°; ribose-osazone is identical with arabinose-

osazone. By oxidation ribonic acid yields trioxy-glutaric acid, which differs from the tri-oxyglutaric acid obtained by the oxidation of xylose, but which is also optically inactive. By the further reduction of ribonic lactone, a pentahydric alcohol was obtained which has been found to be identical with the naturally occurring adonitol, obtained from Adonis vernalis (Fischer, B. 26, 636).

Xylose. C₅H₁₆O₅. It does not occur free in

Formation.—It is obtained by the action of dilute boiling acids on xylan or wood gum (Koch, B. 20, ref. 145; Wheeler a. Tollens, B. 22, 1046; A. 260, 289; Winterstein, H. 17, 381; Stone a. Test, Am. 15, 195), on the carbohydrate from the epidermis of Psyllium gallicum (Bauer, A. 248, 140), on vegetable amyloid (Winterstein, Z. P. C. 17, 353), on brewer's grain (Stone a. Tollens, A. 249, 227; 271, 55), on jute (Wheeler a. Tollens, l.c.), and other vegetable bodies (Voswinkel, C. C. 1891, 2, 655; Hebert, Ann. Ag. 16, 358; 18, 261; Stone a. Lotz, B. 24, 1657; Allen a. Tollens, B. 23, 137; Bertrand, Bl. [3] 5,

Preparation.—Xylose may be prepared by extracting straw or any other of the above-mentioned materials by 5 p.c. soda, precipitating the wood gum from the solution by alcohol, and hydrolysing this by boiling with dilute sulphuric acid. The digested solution is treated in the same way as described in the case of arabinose, and the xylose may be easily purified by crystallisation from water.

The formula and synthesis have already been

discussed in the general part.

Properties. - Xylose is easily soluble in water; 100 pts. of water at 20.3° dissolve 117 pts. of xylose; it is insoluble in absolute alcohol, 90 p.c. alcohol will dissolve in 10 c.c. 0.4 g. sugar at 19° (Bertrand, Bl. [3] 7, 499). Its solutions are optically active, freshly-prepared solutions having about four times the constant eptical activity (Parcus a. Tollens, A. 207, 160). For a 10 p.c. solution at 20° $[a]_D = +19.3^\circ$ (Parcus a. Tollens, l.c.; Bertrand, l.c.). Schulze a. Tollens (A. 271, 40) give the formula $[a]_D = +18.095 + 0.06986p$ at $15^\circ - 20^\circ$, where p = percentage of xylose in solution. Xylose frequently crystallises in prisms belonging to the ortho-rhombic system. Its solutions are not fermentable by yeast. It reduces Fehling's solution, K = 109.6, agreeing in this respect very closely with arabinose (Bertrand, l.c.). Boiled with acids it yields about 50 p.c. furfural (Günther a. Tollens, B. 23, 1751; Chalmont a. Tollens, B. 24, 694; Bertrand, l.c.).

It is reduced by sodium-amalgam to a pentahydric alcohol xylitol (Bertrand, Bl. [3] 5, 554; Fischer a. Stahel, B. 24, 528). It is oxidised by bromine to xylonic acid (Bertrand, l.c.; Allen a. Tollens, A. 260, 306); it is oxidised by nitric acid to inactive tri-oxy-glutaric acid C, H,O, (Fischer, B. 24, 1836). By the nitrile reaction xylose yields l-gulonic acid, the stereo-isomeride of l-gluconic acid (Fischer a. Stahel, B. 24, 528; Fischer, B. 23, 2625; Fischer a. Curtis, B. 25, 1025).

With phenyl hydrazine it yields an osazone m.p. 160°. Warmed with phloroglucinol and hydrochloric acid, it gives a cherry-red coleura-

tion, just as arabinose does under the same conditions (Tollens a. Mayer, B. 21, 3508; Wheeler a. Tollens, B. 22, 1046).

Isodulcite. *hamnodulcite Rhamnose.

 $C_6H_{12}O_5.H_2O.$ Preparation.—Rhamnose is obtained, together with other bodies, by the action of hot dilute acids on quercitrin, hesperidin, xanthorhamnin, naringin, and frangulin (Rayman a. Kruis, Bl. [2] 48, 632; C. C. 1888, 6; Hlasiwetz a. Pfaundler, A. 127, 362; Liebermann a. Hörmann, A. 196, 323; Kruis, A. 196, 333; Berend, A. 196, 328; Rigaund, A. 90, 292; Will, B. 18, 1316; 20, 297 and 1186; Dehn, Zeit. d. Ver. 15, 562; Rayman, Bl. [2] 47, 668; Tanret, Bl. 49, 20; Thorpe a. Miller, C. J. 1892. 8).

Properties .- Rhamnose forms fine crystals, which have a sweet taste, and a composition corresponding to the formula CoH12O3.H2O; by careful drying it loses water and then melts at 90°-110° (Websky, B. 18, 1318; Hirschwald, A. 196, 330). It is easily soluble water, and its solutions are dextrorotatory, $[a]_D = +9^{\circ}$. Freshlyprepared solutions show bi-rotation (Schnelle a. Tollens, A. 271, 61). In alcoholic solutions the optical activity decreases as the proportion of alcohol to water increases, until the solution becomes lævorotatory (Rayman a. Kruis, C. C. 1888. 6). It reduces Fehling's solution, 1 c.c. being reduced by 0.0052-0.0055 g. rhamnose (K = 91-96) (Rayman a. Kruis, l.c.). Its solution does not ferment with yeast.

Action of acids. Boiled with moderately strong acids furfural is evolved (Maquenne, C. R. 109, 603). Concentrated nitric acid converts it

into a nitrate.

Oxidation .- Nitric acid oxidises rhamnose to tri-oxy-glutaric acid (Will a. Peters, B. 22, 1697). Malin (A. 145, 197) obtained an acid CoH10Oo. Bromine water oxidises it to rhamnonic acid CaH12Oa, which is obtained in the form of the lactone $C_0H_{10}O_3$, m.p. 148° (Will a. Peters, B. 21, 1813; Rayman, B. 21, 2046). With bromine and silver oxide it is oxidised to acetaldehyde and acetic acid (Herrig, Chem. Zeit. 1887, Rep. 145; M. 8, 227).

Reduction .- Sodium-amalgam reduces rhamnose to rhamnitol CH3(CH.OH)1.CH2OH, which crystallises from alcohol or acetone in triclinic prisms, m.p. 121°, and has a sweet taste (Fischer

a. Piloty, B. 23, 3102).

Compounds .- With phenylhydrazine rhamnose yields a hydrazide $C_sH_{12}O_s:N_sHC_sH_s$, m.p. 159°, and an osazone $C_1H_{12}N_sO_s$, m.p. 180° (Will, B. 20, 1186; Fischer a. Tafel, B. 20, 1089, 1091 a. 2566). With aniline it forms a compound C.H. O.NC.H., m.p. 118° (Rayman a. Kruis, l.c.). With ammonia and ethylaceto-acetate it forms rhamnodiasine $C_{18}H_{32}O_8N_2$, m.p. 186° (Rayman a. Chodounsky, B. 22, 304 and 3247).

Rhamnose combines with hydrocyanic acid to produce rhamnonamide. The lactone C,H12O6 crystallises in needles, melting-point 168°; this is reduced by hydriodic acid and phosphorus to normal heptoic acid (Fischer a. Tafel, B. 21, 1657 a. 2178). Rhamnose hexoic acid lactone is reduced by sodium-amalgam to a sugar (Fischer, B. 22, 2204; Fischer a. Tafel, B. 23, 8102). Sodium rhamnose C₂H₁₂O₂Na, is precipitated by adding sodium ethylate to an alcoholic solution of rhamnose (Liebermann a.

Hamburger, B. 12, 1186). With benzoyl chloride tri- and tetra- rhamno-benzoates are formed: with acetic anhydride rhamno-tetracetate (Rayman, B. [2] 47, 668). From thermo-chemical considerations rhamnose appears to be methylxylose (Stohmann a. Langbein, J. pr. [2] 45, 805). Fucose C.H,2O, is obtained by the hydrolysis

of fucus. The sugar forms microscopic needles. Its solution has a sweet taste and is levorotatory, $[\alpha]_{p} = -77^{\circ}$. With phenyl-hydrazine it forms a hydrazide, melting-point 170°, and an osazone, melting-point 159° (Bieler a. Tollens, A. 258, 110; Günther a. Tollens, B. 23, 2585). Fucose appears to be methyl-arabinose (Stohmann a. Langbein, l.c.).

Dextrose. d-glucose, glucose, starch-, corn-, grape-, honey-, diabetic-sugar. (Ger. Krümmelzucker, Traubenzucker; Fr. Sucre de raisin.)

C. H12O. and C. H12O. + H2O.

Occurrence.-Dextrose is widely distributed throughout the vegetable kingdom, being usually accompanied by lavulose and cane sugar. The most important sources are honey, most fruits, the sap of plants, seeds. It occurs in the animal kingdom in the liver, blood, and other parts of the body, and in diabetic urine (S. Sachsse, Die Ch. und Phys. der Farbst. Kohlenhydrate u. Protein subst., Leipzig, 1877; F. Mack, J. 1869, 892; Girard, B. 17, 17c; Neubauer, Fr. 12, 39; Gorup-Besancz, B. 4, 906; Petit. B. 6, 1313; v. Schneider, A. 162, 235; Report on Sorghum and Cornstalles, Dep. of Agr., Report No. 35, Washington, 1881; Hermann a. Tollens, A. •230, 50; Vogel, B. 15, 2271; Fischer a. Bödecke, A. 117, 111; De Bary, Hoppe-Seyler's Medic. Ch. Unt. p. 72; Hoppe-Seyler, Handb. d. phys. Ch. Ana., 1883, 301; Klason, B. 19, 2541; Welmer, Inaug. Diss., Göttingen, 1886, 40; O'Sullivan, C. J. 1886, 58; Welmer a. Tollens, B. 19, 707; Seegen a. Kratzschmer, Pf. 22, 206; Kütz, Pf. 24, 52; Boussingault, C. R. 91, 639; J. Sieben, B. C. 1885, 134; Hermann a. Tollens, A. 230, 50; Müller, Ann. Agronom. 13, 88; Seegen, Pf. 37, 348; 39, 121; 40, 48; Cuisinier, C. C. 1886, 614; H. Thoms, B. 21, 1916a; Reali, G. 17, 325; Maquenne, A. Ch. [6] 17, 495).

Formation .- By the action of acids and ferments on the following glucosides: amygdalin (Schmidt, A. 119, 92; Hesse, l.c., 176, 112); populin (v. Lippmann, B. 12, 1648b); ruberythria acid (Liebermann a. Bergami, B. 20, 2247); salicin (Schmidt, A. 119, 97; Hesse, l.c., 176, 112); lupinin (B. 11, 2200b); hesperidin (Tanret, Bl. 49, 20); phlorizin (Rennie, C. J. 1887, 636). Other glucosides yield dextrorotatory, reducing, fermentable, and crystallisable sugars, but there is not sufficient evidence to prove with certainty that they are dextrose. These are: esculin (Rochleder a. Schwarz, A. 87, 186; Zwenger, i.c., 90, 76); arbutin (Hlasiwetz a. Grabowski, Ar. Ph. 141, 329); coniferin (Tiemann a. Har-

mann, B. 7, 608).

By the action of dilute acids the following carbohydrates yield dextrose, alone or with other glucoses. Some of them are also hydrolysed to dextrose by ferments:

a- and B- amylan yield dextrose.

Cellulose yields dextrose (Flechsig, H. 7, 523; Lindsay a. Tollens, A. 267, 370).

Glycogen yields dextrose.

Lichenin vields dextrose.

Tunicin Starch Dextrin Maltose

Lactose vields dextrose and galactose. Cane sugar yields dextrose and lævulose. Raffinose yields dextrose, levulose, and

galactose.

Preparation .- Dextrose can be prepared from any of the substances above mentioned, but it is in many cases difficult to obtain it in any quantity in the pure state. Starch and sucrose are the bodies usually employed, and we find that lactose can also be used with advantage.

(a) A white saccharum (the commercial glucose obtained by the action of acids on starch) with an optical activity approaching that of dextrose is selected. This is scraped as fine as possible, and treated with boiling ethyl alcohol 8.G. 820. On cooling, the clear saturated solution is separated from the undissolved syrup and a little previously prepared dextrose added to it. Crystallisation soon begins and continues for some time pa crop of fairly pure dextrose is thus obtained. Further purification can be effected by melting the crystals in 8-10 p.c. boiling water and adding dry boiling methyl alcohol until a slight cloud is produced. Anhydrous dextrose in a state of great purity separates abundantly from this solution. Or the saccharum is melted in 5 or 6 p.c. water, allowed to crystallise, the crystals pressed and further purified by treatment with methyl alcohol as described.

(b) A 25 p.c. aqueous solution of crystallised sucrose is taken and heated to 50°-55° and 2-3 p.c. pressed brewers' yeast stirred in (Tompson, E. P. 8686, 1884), the temperature is maintained for 2-3 hours, when the sucrose is completely inverted—that is, converted into dextrose and lævulose. The solution is then evaporated in a vacuum to a syrup, S.G. 1.5 or thereabouts. On standing for a short time this solidifies to a crystalline mass; it is washed with cold alcohol. S.G. 830, and the residue dissolved to saturation in alcohol of the same strength. Dextrose soon begins to crystallise out; the crystals can be further purified by dissolving in

methyl alcohol and recrystallisation.

Sucrose may also be inverted by digestion with sulphuric acid, the acid separated by baryta water, and the filtrate from the barium sulphate evaporated to a syrup and treated in the way mentioned. Inversion by yeast yields the best result. Soxhlet (J. pr. [2] 21, 242) recommends that inversion be effected by alcoholic hydrochloric acid. 480 c.c. of strong hydrochloric acid are mixed with 12 litres of alcohol, S.G. 810, in a glass vessel, the mixture heated 45°-50°, 4 kilos. powdered sucrose stirred in, and the whole maintained at that temperature for two hours. When cool a little previously prepared anhydrous dextrose is added, and in a few days there is an abundant crystallisation of dextrose. This can be purified by crystallisation from methyl alcohol. Should any colour be developed, the aqueous solution is treated with animal charcoal and again concentrated in a vacuum. Under such sircumstances it is better to begin again, for if proper care be taken no colour need be produced.

An aqueous solution containing 25 p.c.

lactose and 3 p.c. sulphuric soid is digested in a water-bath for three hours, care being taken by continued agitation that no colour is developed, the sulphuric acid is separated by baryta water, and the filtrate concentrated to a syrup containing 76-80 p.c. solid matter. On standing this solidifies, and after a few days is treated with boiling methyl alcohol; this dissolves out the dextrose, leaving the galactose undissolved; the former soon crystallises from the saturated methyl alcohol. A recrystallisation yields the pure body in moderately large, well-defined crystals.

Hydrous dextrose CaH12Oa.H2O can be obtained from any of the above preparations by dissolving in 12 to 20 p.c. water, and allowing to crystallise. If honey is used as a source of dextrose, any sucrose it may contain should be inverted by yeast or acids, and the residue obtained by evaporation crystallised from methyl alcohol as in the case of inverted sucrose. pure product may be obtained in a few crystallisations.

Formula and synthesis. See first part on the sugars generally.

Properties .- Dextrose crystallises out of 93-95 p.c. ethyl or methyl alcohol in the anhydrous state. Anhydrous crystals may also be obtained by special treatment from concentrated aqueous solutions at 30°-35°. As a rule aqueous solutions deposit crystals containing one molecule of water of crystallisation. Anhydrous dextrose crystallises in rhombic, hemibedric forms; the axial relationship is a:b:c=0.704:1:335. Hydrated dextrose forms hemimorphous crystals; the elements are a:b:c = 1.7350:1:1.9080, $\beta = 97^{\circ} 59'$ (F. Becke, M. 10, 231). Well-defined crystals of both varieties are difficult to obtain; usually the first separates as a powder and the second in cauliflower-like masses; both dissolve easily in water, the first with evolution of heat. Hydrated dextrose dissolves easily in strong ethyl and methyl alcohol, but the anhydrous sugar is almost insoluble in them. It is insoluble in ether and hydrocarbons, slightly soluble in aniline, acetic acid, and acetic ether. Hydrated dextrose easily loses its molecule of water of crystallisation when exposed in a vacuum over sulphuric acid, or when heated gently. The anhydrous sugar melts at 1440-146° (Hesse, A. Ch. 176, 106); its specific gravity is, according to Guerin-Varry a. Heintz, 1.386; according to Bödecker, 1.5384 (v. Lippmann, Zuckerarten, p. 12). Dextrose is not so sweet as cane sugar. Behr (B. 15, 1106) finds it } as sweet, and T. Schmidt (B. C. 1887, 405) that 1.53 pts. of dextrose are as sweet as 1 part of cane sugar. An aqueous solution of 10 g. dry dextrose in 100 c.c. of solution at 17.5° has a specific gravity of 1-0381 (water at $17\cdot5-1$) (Salomon, B. 14, 2710). This is fairly accurate, K=100. Its solutions rotate the plane of polarisation of a ray of polarised light to the right. According to Hesse a. Tollens (B. 17, 2284), the amount of rotation for the D line is expressed by the formula $[\alpha]_D = 52.5 + .018796P + .00051688P^*$ for anhydrous dextrose, and

[s]_D = 47·73 + 015584P + 0003888P? for hydrated dextrose, in which P is the percentage of the two varieties respectively in solution. In solutions containing 10 p.c. dry sugar and theresbouts, the

SUGAR. 541:

factors $[a]_p = 52.7$ and $[a]_1 = 58.8$ are sufficiently accurate, but probably a shade too low. These values are not materially affected by the temperature. The presence of some inactive bodies in the solution appears to have some effect (Pribram, M. 9, 395); bodies such as potash, soda, lime, &c., which act on dextrose reduce its optical activity; other bodies, such as urea, do not alter it (N. Wender, B. 24, 2200). Freshlyprepared solutions have a greater optical activity than those which have stood a few hours. F. Urech (B. 17, 1547) has observed a rotation 2.19 times greater than the constant value. Parcus a. Tollens (A. 257, 160) observed an angle of $[a]_D = 105 \cdot 16$ in a 10 p.c. solution $5\frac{1}{9}$ min. after commencing solution. This phenomenon is called bi-rotation; the optical activity quickly falls, and the constant value is reached in about six hours in the cold and immediately on boiling. bi-rotation is also immediately destroyed by potash (O'Sullivan a. Tompson, C. J. 1890, 920), or ammonia (Schulze a. Tollens, A. 271, 49). Dextrose when produced by the inversion of cane sugar at a low temperature is set free in the birotatory state (O'Sullivan a. Tompson, l.c.). Only crystallised dextrose exhibits this phenomenon; fused dextrose does not show it (Hesse, A. 176, 113). A solution of dextrose in strong alcohol retains its bi-rotation (?) The dispersive power of dextrose solution is practically the same as that of quartz (Hoppe-Seyler, Fr. 3, 1866, 412). The ratio between the specific rotatory power for the C and D lines respectively is 1:1.258 (Grimbert, J. Ph. [5] 16, 295 and 345). The heat of combustion of dextrose is +677.2 cal., and the heat of formation +300.8 cal. (Berthelot a. Recoura, C. R. 104, 1571).

Action of heat. When the dry sugar is heated to 170°, a molecule of water is eliminated and dextrosan C.H.O. is produced, which may be reconverted into dextrose by the action of water and dilute acids. If the temperature is raised to 200°, gas, water, and volatile acids are given off, and if the heating be continued without raising the temperature, a brownish black mass is finally left. This substance is soluble in water and constitutes the colouring matter (caramel) sused in beer, wine, cooking, &c. Should the temperature be raised, carbon monoxide, dioxide, and methane are evolved, and aldehyde, furfural, acetone, metacetone, propionic, acetic, and formic acids distil over, and a black carbonaceous mass is left. If the hydrate be heated for a considerable time in a closed tube a fluid is obtained which absorbs oxygen and nitrogen (?) from the air (Thénard, C. R. 52, 795).

Action of acids. Dextrose is dissolved by strong sulphuric acid without blackening, dextrose-sulphuric acid being formed (Péligot, A. Ch. [2] 67, 170); from this solution alcohol precipitates a compound of diglucose with alcohol (Musculus a. Meyer, B. 14, 850). Similar compounds are produced by the action of chlorosulphotic acid (Claësson, J. pr. [2] 20, 1). A mixture of sulphuric and nitric acids converts dextrose into a nitro-compound (Carey Lea, Bl. [2] 10, 415). Dextrose phosphoric acid is said to exist (Amato, B. 4, 418). Several acetyl derivatives have been described. Dextrose discotate Callago (Callago), and dextrose triacetate

C_cH_sO_s(C_cH_sO_s)_s are amorphous, soluble in water, alcohol and ether (Schützenberger a. Naudin, Bl. [2] 12, 107, 204; Liebermann a. Hörmann, B. 11, 1619; Herzfeld, B. 13, 265). Dextrose pentacetate C_cH_sO(C_sH_sO_s)_s is prepared by the action of acetic anhydride and zinc chloride on dextrose, m.p. 111-112 (Erwig a. Koenigs, B. 22, 1464, 2207). Didextrose octoacetate C₁₂H₁₄O₂(C₂H₂O₂), is prepared by the action of acetic anhydride and sodium acetate on dextrose, m.p. 134 (Herzfeld a. Erwig a. Koenigs, l.c.). Dextrose-monochlorhydrintetracetate is formed by the action of acetyl chloride on dextrose (Culley, C. R. 70, 401). Tri-, tetra-, and penta-benzyl (C₆H₁(C₇H₅O)₅O₆) dextroses are obtained by the action of benzoic chloride and potash on dextrose (Skraup, M. 10, 389; Kueny, H. 14, 330; Panormoff, J. R. 23, 375). Compounds of dextrose with other organic acids have been prepared (Berthelot, A. Ch. [3] 54, 74; Gm.-K. 7, 764; v. Lippmann, Zuckerarten, p. 40; Baumann, B. 19, 3218; Colley, C. R. 76, 436). If dextrose is boiled with dilute sulphuric acid the specific gravity of the solution gradually increases for some time, apparently from the fixation of the elements of water. On continued boiling the solutions become coloured, brown humus substances, acetopropionic and formic acids, are produced (Malaguti, A. Ch. [2] 59, 407; Tollens a. Grote, A. 175, 181; 206, 207; Wohl, B. 23, 2084). Dilute hydrochloric acid produces similar results, but more rapidly. Gummy bodies are also produced (Grimaux a. Lefèvre, C. R. 103, 146). See also Conrad a. Guthzeit (B. 18, 439; 19, 2569) and Wehmer a. Tollens (B. 19, 707).

Action of alkalis. Alkalis give a brownish colour with dextrose solution, quickly on heating, slower in the cold, with production of acetal, acetone, and lactic, acetic, and formic acids. Other bodies of unknown composition are also formed, such as glucinic, saccharumic and japonic acids. When potash is used oxygen is absorbed. With calcium hydroxide, saccharin or calcium saccharinate is also produced; this is not one of the products of the action of potash (Emmerling a. Loge, B. 14, 1005; 16, 838; Henry, B. 14, 2272; Breuer a. Zincke, B. 13, 638; Rochleder a. Kawalier, J. pr. 94, 403; Hoppe-Seyler, B. 4, 346; Kiliani, B. 15, 700; Nencki a. Sieber, J. pr. [2] 24, 498; Péligot, A. Ch. 30, 75; Mulder, A. Ch. 36, 260; Reichardt, Z. 1870. 401; v. Lippmann, Zuckerarten, p. 22; Péligot, B. 13, 196; Scheibler, B. 13, 212; Kiliani, B. 15, 701; Cuisinier, v. Lippmann, Zuckerarten, p. 25; Scheibler, B. 16, 2434). Thénard (C. R. 52, 444) obtained bitter bodies containing 10-19 p.c. nitrogen, by acting on dextrose with ammonia; they absorb oxygen from the air, and resemble certain nitrogenous humic acids. Tanret (Bl. [2] 44, 102) obtained two volatile bases: a-glucosine C.H.N. b.p. 136° and \$-glucosine C,H10O2 b.p. 160°, by heating dextrose with strong ammonia. Heated with aniline, dextrose anilide is produced (Schiff, A. 140, 123; Sorokin, B. 19, 298).

Reduction.—Nascent hydrogen reduces dextrose in alkaline solutions to mannitol, but not in neutral or acid solutions (Linnemann, A. 128, 186; Dewar, Z. 1870. 418; Bouchardat, Bl. [2] 16, 38; Krusemann, B. 9, 1466). Under the most

favourable conditions the yield does not exceed 10 p.o. If the reduction be carried on at a high temperature other fatty alcohols are formed. Meunier (C. R. 111, 49) obtained sorbitol by reducing dextrose with sodium-amalgam.

Oxidation .- Gluconic acid C.H.,O, is produced by oxidising dextrose with mercuric oxide (Heffter, B. 22, 1049; Herzfeld, A. 245, 27) or with chlorine or bromine and subsequent treatment with silver oxide (Hlasiwetz a. Habermann, A. 155, 122; 156, 253; Kiliani, A. 205, 182; Kiliani a. Kleeman, B. 17, 1298; Herzfeld, A. 220, 335, 358), or by the action of Bacterium aceti (Brown, C. J. 1886. 179; Boutroux, C. R. 1880. 236). Oxygen has no action on dextrose in neutral or acid solutions, but it is absorbed by alkaline solutions. Ozone oxidises dextrose to saccharic and formic acids (Renard. A. C. 5, 17, 289). Platinum black acts similarly (Loew, B. 23, 865). Nitric acid oxidises dextrose to saccharic acid C_sH₁₀O_s, and finally to oxalic, formic, and carbonic acids (Liebig, A. 113, 1; Heintz, P. 51, 183; Hornemann, J. pr. 89, 304; Kiliani, A. 205, 172; Guérin-Varry, A. 8, 31; Sohst a. Tollens, Z. 11, 99). Iodine when acting on alkaline solutions of dextrose yields a little iodoform (Lieben, A. Suppl. 7, 228; Hermann a. Tollens, B. 18, 1335; Millon, C. R. 21, 828). Alkaline solutions of many metallic oxides oxidise dextrose, in some cases being reduced to the metal, in others to lower oxides. Potassium ferrocyanide, potassium permanganate, indigo, picrio acid, litmus, &c., oxidise dextrose also. The chief products are formic, oxalic, glycollic, and carbonic acids. Some of these reactions are employed for the quantitative estimation of dextrose (Tollens, B. 16, 921; Herzfeld, Zeitschr. d. Ver. d. Rüben-zucker-Ind. 37, 337; Habermann a. Hönig, B. 15, 2624; Worm-Müller a. Hagen, Pf. 22, 325; B. 13, 2096 a. 2442; Herzfeld a. Bruhns, Zeitschr. d. Ver. d. Rübenzucker-Ind. 36, 110; Reichardt, A. 127, 297; Felsko, A. 149, 856; Beyer, A. 131, 353; Claus, A. 147, 115; Smolka, B. 20, 167; M. 8, 1).

Fermentation.—Under the influence of

Fermentation.—Under the influence of various species of saccharomyces and other organisms, dextrose ferments, yielding alcohol and carbon dioxide as the chief products, glycerol, succinic acid, and small quantities of other bodies are formed at the same time. Bacteria decompose dextrose in other ways, one yielding chiefly lactic acid, another butyric, another cel-

lulose, &c. (v. FERMENTATION).

Compounds with acids (v. Action of acids). Compounds with bases. Potassium and sodium dextrose $C_bH_{11}KO_a$ and $C_bH_{11}NaO_a$ are prepared by adding potassium or sodium ethylate to a solution of dextrose in strong alcohol. A white, bulky precipitate is obtained, which is very hygroscopic, and decomposed by water (Hönig a. Rosenfeld, B. 10, 871; Franchimont. B. 10, 994). The compounds with the alkaline earths are differently constituted, being apparently a combination of the sugar and base. They are formed by mixing alcoholic solutions of the base and sugar, or by precipitating their mixed aqueous solutions with alcohol. Lime forms C₄H₁₂O₆,CaO.H₂O, C₆H₁₂O₆,CaO, 2C,H,O,BCaO.H,O, 2C.H.2O.3CaO.2H.O. 4CaH12Oa.8CaO, and similar compounds are

formed with baryta, strontia, and magnesis. Neither lead acetate nor subacetate precipitate aqueous dextrose solutions, but lead oxide yields compounds similar to those with lime &c. (Brendeche, Ar. Ph. [2] 29, 84; v. Lippmann, Zuckerarten, p. 45; Péligot, J. pr. 15, 105; Franchimont, B. 12, 1939). Alkaline dextrose solutions dissolve copper hydroxide, and from these solutions soda or potash in proper proportions precipitates compounds of copper oxide and dextrose of varying composition (Guignet, C. R. 109, 528; Worm-Müller a. Hagen, Pf. 22, 325; Fileti, B. 8, 441; Salkowski, B. 12, 704). The compound C₆H₁₂O₈·22nO.3H₁O is formed by adding an alcoholic solution of dextrose to an ammoniacal solution of zinc oxide (A. C. Chapman, C. J. 1889. 576). Dextrose forms amorphous compounds with nickel, chromium, and iron oxides (Chapman, C. J. 1891. 323).

Compounds with metallic salts. Dextrose forms well-defined crystalline compounds with sodium chloride and bromide; their formulæ are 2C₂H₁₂O₂.NaCl.H₁O, which crystallises from diabetic urine, C₂H₁₂O₃.NaCl, C₅H₁₂O₃.2NaCl, 2C₆H₁₂O₃.NaBr (Pasteur, A. Ch. [3] 31, 92; Erdmann a. Lehmann, J. pr. 13, 111; v. Lippmann, Zuckerarten, p. 45; Städeler, C. C. 1854. 930; Hönig a. Rosenfeld, B. 10, 872; Stenhouse,

A. 129, 286).

Compounds with cyanogen. By digesting an aqueous solution of dextrose with hydrocyanic acid solution, the following reaction takes place: $C_6H_{12}O_8 + HCN + 2H_2O = C_7H_{13}O_8NH$, (Kiliani, B. 19, 767). To prepare this compound Kiliani gives the following directions: 100 g. crystalline dextrose are dissolved in 30 g. water, and an equivalent quantity of 60 p.c. hydrocyanic acid is added and digested for six days at the ordinary temperature; after twenty-four hours' further digestion at 35°C. all smell of hydrocyanic acid had disappeared, and the liquid smelt of ammonia. The ammonium salt thus obtained is converted into a barium one by boiling with baryta, and the free acid obtained by removal of the barium by sulphuric acid. Fischer (A. 270, 64) dissolves 5 kilos. dextrose in 25 litres 3 p.c. hydrogen cyanide solution, adds 10 c.c. ammonia solution, and digests the solution at 25°C. for six days, boils with baryta (6.7 kilos.) dissolved in water (20 litres) until all the ammonia is expelled, the hot liquid acidified with sulphuric acid, and boiled to expel hydrogen cyanide, neutralised with baryta. and filtered. The filtrate is concentrated. This syrup contains the lactones of a-heptonic acid and B-heptonic acid. After standing some weeks nearly the whole of the a-lactone will have crystallised out; the mass is triturated with alcohol of 80 p.c.; the filtrate yields a further crop of a-lactone, and the mother-liquor contains the B-lactone. This may be obtained by neutralising with brucine; the brucine 8-heptonate crystallises out, and is purified by recrystallisation; the brucine may be separated by precipitation with baryta, and the barium salt decomposed by sulphuric acid.

a-Glucohepto-lactone forms rhombic crystals readily soluble in water, and has $\{a\}_b = -55^\circ 3$; boiled with concentrated hydriodic acid it yields a heptolactone, b.p. $216^\circ - 230^\circ$ at 717 mm., with partial decomposition. About an equal quantity

of rormal heptoic acid is also produced (Kiliani, B. 19, 1128). By digestion with nitric acid S.G. 1·2 at 40° for 24 hours, a-glucoheptoic acid is oxidised to normal penta-oxy-pimelic acid (Kiliani, B. 19, 1916); this melts at 143°, is easily soluble in water, difficultly in alcohol, and soluble in ether. a-Gluco-heptonic acid yields a hydrazide C.H₁₁O,N₂H₂O₆H, m.p. 171°-179° (Fischer, B. 22, 2732).

β-Gluco-heptonic lactone crystallises in delicate needles, m.p. 151°-152°, reduces Fehling's solution, and is very soluble in water; its sp. rot. power is [α]₁₀₀° = -67·7°. Its phenylhydrazide C,H₁₃O,N,H₂Ph crystallises from alcohol in yellowish leaflets, and melts at 150°-152°. Heated with pyridine (4 lactone, 4 pyridine, and 20 water) in a sealed tube for three hours it is

converted into the a- acid.

Hydrazine compounds. A concentrated solution of dextrose yields, with phenylhydrazine, dextrose phenylhydrazine C₁₂H₁₈N₂O₅; this forms fine crystals, melting at 144°-145°. When heated with an aqueous solution of phenylhydrazine, hydrochloride, and sodium acetate on the waterbath, yellow crystals of phenylglucosazone $C_{18}H_{22}N_1O_4$ are formed (Fischer, B. 20, 824). Phenylglucosazone can be prepared by heating on the water bath 1 pt. dextrose, 2 pts. phenylhydrazine hydrochloride, 3 pts. sodium acetate, and 20 pts. water; after 10-15 minutes' heating the separation of osazone commences, and after $1\frac{1}{3}$ hours the precipitate amounts to about 85-90 p.c. of the weight of dextrose taken. It is purified by recrystallisation from alcohol. Another method which gives satisfactory results is to heat a mixture containing 1 g. sugar in 100 c.c. water and 5 c.c. of a solution containing in 1 litre 400 g. phenylhydrazine and 400 g. glacial acetic acid. According to Maquenne's (C. R. 112, 799) numbers, the yield is low, but by increasing the strength of the sugar solution and keeping up the quantity of the phenylhydrazine acetate solution in proportion, it is materially increased. It is insoluble in water; not very soluble in cold, but fairly easily in boiling alcohol. It melts at 204°-205° with decomposition, and so in m.p. determinations it is important that the heating be done as quickly as possible. It reduces Fehling's solution, and is leworotatory (Fischer, B. 17, 579). It dissolves in cold fuming hydrochloric acid, with a dark-red colouration, the osazone group O.H., HN.; C:C:N., HC. H., being thereby converted into the group .CO.CO. This reaction is common to all the osazones of the sugars, and Fischer (B. 21, 2631) has called the compounds thus obtained -osones. Dextrosone reduces Fehling's solution on boiling, and does not ferment with yeast; with phenylhydrazine acetate it again yields phenylglucosazone. The osazone is reduced by zinc and acetic acid to iso-glucosamine, which yields lævulose by treatment with nitrous acid (Fischer, B. 19, 1920; 20, 2569). The osone yields compounds with methyl phenylhydrazine and ortho-diamines (Fischer, B. 22, 87). By proceeding in the same way o-tolyldettrosazone C₂₂H₂₅N₁O, m.p. 201° and p-tolyl-dextrosazone C₂₂H₂₂N₁O, have been prepared (Raschen, A. 239, 229). Diphenyl-hydrazine combines with the sugars in alcohol solution; sparingly soluble crystalline hydrazones are

formed, which are resolved into their constituents by concentrated hydrochloric acid. The dextrose compound $C_aH_{12}O_sN_a(C_aH_a)_2$ melts at 161° (Stahel, A. 258, 242). Roder (A. 236, 229) has prepared phenyldextrosazone carboxylic acid.

Compounds with aromatic amines. trose - o - diamido - benzene C_sH₁(NH)₂.C_sH₁₀O₅ and anhydro - dextrose - o - diamido - benzene $C_{\mu}H_{\mu}N_{\sigma}C_{\mu}H_{\mu\sigma}O_{\mu} + 2H_{\mu}O$ are formed by the interaction of dextrose and o-phenylene-diamine in acid solution. Di-dextrose-o-diamido-benzene is obtained when the reaction takes place in neutral solution. They are all crystalline bodies, soluble in water, and having a bitter taste. The first one does not reduce Fehling's solution, the last two do (Griess a. Harrow, B. 20, 281 and 2205); o-tolylene-diamine gives a similar compound (Hinsberg, B. 20, 495). Dextrose-ydiamido-benzoic acid is obtained by mixing boiling aqueous solutions of dextrose and γ-diamidobenzoic acid (Griess a. Harrow, l.c.). aniline dextrose forms a crystalline anilide m.p. 147° (Schiff, A. 154, 30; Sorokin, B. 19, 513; J. R. 1887, 377). Dextrose forms compounds with aldehyde, acetone, benzaldehyde, chloral, &c. (Schiff, A. 244, 19; Heffter, B. 22, 1050).

Dextrose-oxim $C_6H_{13}O_6N$ is formed by the combination of dextrose and hydroxylamine. It forms colourless, microscopic crystals, m.p. $136^\circ-137^\circ$; very soluble in water, sparingly soluble in alcohol, and insoluble in ether. It reduces Fehling, and is levorotatory, having $[a]_{1000} = -2 \cdot 2^\circ$ (Jacobi. 24, 696).

[a]_{Dmo} = $-2\cdot2^\circ$ (Jacobi, B. 24, 696).

On warming an alkaline solution of dextrose with pieric acid a blood-red colour is produced (Braun, Fr. 4, 185). It to crystallised diazobenzene suiphonic acid be added soda, dextrose solution, and a little sodium-amalgam, a red colouration is produced in a short time (Penzold a. Fischer, B. 16, 657).

Many aromatic alcohols give a colouration with dextrose and other carbohydrates in the presence of sulphuric acid. If two drops of a 15-20 p.c. alcoholic solution of (a) naphthol be added to a dextrose solution, and one part of concentrated sulphuric acid, a violet colouration will be produced, changing to bluish violet.

Optical isomerides of glucose, gluconic acid and saccharic acid (E. Fischer, B. 23, 2611).

I-Gluconic acid. I-Mannonic acid can be converted into l-gluconic acid by heating with quinoline, but it is most conveniently prepared from arabinose by treatment with hydrogen cyanide and baryta (Kiliani, B. 19, 3029); I-mannonic and l-gluconic acids are formed simultaneously. The greater portion of the I-mannonic acid may be separated as lactone, and the remainder may be separated from the I-gluconic acid by crystallising out the calcium I-gluconate.

i-Gluconic acid is obtained by mixing the l- and d- acids, or from i-mannonic acid by quinoline.

l-Glucose is formed by reducing l-gluconic lactone with sodium-amalgam; it resembles dextrose closely, but does not ferment with yeas; $[a]_{\rm b} = -51.4^{\circ}$; its derivatives also resemble the corresponding ones of dextrose very closely.

i-Glucose is prepared by mixing i- and d-glucose or reducing i-gluconic acid.

I-Secenaric acid is prepared by exidising I-gluconic acid with nitric acid.

i-Saccharic acid is prepared by oxidising i-gluconic acid or by mixing l- and d- saccharic acid.

Lævulose. d-Fructose, lævoglucose, fruit sugar; $C_aH_{12}O_a$.

Occurrence.—Lævulose is widely distributed in the vegetable kingdom, being found, together with dextrose, in many parts of plants, in honey, &c. (v. Dextrose).

&c. (v. Dextrose).
Formation.—The following carbohydrates
yield levulose, either alone or accompanied by
other sugars, when acted on by dilute acids:

Cane sugar yields dextrose and lævulose. Raffinose yields lævulose, galactose, and dextrose.

Inulin yields lævulose.

Irisin (O. Wallach, A. 234, 364), lævulan (v. Lippmann, B. 14, 1509), triticin (Reidemeister, C. C. 1880, 808), scillin (Riche a. Remont, J. Ph. [5] 2, 291), sinistrin (Schmiedeberg, B. 12, 704), lævulin or synanthrose (Dieck a. Tollens, A. 198, 228; Ville a. Joulie, Bl. [2] 7, 262; Popp, A. 156, 185; Müntz, C. R. 227, 679), and inuloid (Popp, A. 156, 190) also yield lævulose. Lævulose is formed by the oxidation of mannitol (Cotton, Bl. [2] 33, 546; Gorup-Besanez, A. 118, 273; Bodenbender, Zeit. d. Ver. 14, 812; Renard, A. Ch. [5] 17, 316), by the fermentation of mannitol by B. aceti and B. xylinum (A. J. Brown, C. J. 1886, 184; 1887, 641); from phenylglucosazone by reduction to isoglucosamine, and thegee by the action of sodium nitrite; from glucosone by reduction with zinc and acetic acid (Fischer, B. 22, 87, 2566).

Preparation.-Inulin is heated with very weak sulphuric acid for some hours, after which the sulphuric acid is carefully precipitated by baryta water and the filtrate decolourised by charcoal and evaporated on the water bath to a This is treated several times with absolute alcohol, which removes the water, and the syrup which remains put on one side for some time in a closed flask, when fine needles make their appearance, and in time the whole solidifies (Jungfleisch a. Lefranc, C. R. 93, 547; also Crookewitt, A. 45, 184; Krusemann, A. 282, 26; Wohl, B. 23, 2084). A 10 p.c. solution of cane sugar is carefully inverted with hydrochloric scid (20 c.c. to a litre of solution) at 60°. The solution is cooled to -5° , 6 g. of slaked lime added for each 10 g. sugar, the temperature allowed to rise to 2°, and the line lavulose carefully pressed from the rest of the solution and washed repeatedly with water. It is finally suspended in water, decomposed by oxalic acid, and the filtered solution evaporated in vacuo to a syrup which, when treated with absolute alcohol as above described, yields crystals of lævulose (Girard, Bl. [2] 33, 154; Dubrunfaut, C. R. 42, 901; 69, 438).

Formula and synthesis. See general part. Properties.—Lævulose forms colourless, fine, shining needles, belonging to the rhombic system, the axial ratio is a:b:c=0.80067:1:0.90674; they are slightly biaxial as regards their action on polarised light; they have a composition corresponding to the formula C_sH₁₂O_s, melt at 95°, and lose water at 100°. According to Hönig a. Jesser (M. 9, 562), the crystals con-

tain water of crystallisation and have a formula 2C,H12O,H2O. If free from alcohol they are not deliquescent in the air (Hönig a. Schubert, M. 8, 529; Jungfleisch a. Lefranc, l.c.). The sugar is almost insoluble in cold absolute alcohol. and soluble in a boiling mixture of alcohol and ether (Diech a. Tollens, A. 198, 228). With regard to the specific rotatory power of levulose there are many and varied statements; all those based on the factors of unpurified solutions obtained by the inversion of inulin or cane sugar are worthless, as lævulose is extremely easily decomposed by acids (Jungfleisch a. Grimbert, C. R. 108, 144), and many apparent discre-pancies may be explained by the fact that the optical activity varies very much with the temperature. Jungsleisch a. Grimbert (C. R. 107, 390) found for crystallised lævulose $[a]_D = -101.38^{\circ} - 0.56t + 0.108 (p-10)$, where t is the temperature and p the weight of levulose This formula holds for in 100 c.c. solution. temperature 0°-40° and for concentrations betemperature 0'-40° and for concentrations below 40 p.c. The $[a]_j = -108^\circ$ (c=10 g. sugar in 100 c.c.), calculated from $[a]_j = -24.5$ for invert sugars, and $[a]_j = +58.5$ for dextrose agree very well with the numbers of Jungfleisch a. Grimbert. Hönig a. Jesser (M. 9, 562) give $[\alpha]_1 = -111.38$, c 10, $t = 20^\circ$ for a carefully crystallised preparation. Herzfeld a. Winter (B. 19, 390) give for 20 p.c. solution at 20° [a]_D = -71.4° ; but these determinations cannot be for the pure body. Freshly-prepared solutions of crystallised lævulose have a greater sp. rot. power than after standing a short time; Parcus a. Tollens (A. 257, 160) found for a 10 p.c. solution at 20° observed in a 200 mm. tube, $[a]_p = -104.02^\circ$ six minutes after commencing solution, which sank to a constant value $[a]_D = -92.25^{\circ}$ in 35 minutes. This cannot have been pure lævulose. K = 100; but Soxhlet makes it 92-93 (J. O'Sullivan, C. J. 1892, 408).

Action of heat and acids. Lævulose is exceedingly easily decomposed by heat and acids. Its aqueous solutions colour exceedingly quickly if heated for any length of time. Wohl (B. 23, 2084) found that by the action of minute quantities of acid on a hot concentrated solution of lævulose, a dextrin-like body was produced which was reconverted into levulose by boiling with dilute acids. This instability accounts for the many different numbers which have been given for the sp. rot. power and for the fact that the opt. act. of invert sugar does not in all cases correspond with that of a mixture of pure lævulose and dextrose in equal quantities. On boiling with dilute sulphuric or hydrochloric acids, acetopropionic, formic, and other acids are produced Jungfleisch a. Grimbert, C. R. 108, 144; Grote a. Tollens, A. 175, 181; Sieben, Zeitschr. d.

Ver. 34, 237; Conrad a. Guthzeit, B. 19, 2569).

Action of alkalis. Alkalis quickly decompose lavulose, especially on warming; caustic sods and baryta yield lactic acid among other products (Sorokin, J. R. 1885, 368). Sodium lavulose C.H., NaO. is produced by acting on an alcoholic solution of lavulose with sodium ethylate (Hönig a. Rosenfeld, B. 12, 45). Lime yields a compound C.H.,O.,CaO.H.,O., which is soluble in 137 parts cold water (E. Péligot, C. R. 90, 153; Herzfeld a. Winter, B. 19, 390); and 2(C.H.,O.)3CaO, which torms needles soly.

ble in 338 parts cold water (Dubrunfaut, A. Ch. [8] 21, 169). Similar compounds are formed with potash, baryta, lead oxide, and bismuth oxide (Herzfeld a. Winter, B. 9, 890, and v. Lippmann, Zuckerarten, p. 68). If a solution of levulose be boiled with lime, saccharin is formed (Scheibler, B. 13, 2212).

Reduction.—Lævulose in alkaline solution is reduced by nascent hydrogen to mannitol, and more easily than dextrose (Scheibler, B. 16, 8010; H. Krusemann, B. 9, 1465; Herzfeld, A. 244, 274). Fischer (B. 23, 3634) finds that equal parts of mannitol and sorbitol are produced.

Oxidation .- Mercuric oxide and baryta boiled with an aqueous solution of levulose yield formic, glycollic and normal trioxybutyric acid (Börnstein a. Herzfeld, B. 18, 3353). Bromine water in the same way yields normal trioxybutyric acid (Hönig, B. 19, 171; Herzfeld a. Winter, B. 19, 390; C. C. 1886, 271). Lævulose by oxidation always yields an acid containing less carbon atoms than itself (Herzfeld a. Börnstein, C. C. 1886, 187; Herzfeld a. Winter, C. C. 1886, 271; B. 19, 390). Chlorine and bromine with silver oxide oxidise lævulose to glycollic acid (Hlasiwetz a. Habermann, A. 155, 130; Kiliani, A. 205, 175). Nitric acid yields oxalic acid, tartaric acid, glycollic acid, formic acid, a little saccharic acid, malic acid, acetic acid, and racemic acid (Dragendorf, Materialien zu einer Monographie des Inulins; Kiliani, A. 205, 162; Hornemann, J. pr. 89, 283).

Fermentation.-Lavulose ferments easily with yeast, with formation of alcohol and carbonic acid &c., but rather slower than dextrose, so that towards the end of a fermentation of invert sugar the solution is always levorotatory (Bourquelot, A. Ch. [6] 9, 245; C. R. 101, 958; C. R. 100, 1404 and 1466; Maumeno, C. R. 100, 1505; 101, 695; Leplay, C. R. 101, 479; Gourgon a. Dubourg, C. R. 110, 865).

Compounds with acids. Chlorosulphonic acid gives a tetra-sulphate (Claesson, J. pr. [2] 20, 1 a. 18). Acetyl chlorido yields an aceto-chlorhydrin (Colley a. Wachowitsch, B. 13, 2390; Bl. [2] 34, 326). With acetic anhydride, acetic acid, and zinc chloride levulose yields pentacetyl levulose (Erwig a. Koenigs, B. 23, 672). Benzoyl chloride yields pentabenzoyl lævulose, m.p. 85° (Skraup, M. 10, 389).

Compounds with bases. See Action of alkalis above.

Compounds with metallic salts. Compounds with potassium or sodium chloride have not been described. A compound with lead chloride is known (Herzfeld a. Winter, B. 19, 390).

Compounds with cyanogen. By treatment with strong hydrocyanic acid, lævulose yields a cyanhydrin $C_1H_{13}O_4N$, this crystallises from water in tabular monoclinic crystals, m.p. 110°-115°, and has a slight dextrorotatory power; fuming hydrochloric acid converts it into the lactone of fructoheptonic acid C,H12O,, and this, heated with hydriodic acid and phosphorus, yields a heptolactone $C_1H_{12}O_2$, b.p. 220°, which does not solidify in a freezing mixture. When the lactone is further treated with hydriodic acid and phosphorus an acid is obtained boiling at 210°. which is identical with methyl-butyl-acetic acid as synthetically prepared (Kiliani, B. 18, Vol. IV. 8966; 19, 221 and 1914; Kiliani a. Düll, B. 23, 449). Tetra-oxy-butane-tri-carboxylic acid COOH.(CH.OH), C(OH)(COOH); is obtained by oxidising fructoheptonic acid by nitric acid (Düll, B. 24, 348).

Hydrazine compounds. Lævulose yields an esazone which appears to be identical with, and is prepared in the same manner as, dextrose

osazone (q.v.).

Anilides. By heating an aqueous solution of lavulose with aniline, an anilide is formed nelt at 147° with partial decomposition (Sorokin, B. 19, 513; J. R. 1886, 129; 1887, 877). With hydroxylamine lavulose combines to form lævulosoxim (Wohl, B. 24, 993). It strongly resembles dextrosoxim in appearance, m.p. 1180 it is levorotatory, and reduces ammoniacal silver solutions on warming, whilst dextrosoxim does so in the cold.

Galactose. Lactose. CaHiaOa. does not occur in nature.

Formation.—By the action of dilute acids on many carbohydrates and similar substances of vegetable and animal origin. Lactose yields dextrose and galactose (Pasteur, C. R. 42, 347; Fudakowski, B. 9, 42; C. C. 1877, 6). Raffinose yields levulose, galactose, and dextrose. a-Galactin, B-galactin, paragalactin, lactosin, agar-agar, carragheen moss, plum gum, peach gum, gum arabic, gedda gum, and many other similar vegetable substances, yield galactose amongst other products of their hydrolysis (Müntz, Bl. [2] 37, 409; A. Ch. [6] 10, 566; C. R. 94, 453; 102, 624, 681; A. Meyer, B. 17, 690; Bauer, J. pr. [2] 30, 375; L. V. 1888, 33 a. 214; Hädicke, Bauer a. Tollens, A. 238, 302; Kiliani, B. 13, 2304; 15, 36; v. Lippmann, B. 17, 2238; Scheibler, B. 1, 58; 6, 612; 17, 1729; O'Sullivan, C. J. 1884, 41; 1391, 1029; Hädicke a. Tollens, A. 238, 308; Schulze a. Steiger, B. 19, 827;
20, 290; L. V. 36, 391; Schulze, B. 25, 2213;
Maxwell, Am. C. J. 12, 51 a. 265; v. Lippmann, Deutsche Zuckerind., 1887, 455; B. 20, 1001; Stone, Am. 12, 435). Galactose is also produced by the long-continued action of dilute sulphuric acid on certain nitrogenised constituents of the brain (Thudichum, Ann. of Chem. Med. [2] 209: Thierfelder, Z. P. C. 14, 209; Brown a. Morris, C. J. 1890, 57). This sugar was called by the discoverer cerebrose; B. a. M. proved it to be galactose.

Preparation .- A solution of lactose (milksugar) containing in every 100 c.c. 25 g. dry lactose; 2 to 3 grams H.SO, is digested in a flask on the water-bath for 25 to 3 hours, the water being kept boiling all the time and care being taken by continual shaking of the flask to avoid colouring. The acid is, on cooling the solution, carefully neutralised with baryta water and the BaSO, separated by filtration. On evaporating the filtrate to a strong syrup in a vacuum solidification takes place in a short time. The solid crystallised mass is digested several times with dry methyl alcohol; this dissolves out the dextrose and other products of the action of the acid on lactose and the hydrolysed sugars, and leaves galactose as a white crystalline powder. This is dissolved in the least possible quantity of boiling water, again allowed to solidify, and again treated with boiling methyl alcohol. If

the whole of the lactose hydrolysed, and it ! generally is under the conditions indicated, the residue is white, nearly pure, galactose. It can be rendered pure by recrystallisation from water. If the crystals are allowed to form slowly from solutions not too concentrated they are distinct and well-defined (Rendell, N. Z. 4, 163; Soxhlet, J. pr. 2, 21, 269). The sugar can also be prepared from certain gums of the arabin group. For this purpose the most suitable are those having a lavorotatory power and yielding the larger percentage of mucic acid on oxidation with nitric acid. The dextro-gums also yield the sugar, but in less quantity (O'Sullivan. C. J. 1884, 41; 1891, 1029). A solution of the gum selected—gum arabic, Turkey, Levantine or East India gum - is made containing about equal weights of water and gum; this is heated in a flask in a water-bath as high as the boiling bath will take it, and 5 grams H,SO, diluted to 15 c.c. added for every 100 c.c. of the gum solution employed. The mixture is digested for 30 to 35 minutes, then rapidly cooled, and alcohol, S. G. 0.83, added as long as a pp. is produced. This pp. is again dissolved in water, and again ppd. One or two fepetitions of this process frees the pp. from arabinose. A solution of the same strength as that above described for the original gum is then made of the pp. and heated as high as the boiling water of a water-bath will take it, and then for every 100 c.c. of the solution 5 grams H,SO, diluted to 15 c.c. added. At the end of about 8 hours' digestion the solution is cooled, carefully neutralised with baryta water, and alcohol, 0.82, added as long as a pp. is thrown out. The alcoholic solution becomes clear on standing; it contains galactose, and on concentration in a vacuum yields crystals of the body in a fairly pure state. They may be completely purified by washing with methyl alcohol, recrystallising the residue from ethyl alcohol, and finally from water.

Formula and synthesis. See general part.

Properties.—Galactose crystallises in hexagonal plates, m.p. $163^\circ-164^\circ$ (after drying at 100°) (E. Bourquelot, J. Ph. [5] 13, 51), or, according to v. Lippmann (B. 18, 3335), in microscopic six-cornered prisms and needles, m.p. 168° . Galactose is easily soluble in water, almost insoluble in methyl alcohol. Solutions of galactose rotate a ray of polarised light to the right, the specific rotatory power for the D line being given by the formula $[a]_{\mathbf{p}} = 83^\circ-883 + 0^\circ-0785P - 0^\circ-209^\circ$ (Meissl, J. pr. [2] 22, 97); this formula agrees well with numbers found by other observers. Freshly-prepared solutions exhibit the phenomenon of bi-rotation (Pasteur, J. pr. 68, 428). Parcus a. Tollens (A. 257, 160) observed an angle of $[a]_{\mathbf{p}} = 117^\circ-48^\circ$ in a 10 p.c. solution at 20° , 7 minutes after commencing solution. K=100, and varies slightly with the conditions of determination.

Action of acids. By prolonged heating with dilute acids, galactose yields aceto-propionic and formic acids (Kent a. Tollens, A. 227, 228; B. 17, 668; Conrad a. Guthzeit, B. 18, 2905; sulphuric acid and chloro-sulphuric acid yield galactose-sulphuric acids (Hönig a. Schubert, M. 7, 455; Classon, J. m. 21, 20 a, 180.

M. 7, 455; Claësson, J. pr. [2] 20 a. 18).

Action of alkalis. Alkalis colour galactose yellow; the action of milk of lime produces saccharin (Cuisinier, v. Lippmann, Zuckerarten).

Fusion with KHO gives rise to acetic and exalic acids.

Reduction. — By reduction with sodiumamalgam, galactose yields dulcitol and other alcohols (Bouchardat, A. Ch. [4] 27, 79).

Oxidation.—Bromine oxidises galactose to galactonic acid (lactonic acid) C₆H₁₂O₇, isomeric with gluconic acid (Hlasiwetz a. Habermann, A. 122, 96; Kiliani, B. 13, 2307; 18, 1551; Bauer, J. pr. [2] 30, 379); which when heated loses 1 mol. water, and is converted into the lactone; it yields with phenylhydrazine a hydrazide which melts at 200°-205° with decomposition (Fischer a. Passmore, B. 22, 2731). Nitric acid oxidises galactose to mucic acid, isomeric with saccharic acid. As mucic acid is only slightly soluble in water, the yield of mucic acid, which is normally 75 to 78 p.c., is sometimes made use of for the estimation of galactose; but the yield varies considerably with the condition of experiment (Pasteur, C. R. 42, 349; Kent a. Tollens, A. Ch. 227, 228). Neutral or alkaline solutions of cupric hydroxide are reduced by galactose; carbonic, formic, glycollic, and lactic acids are produced (Habermann a. Hönig, M. 5, 208).

Fermentation.—According to Kiliani (B. 13, 2305) and Koch (B. 20, Ref. 145), galactose does not ferment with yeast, whilst v. Lippmann (B. 17, 2238; 20, 1001), Bourquelot (C. R. 106, 283), and Pasteur find that it does ferment. Stone a. Tollens (A. 249, 257; B. 21, 1572) find that it ferments with beer yeast as well as with Mucor racemosus, but slower than dextrose. Certain bacteria yield lactic acid (Pranzmovaski a. v.

Tieghem, B. 12, 2087).

Compounds.—Galactose yields a crystalline compound with sodium chloride (Fudakowsky, Bl. [2] 30, 433). With a solution of baryta in methyl alcohol, galactose yields the compound $(C_eH_{11}O_e)_e$ Ba. BaO (Fudakowsky, l.c.). With acetic anhydride, a pentacetate is produced C_sH₂O(C_sH₃O_s), m.p. 62°-66° (Fudakowsky). According to Erwig a. Koenigs (B. 22, 2207) this body melts at 142°, crystallises in rhombic prisms, reduces Fehling's solution, is dextrorotatory, and differs in all its properties from Fudakowsky's galactose pentacetate. With aniline, galactose forms an anilide, crystallising in long triclinic prisms, and levorotatory (Sorokin, J. R. 1887, 377; B. 19, 298). With hydroxylamine, galactose yields the oxim C₆H₁₂NO₆, the crystals melt at 175°-176°, and are easily soluble in water and weak alcohol (Rischbieth, B. 20, 2673). With ortho-diamido-benzene, galactose yields galactose-o-diamido-benzene C_eH₄(NH)₂·C_eH₁₀O₃, melting at 246° with decomposition. Galactose-y-diamido-benzoic POSITION. GREACIOSE-7-Hammo-serizoro Local COOH.C₀H₃(NH)₂·C₀H₁₀O₃+H₂O crystallises in needles (Griess a. Harrow, B. 20, 3111). With hydrocyanic acid, galactose yields galactohep-tonamide C,H₁₈NO,, m.p. 194°; it is converted into the barium salt of galactoheptonic acid C,H,O, by digesting with baryta. The free acid melts at 145° and orystallises in slender needles; it is reduced by hydriodic acid and phosphorus to the lactone of Lormal γ-oxyheptoic acid (b.p. 231°) and a very small quantity of normal heptoic acid (Maquenne, C. R. 106, 286; Kiliani, B. 21, 915; 22, 521 a. 1385). With phenylhydrazine, galactose forms galactose-phenylhydrazide, crystallising in colourless

needles, m.p. 158°, and galactose-osazone, m.p. 198°-194° (Fischer, B. 20, 821). Fischer's first determination of the melting-point (B. 17, 579) was 182°, Scheibler (B. 17, 1731) gave 171°, and other observers have given lower numbers; this may be accounted for by the fact that unless the osazone be heated up very quickly it decom-poses before it fuses. By the action of hydrochloric acid it yields galactose-osone (Fischer, B. 22, 87). Galactose also yields a diphenylhydrazide, m.p. 157° (Stahel, A. 258, 212). Galactose forms a penta-benzoate C.H.O(C.H.O.)

Suppose the supplier of

m.p. 165° (Skraup, M. 10, 389).

Sorbose. Sorbinose C₈H₁₂O₆. Sorbose is obtained from the juice of the mountain ash after allowing it to stand for some time. It is doubtful if it exists in the fresh juice as a free sugar, but it is probably formed by the decomposition of a glucoside (Pelouze, A. Ch. [3] 35, 222; Boussingault, C. R. 74, 939; Delffs, B. 4, 799; Byschl, J. pr. 62, 504; Freund, M. 11, 560). The expressed juice of the unripe berries of the mountain ash is allowed to ferment for eight or ten months, the clear solution is filtered from the organisms by which the fermentation was effected, and evaporated to a syrup, when the scrbose crystallises out on standing. It forms colourless rhombic crystals easily soluble in water. Its solutions are laworotatory: for 10 p.c. solution, $[\alpha]_D = -43.4^{\circ}$ (Wehmer a. Tollens, B. 19, 708). It is oxidised by chlorine and silver oxide to glycollic acid; it behaves with bromine water like lavulose, being practically unaltered (Kiliani a. Scheibler, B. 21, 3276); nitric acid oxidises it to oxalic, aposorbic and tartaric acids. By more careful oxidation with HNO. Kiliani a. Scheibler (l.c.) obtained trioxy-glutaric acid. Copper hydrate oxidises it to carbonic and formic acids and other bodies, amongst which is possibly glyceric acid (Dessaignes, J. pr. 89, 313; Hlasiwetz a. Habermann, A. 155, 129; Habermann a. Hönig, M. 5, 208). Hydriodic acid reduces it to hexyl iodide (Kiliani a. Scheibler, l.c.). It reduces Fehling's solution, and is coloured yellow by alkalis. Sorbose ferments slowly with beer yeast (Stone a. Tollens, A. 249, 257). By prolonged heating with dilute acids it is decomposed, yielding, amongst other bodies, lævulinic acid (Wehmer a. Tollens, l.c.). With phenyl-hydrazine it yields an osazone $C_{18}H_{22}N_4O_4$, m.p. 164° , which is almost insol in water, but fairly easily soluble in alcohol, from which it crystallises in fine microscopic needles (Fischer a. Tafel, B. 19, 1920; 20, 217 and 2566; Fischer, B. 20, 828).

Mannose. Seminose C.H 12O. This sugar

does not occur free in nature.

Formation .- It is obtained by the action of dilute sulphuric acid on the so-called reserve cellulose (Reiss, B. 22,609, 3218) and on salep juice (Tollens a. Gans, A. 249, 256), and by the oxidation of mannitol (Fischer a. Hirschberger, B. 21, 1805; 22, 1155 a. 3218; Carlet, J. 1860. 250; Gorup-Besanez, A.118, 257; Dafert, B. 17,

227).

Preparation. — Sifted ivory nut shavings (1 pt.) are digested with 6 p.c. hydrochloric acid (2 pts.) for six hours on the water-bath, filtered hot, and the residue pressed and extracted with water. The brown solution contains the sugar. It may be obtained as hydraside by adding phenyl-hydrazine acetate, and this is decomposed by hydrochloric acid with reproduction of the sugar (Fischer a. Hirschberger, B. 22, 365 a. 3218).

Properties.—Mannose is precipitated from its alcoholic solution by ether; the syrup, on keeping under absolute alcohol, solidifies to a hard colourless mass which shows no sign of crystalline structure. Its solutions are dextrorotatory, $[\alpha]_D = 13.0^{\circ}$ approx.; they are reduced by Fehling's solution, 1 c.c. of this solution being reduced by 4.307 mgm. mannose, i.e. K = 110°-112°. It is fermented by yeast.

Reduction .- Mannose is reduced by sodiam-

amalgam to mannitol.

Oxidation.- Mannose is oxidised by bromine to mannonic acid, the lactone of which (CaH10Os) crystallises in colourless needles, readily soluble in water and less in alcohol; it is dextrorotatory in aqueous solutions, $[a]_D = 53.8^\circ$, and forms a phenylhydrazide $C_{12}H_{18}N_2O_8$, m.p. 214° _ 216°. Its optical isomeride, l-mannonic acid, is obtained by the nitrile reaction from arabinose. Oxidised with nitric acid, manno-saccharic acid is obtained (Easterfield, C. J. 1891, 306; Fischer, B. 24, 539). It crystallises in colourless needles. m.p. 180° - 190° , and $[\alpha]_{p} = 201.8^{\circ}$. With ammonia it yields a monamide, and with phenylhydrazine a mono- and di-phenylhydrazide. Kiliani's metasuccharic acid is its optical isomeride (1-mannosaccharic acid) (Fischer, l.c.).

Action of acids. Hot hydrochloric acid has little action on mannose, but if the heating be continued for some time, humus substances are

formed.

Action of alkalis. Alcoholic potash precipitates a flocculent hygroscopic substance

from solutions of the sugar.

Compounds. - Lead acetate and ammonia produce a precipitate which becomes yellow on keeping. With phenylhydrazine it yields a sparingly soluble hydrazide, C₁₂H₁₈N₂O₃, crystallising in yellow slender prisms, m.p. 195°–200°, le vorotatory in dilute hydrochloric acid solution. By heating the hydrazide with excess of phenylhydrazine hydrochloride, sodium acetate, and water, it yields an osazone C18H22N,O4 crystallising in yellow needles, which is identical with phenylglucosazone. With di-phenyl-hydrazine it yields a di-phenyl hydrazide, m.p. 155°. With hydrocyanic acid it yields a compound which is easily decomposed, yielding mannose-heptonic acid; its lactone C.H.O. crystallises in needles, m.p. 148°-150°; by reduction with hydriodic acid normal heptoic acid is obtained. With hydroxylamine mannose yields an oxim C_eH₁₃O_eN, m.p. 184° (Reiss, *l.c.*; Fischer a. Hirschberger, B. 22, 1155). Aceto-chloro-mannose is obtained by the action of acetyl chloride (Fischer, l.c.).

Phlorose C_aH₁₂O_a. This has been shown to be identical with dextrose (Rennie, C. J. 887,

636; Fischer, B. 21, 988).

Crocose C₆H₁₂O₈. Kayser (B. 17, 2232) a. Rochleder a. Mayer (J. pr. 74, 1) obtained a dextrorotatory sugar by heating saffron (from Crocus electus or yellow shoots of Gardenia grandiflora) with dilute sulphuric acid. It forms rhombic crystals, which only reduce half as much copper oxide as dextrose. According to Fischer (B. 21, 988), it yields, with phenylhydrazine, an osazone identical with phenyl glucosazone,

Lokaose C.H. O. is obtained from lokao or Chinese green by boiling with dilute sulphuric acid, lokaonic acid yielding lokanic acid and lokaose $C_{42}H_{48}O_{27} = C_{38}H_{36}O_{21} + C_6H_{12}O_6$. Lokaose forms minute acicular crystals, and is distinguished from dextrose by being optically in-active and having a lower reducing power (K=50) (R. Kayser, B. 18, 3417).

Tabakose is said to exist in tobacco (Att-

field, Ph. 541).

Digitalose C.H., O, is obtained, together with dextrin, by the action of strong hydrochloric acid on digitalin; oxidised with bromine it yields digitalonic lactone C,H,O,; hence the formula of the sugar (Kiliani, Ar. Ph. 230, 250;

B. 25, 2116),

Aromatic sugar. Phenyltetrose (Fischer a. Stewart, B. 25, 2555). Cinnamaldehyde cyanhydrin, when dissolved in chloroform and bromine added, yields phenyl-dibromo-oxy-butyronitril CHPhBr.CHBr.CH(OH)CN; this when heated with hydrochloric acid yields phenylbromodioxybutyrolactone

CHPh CH, Br CH.OH, from which the acid CHPh.CHBr.CH(OH).COOH is easily obtained; on reduction this yields phenyltetrose OH.CHPh.CH(OH),CH(OH),COH. It yields a

phenylhydrazide, m.p. 154°. For Acrose, Formose, Glycerose, see Synthesis

of the Sugars.

CLASS II. The '-on' sugars.

(a) Dipentose. Arabinon, diarabinose, or arabinbiose C₁₀H₁₈O₉. A product of the partial hydrolysis of a series of gum acids. A 25 p.c. solution of any of the strongly rotating gum acids is heated to boiling, and 2 g. sulphuric acid for every 100 c.c. solution, previously diluted with 4 to 5 volumes water, added. At the end of 10 to 15 minutes' digestion the solution is quickly cooled and alcohol, sp.gr. '830, added as long as a precipitate forms. The clear alcoholic solution contains arabinon and arabinose, and some arabinon is taken down with the precipitate; and on again dissolving it in a little water and reprecipitating with alcohol, the arabinon often appears on the surface of the syrup in spherocrystals, and the alcoholic supernatant liquid contains it in quantity. It is easily soluble in water and methyl alcohol. Dilute ethyl alcohol also dissolves it, but absolute alcohol precipitates it as a syrup from a strong methyl alcohol solution. Ether also precipitates it. Its solutions are dextrorotatory, $[a]_D = +202^\circ$ (c. 6.466), there appears to be an increase with the concentration; it reduces Fehling's solution; K = 58 (K = 57.5 if2 mols. sugar reduce 9 mols. CuO). D=3.95. It tastes sweet, and is easily diffusible. acids hydrolyse it, the sole product being arabinose,

 $\mathbf{C_{10}H_{18}O_9 + H_2O} = 2\mathbf{C_5H_{10}O_8}$ Arabinon Arabinose

(O'Sullivan, C. J. 1890, 59).

(b) Dihexoses.

Cane sugar. Saccharon, sucrose C₁₂H₂₂O₁₁.
Occurrence. — Cane sugar is widely distributed throughout the vegetable kingdom, and is frequently accompanied by dextrose and lævulose. The most important sources are the sugar-cane (Saccharum officinarum); the sugar-beet (Beta vulgaris); the sugar-maple (Acer saccharinum) and Sorghum saccharatum (Girard, C. R. 102, 108; Centrbl. f. Agric. Ch. 1886. 683; Berthelot, C.R. 59, 583; A. Ch. [3] 55, 289; Buignet, A. Ch. [3] 61, 233; Maxwell, L. V. 36, 15, Am. 12, 265; Reports of the Department of Agriculture, Washington, No. 6; The Sugar Industry of the United States, by Wiley, 1885; The Literature of the Sugars, H. L. Roth, London, 1890; Gössmann, A. 104, 335; Hermbstädt, Gehlen's J. f. Ch. Ph. Min., 8, 589 (1809); Boier, Jahresb. f. Zuckerfabr. 5, 139; Balland, J. Ph. [4] 25, 97; Corenwinder, C. R. 83, 1238; A. v. Wachtel, B. C. 1880, 344; Stone, B. 23, 1406; Wiley, C. N. 51, 88; Ann. Agronom. 11, 392; Schulze a. Seliwanoff, L. V. 1887. 403; Washburn a. Tollens, B. 22, 1047; Stingl a. Morawski, M. 7, 176; 8, 82; Déon, Bl. [2] 32, 125; Reali, G. 17, 325; Schulze, L. V. 1887, 403, 408; v. also the references under the heading Dextrose. Occurrence, and many others throughout the range of chemical literature)

Formation.—Icery (A. Ch. [4] 5, 350) and Jackson (C. R. 46, 55) found that in the early period of vegetation of many plants, invert sugar only occurs, and that cane sugar is formed later. Leplay (C. R. 46, 444) confirms this observation in the case of sugar-cane. Barley contains from 0.8 to 1.6 p.c. cane sugar, whereas germinated barley (malt) contains from 2.8 to 6.0 p.c. cans sugar; the starch of the endosperm being converted into cane sugar for the use of the growing plant (Kuhnemann, B. 8, 202, 387; Kjeldahl, Res. du C. R. des Travaux du Lab. de Carlsberg, 1881, 189; O'Sullivan, C. J. 1886, 58). Brown a. Morris (C. J. 1890, 516) found that the cane sugar of germinated barley was chiefly localised in the embryo, whilst maltose appears in the endosperm; they consider that starch is first converted by diastase into maltose in the endosperm, and then, being transferred to the embryo, is converted into cane sugar for the purpose of growth. Colley a. Vakovitch (Bl. [2] 34, 326) may have obtained cane sugar by acting on barium lævulosate with acetochlorhydrose, but the evidence is not satisfactory. Aubert a. Giraud (D. P. J. 257, 298) state that by passing an electric current through acidified starch-paste at 100°C. cane sugar may be manufactured (?).

Preparation .- (For the commercial preparation of cane sugar see Thorpe's DICTIONARY OF APPLIED CHEMISTRY.) The best samples of commercial cane sugar consist of almost the pure sugar. Dry, clean, glassy sugar-candy is sufficiently pure for most purposes. Absolutely pure saccharon may be obtained by careful crystallisation from warm aqueous solutions; or a cold, clear saturated solution made with carefully-purified distilled water is mixed with an equal volume of purified ethyl alcohol, S.G. 820, with continual stirring. On standing, saccharon crystallises out in pure glassy crystals.

Properties .- Cane sugar forms fine large monoclinic hemihedral crystals, S.G. $\frac{17.5}{17.5}$ 1.58047 (Schröder, B. 12, 562; Gerlach, D. P. J. 172, 31 and 286; Joule a. Playfair, C. J. 1, 130), which do not contain water of crystallisation. It is easily soluble in water; 100 parts of a solution saturated at 0° contain 65.0 pts. saccharon, at 20° 67 pts., and at 40° 75.8 pts. (Scheibler,

2. 7. 22, 255). A large number of figures have been given to represent the relation between the quantity of sugar in solution and the specific gravity thereof (v. Lippmann's Zuckerarten; Brown a. Heron, C. J. 1879, 644; Périer, C. R. 108, 1202), and much apparent contradiction exists on the subject; but the bulk of this disappears when the processes by which the figures were obtained are inquired into. The general agreement is with the numbers of Balling, confirmed, within the limits of error, by Scheibler a. Mategczek (Z. V. 15, 586; 24, 827; 27, 32) and others. These are:—

Per cent. saccharon	Sp. gr. sol.
in sol.	17:60
5	1·01970
10	1.04014
20	1.08329
40	1.17943

The relation is sometimes more convenient when expressed as weights in measure. If a vessel be made to hold 100 g. H₂O at 15.5°, and such is the 100 c.c. vessel most generally in use, then a solution containing

20 g. saccharon in this 100 c.c. = sp. gr. 1.07686 10 1.03857 •• .. 5 1.01931 ,, •• 1.00386 Hence, if the sp.gr. of a pure cane sugar is known the amount of sugar in the 100 c.c. can be arrived at broadly by dividing the S.G. -1.000bv ·00385. This number multiplied by 1000 has been called the D of the sugar. D = 3.85 for saccharon. The use of the number gives too low an indication for the higher specific gravities and too high a one for the lower ones, being almost accurate for solutions containing between 10 and 20 g. sugar per 100 c.c. It is a useful, practical factor when its meaning and value are understood, being at most 3 per 1000 incorrect.

Concentrated sugar solutions possess a higher boiling-point than water, an 80 p.c. solution boils at 112°, a 90.8 p.c. solution at 130° (Gerlach, D. P. J. 172, 31 and 286).

Solutions of pure cane sugar crystallise quickly, but if foreign matters are present the crystallisation is very much slower, and the forms of the crystals vary with the character of the impurity; some impurities entirely prevent crystallisation. These facts play a most important part in the refinery (see art. in Dictronary of Applied Chemistry and v. Lippmann's Zuckerarten, p. 115). Solutions of cane sugar are highly diactinic (Hartley, C. J. 1887, 59). Cane sugar is soluble in methyl and ethyl alcohol, acetone, and glycerin in proportion to the amount of water they contain, being almost insoluble in them when they are anhydrous (Scheibler, Z. V. 22, 246; B. 5, 343). Solutions of cane sugar and the fused sugar are optically active, rotating the plane of polarisation to the right; crystallised sugar is not optically active. The oldest value given for specific rotatory power is [a]₁ = +78.8° = [a]₀ = +66.6° (24:21.67:78.8°:66.6°).

This is only an approximate average number, much of the same value as the D described

above. It is the apparent specific rotatory power, and may be called the working value. Tollens (B. 17, 1757), Schmitz (B. 10, 1419), Girard a. de Luynes (C. R. 80, 1355), and Calderon (C. R. 83, 393), from numerous observations worked out an absolute value. Tollens gives $[\alpha]_{\rm p} = 66.386 + 0.015035 {\rm P} - 0.0003986 {\rm P}^2$. P is the p.c. of sugar; Schmitz's numbers are $[\alpha]_D = 64\cdot156 + 0\cdot051596q - 0\cdot00028052q^2$, where q = p.c. of water. The optical activity diminishes with the concentration of the solution, so that for a 100 p.c. solution (i.e. for the dry sugar, if the curve follows the same course as the observations) the specific rotatory power is $[a]_0 = 64^\circ$ approximately, while very weak solutions, as 1 p.c. for example, it is $[a]_p = 67^\circ$ (Pibram, B. 20, 1849; Nasini a. Villavecchia, Gaz. 22, 1, 97). The temperature of observation has but a very slight influence on the optical activity (Dubrunfaut, A. Ch. [3] 18, 99; Andrews, M. S. [4] 3, 1366). The specific rotatory powers of solutions of the sugar in mixtures of water and ethyl alcohol, methyl alcohol, and acetone respectively are slightly greater than that of aqueous solutions; if the latter be taken at $[a]_D = 66.67^\circ$ they are respectively $[a]_D = 66.83^\circ$, 68.63° , and 67.40° (Tollens, B. C. 1881,570). The optical activity of fused sugar is less than that of its solutions, and diminishes according to the length of time it has been kept fused. This is, no doubt, due to the presence of decomposition products. The specific rotatory power of aqueous solutions is altered by the presence of most foreign substances; alkalis and alkaline earths diminish it (Thomsen, B. 14, 1649; v. Lippmann, Zuckerarten, p. 157; Farnsteiner, B. 23, 3570). Lead acetate does not appear to have any influence, while ammonia increases the rotation (Ost, N. Zcitsch. f. Rübenz .-Ind. 9, 42). The dispersion of cane-sugar solutions is almost the same as that of quartz, so that the rotation of the plane of polarisation caused by a sugar solution may be almost completely neutralised by a plate of left-handed quartz of the correct thickness. Grimbert (J. Ph. [5] 16, 295) gives $[a]_0 = 66.45^\circ$ and $[a]_0 = 52.85^\circ$, so that the dispersive power for these two wave-lengths is 1.257. The refractive index for sugar solutions has been determined for seven lines of the spectrum (Obermeyer, Landolt-Börnstein, Physikalisch-chem. Tabellen, Berlin, 1883, p. 213; Kanonnikoff, B. 16, 3047). Gladstone (C. J. 1891, 589) finds the molecular refraction of cane-sugar solutions to be 118.7 for the A line, and the molecular dispersion be-

tween A and H lines 4.73.

Action of heat. Dry cane sugar melts at 160°, and solidifies ou cooling, if care be taken and the temperature does not exceed 160°, to a colourless, glassy mass; but if the temperature be maintained the fused mass becomes slightly coloured, and on cooling yields the substance known as barley-sugar, this ofter a time becomes crystalline; but even with the greatest care it seems impossible to fuse the sugar without producing some decomposition. With the appearance of the colour dextrose and lævulosan are probably the chief products; but although much work has been done on the subject, the exact nature of the alteration is not settled. A little furfural is formed at times (Gélis, A. Ch. [3] 57, 234; C. R. 51, 331; Schiff, B. 20, 540). When the tempe

¹ Z. V.=Zelischrift des Vereins für die Rübensucker in-Entirie des deutschen Reichet.

rature is raised to 200° distinct decomposition sets in, caramel is formed, gases are evolved, and finally a residue of charcoal remains. Among the gases are carbon dioxide, carbon monoxide, marsh gas, ethylene, acetylene; among the volatile products are water, acetone, formic, acetic, and propionic acids, aldehyde, furfural, acrolein, benzoic aldehyde, and a bitter substance assamur (Völckel, A. 85, 59; 86, 63; 87, 303; Fremy, A. 15, 278; Schiff, B. 20, 540; A. 238, 380; Reichenbach, A. 49, 3). Caramel has the same composition as cane sugar, less one or more molecules of water. It is soluble in water and partly soluble in alcohol, and probably consists of a mixture of several bodies. Baryta and basic lead acetate give precipitates with it. It combines with aniline, reduces some metallic salts, and yields an acid with chlorine. It is largely used as a colouring matter in cookery, brewing, &c. (Gélis, A. Ch. [3] 52, 386; 65, 190 a. 496; Graham, A. Ch. 65, 190; Péligot, A. Ch. [2] 67, 172; Völckel, A. 75, 59; 85, 74; Pohl, J. pr. 82, 148; Schiff, B. 4, 908; Wachtel, Org. d. Centr.-Ver. 17, 930).

It seems proved that when dry saccharon is heated at 100°, even for a long time, no change takes place, and, as has been said, the sugar can be heated to the melting-point, 160°, without producing any marked decomposition, but it would appear that rapid heating to this temperature can produce a mixture of dextrose and lævulosan, without any change in weight. If, however, a mixture of 100 pts. of the sugar and about 5 pts. water is heated at 150° for some time. a mixture is produced which contains little or no unaltered saccharon, but which consists, in part at least, of a sugar said to be optically inactive, and to be a compound of bi-rotating dextrose and lævulose. Other bodies must also be present, probably dextrose and lævulose. The compound sugar is, no doubt, present, but inasmuch as it has never been isolated it cannot be said with certainty that it is inactive (Morin, C. R. 86, 1033; Berzelius a. Mitscherlich, J. Ph. 3, 4, 216). The so-called inactive sugar is easily converted by boiling with water into dextrose and lævulose. Neutral aqueous solutions of saccharon are slowly inverted on boiling. They are, however, stable in the cold, if sterilised, and can be concentrated under diminished pressure at 50°-60° without undergoing much change (Kreuster, Z. V. 25, 521; Béchamp, A. Ch. [3] 54, 28; Morin, C. R. 86, 1,083; Horsin-Déon, Bl. [2] 32,121; Gunning, Z. V. 27, 895). By heating to 150°-200° in a sealed tube, humus substances, formic acid, pyrocatechin, and other bodies are formed (Löw, Z. 1867, 510; Hoppe-Seyler, B. 4, 15).

Action of acids. All dilute acids, even carbonic acid, hydrolyse (invert) cane sugar, causing the assimilation of one molecule of water and the production of equal quantities of dextrose and lævulose,

Saccharon Dextrose Levulose $O_{18}H_{20}O_{11}+H_{2}O=C_{8}H_{12}O_{4}+C_{6}H_{12}O_{5}$. This mixture is called invert sugar. The experiments made on this phenomenon may be classified under two headings: (a) the action of different acids acting under the same conditions on the sugar solutions; (b) the action of the

same acids under varying conditions.

regard to those coming under the first heading, Ostwald's experiments are the most complete (J. pr. [2] 29 385; 30, 98 a. 225; 81, 807; Koral, J. pr. [2] 34, 109). He examined the action of thirty-two acids, and finds that there is a close relation between the constants of inversion and the affinities of the acids. See also Fleury (D. P. J. 219, 436; J. Ph. [4] 22, 423). With regard to reactions coming under the second heading, it is found that inversion proceeds more rapidly in hot solutions than in cold ones (several formulæ have been given to express this relation, v. Arrhenius, Zeit. phys. Ch. 4, 226; Urech, B. 20, 1836); that increase in the percentage of acid increases the rapidity of inversion; that, the percentage of acid to water being constant, increase of volume decreases the time; and that the percentage of acid to sugar being constant, increase of volume (dilution) increases the time (Löwenthal a. Lenssen, J. pr. 85, 321 a. 401; Urech, B. 13, 1696; 15, 2130; B. C. 1881, 570; 1883. 501). The presence of neutral salts sometimes increases and sometimes diminishes the rapidity of inversion; for a detailed account see Spohr (J. pr. [2] 32, 32 and 33, 265). If the heating be long continued, or if too strong acids be used, most of the lævulose and part of the dextrose is destroyed, and humus substances, acetopropionic and formic acids are produced Mulder, J. pr. 21, 219; Malaguti, A. 17, 52; Stein, A. 30, 82; Conrad, B. 11, 2178; Tollens, B. 14, 1951; Sestini, L. V. 26, 235; 27, 163; Conrad a. Guthzeit, B. 18, 439; 19, 2569 a. 2814; Tollens a. Grote, A. 175, 181, 206, 237 a. 233. The inversion of cane sugar cannot be carried out by heating with acids without destroying some lævulose (q. v.), unless the temperature and quantity of acid be kept within welldefined limits (Jungfleisch a. Grimbert, C. R. 108, 144; Wohl, B. 23, 2084). Nicol (Fr. 14, 180) and Clerget (A. Ch. [3] 26, 175) give instructions for the preparation of pure invert sugar. According to the latter, 5 c.c. of strong hydrochloric acid is added to 50 c.c. sugar solution, containing 8.175 g. saccharon, and heated for ten minutes at 68°. Under these conditions the sugar is completely inverted, and the products are unacted upon. They are identical in optical activity and cupric reducing power with the sugar obtained by the action of invertase (see Action of ferments) under the most favourable conditions. There is no doubt that invert sugar is a mixture of lævulose and dextrose in equal quantities (Jungfleisch a. Grimbert, C. R. 108, 144; 107, 390), as its properties agree in every particular with that of a mixture of these two sugars in molecular proportions. Concentrated sulphuric acid dissolves cane sugar at the freezing temperature, without the production of colour, but slight heating causes it to swell up to a black, frothy mass; a blue fluorescent body is formed (Simmler, C. C. 1862, 378). Other acids act in a similar way (Gmelin-Kraut, Hand

buch d. Ch.; van Kerckhoff, J. pr. 69, 48).

Action of alkalis. Dilute alkalis do not act on cane sugar in the cold, and but slowly on neating (Michaelis, J. pr. 56, 430). By heating with potassium hydroxide and but little water, decomposition takes place, carbon dioxide, acetone, and formic, acetic, propionic, and oxalic acids are formed (Gottlieb, A. 52, 122). Potash

or baryta under certain conditions yield a large quantity of lactic acid (Schützenberger, Bl. [2] 25, 289). Milk of lime and strontia also decompose cane sugar by prolonged heating (Fremy, A. 15, 278; Benedict, A. 162, 303; Niedschlag, Deutsche Zuckerind. 1887. 159; Pinner, B. 16.

Oxidation. Cane sugar is easily oxidised by almost all the common oxidising agents. Free oxygen does not act on it, but in the presence of platinum black it does; ozone also oxidises it (Gorup-Besanez, A. 110, 103). Chlorine or bromine yields gluconic acid, glucos, and other substances (Reichardt, B. C. 1880, 559; Grieshammer, A. Ph. [3] 15, 193); the same reaction takes place in the presence of lead or silver oxide (Hlasiwetz a. Habermann, A. 155, 128; Herzfeld, A. 220, 353). Iodine and potassium carbonate yield a little iodoform (Millon, C. R. 21,828). The more powerful oxidising reagents... such as strong chromic acid, chlorate of potash. strong sulphuric acid, &c .- act so violently as to cause explosions. Strong nitric acid acts very energetically; dilute nitric acid yields sacchario and oxalic acids; anhydrous nitric acid, or a mixture of strong nitric and sulphuric acids, yields mixtre of strong introducts supported acids, yields a nitrate (Sobero, C. R. 24, 247; Schönbein, P. 70, 104; Carey-Lea, Bl. [2] 10, 415; Tollens, B. 15, 1828; Salkowski, B. 15, 1738; Heintz, A. 51, 185; P. 61, 315; Reinsch, Jahrb. f. Pharm. 18, 337; Hornemann, J. pr. 89, 304; Tollens, Chem. Zeit. 11, 1178). Fehling's solution is not reduced by cane-sugar solution, neither are alkaline solutions of other oxides, except ammoniacal silver solutions, which are reduced slowly in the cold and quicker on warming; but many neutral or acid metallic solutions are reduced (Tollens, Z. V. 82, 712; B. 15, 1828; Salkowski, B. 15, 1738). Dilute chromic acid oxidises cane sugar to oxalic, formic, and carbonic acids; potassium permanganate yields carbonic acid and water; by careful oxidation in the cold, oxalic and formic acids are also produced (Heyer, Ar. Ph. [3] 20, 336 a. 430; Brunner, B. 12, 549). Maumené (Bl. [2] 22, 2; 30, 99) says that three acids, di-, tri-, and hexa-pinic acids C2H4O4, C₂H₂O₃, and C₆H₁₂O₃, are formed under certain

conditions. Action of ferments. Cane sugar is not directly fermentable by organised ferments, with the exception of Monila candida; it requires first to be hydrolysed (inverted), and for this purpose every organism which has the power of assimilating cane sugar produces an organised ferment or enzyme called *invertase*, which first inverts it (Bernard, Lecons de Physiologie Exper., Paris, 1856; Hansen, Meddelelser, 1888, 2, 143; Brown, O. J. 1886. 173). The action of invertase was first studied by Kjeldahl (Meddelelser, 1881, 3, 186); O'Sullivan and Tompson (C. J. 1890, 834) have exhaustively investigated the subject. They find the change follows the same time curve as a catalytic reaction; the time necessary to perform a given percentage of hydrolysis varies directly with the amount of invertage; the most favourable concentration of the sugar solution is 20-25 p.c., and the most favourable temperature 55°. Hydrolysis proceeds slowly at the freezing-point; it ceases at about 65°; alkalis immediately stop the reaction, whereas very minute quantities of acid

aid it. Invertase is uninjured by the reaction, and is capable of inverting about twenty-two times its weight of cane sugar per minute for an unlimited period. The dextrose formed is in the bi-rotatory state; on standing, the invert'sugar has the same optical activity as that obtained by the careful action of dilute acids. See also Barth (B. 11, 474), Mayer (B. C. 1881, 784; 1882, 850), Müller (Ann. Agronom. 12, 481), Tamman (Zeit. phys. Ch. 3, 25). Invertase acts at a temperature higher than is sufficient to kill the yeast whence it is derived. For production of alcohol. acids, &c., under the influence of organised ferments, see FERMENTATION.

Compounds with acids. Nitrosaccharon $C_{12}H_{18}(NO_2)_4O_{11}$ is prepared by treating the powdered sugar with a mixture of strong H_4SO_4 and fuming HNO, in the cold (Schönbein, P. 70, 167; Sobero, C. R. 24, 247). It is a white doughy mass, insoluble in water, soluble in alcohol and ether. Boiling water decomposes it;
Li.p. 20°. It is explosive.

With arsenious acid a compound

C12H22O11.As2O3 is said to be produced. The composition is improbable.

By the action of acetic anhydride and glacial acetic acid, or acetic anhydride and sodium acetate, a series of acetates have been obtained. In these the group CoH,O takes the place of H. We have the monoacetate $C_{12}H_{21}(C_2H_2O)O_{11}$ (Schützenberger a. Naudin, Bl. 12, 206); the (Herzfeld, N. Z. 3, 155); the hexacetate (Schützenberger, Bl. 12, 204; C. R. 61, 485); and the octacetate (Herzfeld, B. 13, 267; Démole, C. R. 89, 481), all more or less resinous substances. diminishing in solubility in water in proportion to the number of acetyl groups they contain, and increasing in solubility in alcohol and ether with the same change in composition. The octacetate is said to crystallise in needles, m.p. 67°. They are all decomposed by the action of acids and alkalis into acetic acid and the products of the inversion of saccharon. It is probable that by careful treatment with alkalis in equivalent quantities (sufficient to neutralise the acetic acid formed) saccharon is again produced. Benzoyl chloride yields with saccharon (Baumann, B. 19, 3220; Skraup, M. 10, 389).

Compounds with bases. By mixing sodium

ethylate with a solution of cane sugar and precipitating with alcohol, a compound C₁₂H₂NaO₁₁ is obtained (Pleisser a. Tollens, A. 211, 285). A similar potassium compound has been prepared (Soubeyran, A. 43, 223; Brendeche, An. Ph. [2] 29, 73). Cane sugar combines with many bases, forming saccharates which are decomposed into the sugar and carbonate by carbon dioxide, and are but slightly soluble in water. The most important of these are barium saccharate $C_{12}H_{22}O_{11}$ BaO, strontium saccharate $C_{12}H_{22}O_{11}$ SrO, and $C_{12}H_{22}O_{11}$ 2SrO, the former produced by mixing solutions of its constituents; it crystallises with $\delta H_{2}O_{1}$, the latter obtained by bringing together its constituents obtained by bringing solution. Calcium saccharates: C₁₂H₂₂O₁₁.8CaO 3aq is but slightly soluble in water; C₁₂H₂₂O₁₁.2CaO 2aq and C₁₂H₂₂O₁₁.2CaO are soluble in water and decomposed partly by Calcium saccharates:. boiling into the tri-saccharate and free sugar,

 $C_{12}H_{22}O_{11}.CaO + 2H_2O_1$ C₁₂H₂₂O₁₁.2CaO, (C₁₂H₂₂O₁₁)₂8CaO have also been described. Lead acetate alone does not precipitate cane sugar; lead acetate and ammonia yield $C_{12}H_{18}Pb_2O_{11}$ and $C_{12}H_{18}Pb_2O_{11}$; iron and copper yield saccharates; it is doubtful if magnesia forms one (Soubeyran, A. 43, 223; Stromeyer, Ar. Ph. [3] 25, 229; Brendeche, Ar. Ph. [2] 29, 73; Péligot, J. pr. 13, 379; 15, 76; A. [3] 54, 377; Landolt a. Degener, Z. V. 32, 325; Scheibler, B. 15, 2945; 16, 985; v. Lippmann, Organ d. Centr. Ver. 18, 37; B. 16, 2764; Benedict, B. 6,413; Harperath, Chem. Zeit. 1886. 323; Boivin a. Loiseau, C. R. 58, 60; also old editions of Watts' Dict.). Ammonia gas at 150° forms brown amorphous bodies; solutions of ammonia yield similar bodies (Thénard, C. R. 52, 444; Payen a. Schützenberger, Jahresber. f. Zuckerfabr. 1861-62, p. 191, 192; Laborde, J. 1874, 883).

Compounds with metallic salts. Several compounds of saccharon with sodium chloride, bromide, and iodide have been prepared (Péligot, A. 30, 71; Maumené, Bl. 15, 1; Gill, C. J. 1871, 269). Such compounds are C₁₈H₂₂O₁₁.NaCl.2H₂O; 2C₁₂H₂₂O₁₁.3NaCl.4H₂O; C₁₂H₂₂O₁₁.NaBr.1½H₂O;and2C₁₂H₂₂O₁₁.3NaL.3H₂O; the latter is a very stable and definite compound, and is, like the others, easily prepared by boiling a mixture of the sodium salt and saccharon in equivalent quantities, and allowing the solution to stand in a quiet place over sulphuric acid. These bodies form distinct and definite crystals. No definite compounds of the halogen salts of potassium and ammonium with saccharon have been described, but there can be little doubt. from the work of Gill, that such are obtainable. Lithium salts seem to give lithium compounds. Compounds of saccharon with sodium-acetate. nitrate, iodate, and phosphate are not obtainable (Gill, l.c.). A double salt of copper sulphate and saccharon, C12H22O11.CuSO4.2aq crystallises from a saturated solution of the constituents (Barreswil, J. Ph. [3] 7, 29). The sodium mercury chloride compound crystals on the slow evaporation of a solution of its constituents in weak alcohol (Boullay, Bl. 12, 292). A borax compound 3C₁H₂O₁, Na₂B₄O₂, 4H₂O has also been described (Stürenberg, Ar. Ph. 18, 279). Many other compounds have been described, but they present no material interest.

Saccharon, like many other organic substances, prevents the precipitation of many metals from their solutions by ammonium, sodium, and potassium hydroxide; in some cases the prevention is complete, in others only a portion of the metal is retained in solution (Lussaigne, C. R. 14, 691; Groth, J. pr. [1] 92, 175; Pellet J. Fabr. 18, 22).

cows, 6 p.c. of asses' milk, and a slightly greater proportion of mare's milk (Fleischmann, Das Molkereiwesen, Braunschweig, 1875; Kühne, Lehrb. d. physiol. Ch. p. 573).

Preparation.—Skim milk, or, better, milk from which the fat has been separated by mechanical means, is coagulated with rennet and the whey digested for some time with calcium carbonate (chalk) and aluminium hydroxide. The insoluble matter is then filtered out and the filtrate concentrated in a vacuum to a syrup; this, on standing, yields crystals of lactose. During concentration some matter becomes insoluble; this should be filtered out before final concentration. The crystals are purified by repeated re-crystallisation from solutions concentrated at the temperature of boiling water; on cooling C1.H2O11.H2O crystallises. This is lactose a. If the saturated solution is evaporated rapidly on the water bath with continual stirring, small crystals of C12H2.O11 are obtained; lactose y. These are not hygroscopic. If the a modification is dried at 130° a hygroscopic mass is left, which is known as the β modification. There are said to be other modifications, but in solution after boiling they all have the same optical activity and are identical (Enling a. Rüf, B. C. 1882, 346; Centbl.

f. Ag. Ch. 1885, 130; J. Kunz, Ph. [3] 15, 443).
Properties.—Ordinary lactose forms large, rhombic, hemihedral crystals, having a sp.gr. 1.53-1.54 (Schröder, B. 12, 562) and containing 1 mol. H.O. which is lost by drying at 130°. It is soluble in six parts of cold water and in two and a-half or less of boiling water, from which on cooling it slowly crystallises. Its solutions rotate the plane of polarisation to the right, and its specific rotatory power for the D line is [a]_b = $52 \cdot 53^{\circ} + (20 - t) \times 0.055$ (Schmöger, B. 13, 1927; Hesse, A. 176, 98; Erdmann, J. 1855, 661; Denigès a. Bonnans, J. Ph. [5] 17, 363 a. 411). The variation with the concentration is very little, and, as is obvious from the above formula, the effect of temperature is slight. These numbers for the $[a]_D$ are calculated for the crystals $C_{12}H_{22}O_{11}$. H₂O. For the dry sugar $C_{12}H_{22}O_{11}$ I have found $[a]_D = 55.5^\circ$ with a Jellet-Cornu instrument (Schmidt a. Hans, Ch.), sodium flame, and absolutely the same number $[a]_1 = 61.6^{\circ}$ with a Soleil-Scheibler, taking 100 divs. = 38.4°.

 $(24:21.67::61.6^{\circ}:55.5^{\circ})$. $55.5^{\circ}-5.25$ p.e. = 52.59: my observations were made at 15.5°, Schmöger's at 20°. Freshly-prepared solutions of crystallised lactose exhibit the phenomenon of bi-rotation, the angle immediately after solution being in the proportion of 8:5 to the constant value (Urech, B. 16, 2270; Dubrunfaut, C. R. 42, 228; Schmöger, l.c.; Parcus a. Tollens, A. 257, 160). The rotatory power does not vary with the concentration. The dispersive power-that is, the ratio between the specific rotatory powers for the C and D lines—is 1:1.259 ([α]₀ = 41.58) (Grimbert, J. Ph. [5] 16, 295 a. 345). The modification γ when freshly dissolved in water exhibits the phenomenon of semi-rotation—that is, the specific rotatory power is only about § of the normal, to which it attains on standing a few hours (E. O. Erdmann, Fortschritte der Physik, 1855, 13; B. 13, 2180; Schmöger, B. 13, 1915). The modification β on solution has immediately the normal optical activity; the presence of alkali lowers the

activity (Schmöger, L.c.; Urech, B. 17, 1543). Schmöger give the specific gravity of solutions, containing given percentages of the crystals from which by calculation we get D=3°956 for a solution containing 2.5 g. dry sugar in 100 c.c. at 20°, 3°921 for a 10 g. solution and 3°913 for a 15 g. one. My observations are, temporature 15°5°:—

1 gram in 100 c.c. sp.gr. $\frac{155}{155}$ 1·0040; D = 4·00 5 grams, 1-0199; D = 3·98 10 , 1-0397; D = 3·97 20 , 1-0785; D = 3·93

D=3·99 for solution below 10 g. per 100 c.c. at 15·5°. The K=79·2 for dry sugar, i.e. 0·5723 anhydrous lactose reduce 1 g. CuO from Fehling's solution (Jones, Analyst, 1889, 81). According to Soxhlet 0·5 g. sugar=74 c.c. Fehling's solution, hence K=74; in this case 1 g. CuO=0·127 lactose: by weighing the precipitated CuO as Cu by Allihn's method, 1 g. sugar=1·736 CuO, or 1 g. CuO=0·5760 g. sugar, K=78·8, agreeing with the number given by Jones. According to Roderwald a. Tollens (B. 11, 2076) the working number 1 g. CuO=0·5795 g. anlydrous sugar. I am inclined, when the conditions hereafter to be described are followed, to place the K at 78·9, i.e. 1 g. CuO=0·5768 g. sugar. In this case 7·5 mols. CuO are reduced by 1 mol. sugar.

Action of heat. Hydrous crystallised lactose (a) remains constant at 100°; above this water is slowly given off, and at 130° the dehydration is complete without decomposition if the water is climinated slowly. Anhydrous lactose commences to colour at 170°-180°, loses water, and forms the so-called lactocaramel C_oH₁₀O_s, which is easily soluble in water but insoluble in alcohol, and yields compounds with lead and copper oxide. Lactose melts at 203·5° to a brown liquid, and by further heating it is decomposed with separation of carbon (Lieben, J. pr. 68, 409). Heated in a scaled tube with water to 90°-100° it is coloured, and more so at 180°-200°, when a glucose is produced which may be precipitated by alcohol, and, by further heating, carbonic acid, a little pyrocatechin, and other bodies are formed (Vohl, A. 105, 334; Hoppe-Seyler, B. 4, 16; Munk, H. 1, 357).

Action of acids. By heating with dilute acids lactose is hydrolysed (inverted), yielding galactose and dextrose

$$C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6$$

Lactose Dextrose Galactose

one molecule of water being taken up. The reaction takes some hours to complete; during the hydrolysis the reducing power and optical activity increase (Pasteur, G. R. 42, 223; Fudakowski, B.8, 559; 9, 42; 278 and 1602; 11, 1069; Bourquelot, N. Ztschr. f. Rubenz-ind. 16, 71; Kent a. Tollens, A. 227, 221; Rindell, N. Ztschr. f. Rubenz-ind. 4, 163). The chief products of the reaction are as stated, but the conditions have not yet been described by which the optical activity and K of the resulting substances will exactly correspond with those of a mixture of equal parts of galactose and dextrose. Other bodies are undoubtedly produced. By the continued action of acids for several days, aceto-propionic and formic acids are produced (Tollens a. Roderwald, A. 206, 231; Conrad a. Guthzeit,

B. 19, 2575). Concentrated sulphuric acid does not blacken lactose in the cold.

Compounds with acids. A mixture of sulphuric and nitric acids give lactose pentanitrate $C_{12}H_{17}(NO_2)_5O_{11}$, insoluble in water but soluble in alcohol and ether, m.p. 139.2° and exploding when struck by a hammer on an anvil; lactose tri-nitrate C₁₂H₁₈(NO₂)₃O₁₁, very slightly soluble in water, but easily in alcohol and ether, m.p. 37° ; and lactose tetranitrate $C_{12}H_{18}(NO_2),O_{11}$, m.p. 80° – 81° (Gé, J. R. 1882, 253; B. 15, 2238). With chlorosulphonic acid lactose yields dextrosetetra-sulphonic acid chloride (Claesson, J. pr. [2] 20, 1 and 18). Organic acids act very slowly on lactose, but by prolonged action they yield ethers of lactose or of dextrose and galactose (Berthelot, Chim. org. 2, 279, 295). A series of acetates, beginning with the mono-body and ending with the octo-one, have been described. C12H11(C2H3O)8O11 is obtained by boiling lactose with an excess of acetic anhydride or by heating a mixture in the proper proportions of the sugar, acetic anhydride, and fused sodium acetate at 100° (Herzfeld, B. 13, 265). This body is insoluble in water and in ether, soluble in benzene, acetic acid, and in alcohol. It crystallises from a mixture of alcohol and acetic ether. $[\alpha]_D = +31^\circ$ in alcoholic solution. The mono- and di- acetate are obtained by incompletely decomposing the octo-acetate by alkalis (Démole, C. R. 89, 481). Tetracetate is formed at the same time as the octo- acetate, when lactose is boiled with acetic anhydride (Schützenberger a. Naudin, Bl. 12, 208). It is easily soluble in water, $[a]_p = +50^\circ$. Hexacetate C12H16(C2H2O)O11 crystallises from a mixture of alcohol and acetic ether in white needles, m p. 86° (Herzfeld, N. Z. R. 3, 156). It is doubtful whether or not lactose is reproduced when these bodies are saponified by treatment with alkalis. There seems to be no reason why it should not be so, if the alkali is carefully employed.

Action of alkalis. Hot alkalis colour solutions of lactose yellow to brown, and form lactic acid, pyrocatechin, and other products (Hoppe-Seyler, B. 4, 347; Nencki a. Sieber, J. pr. [2] 34, 503; Urech, B. 17, 1543). Fused with KHO it yields carbonic, oxalic, and a little succinic acids (Hlasiwetz a. Barth, A. 138, 76).

Compounds with alkalis. Lactoseates are formed by the action of potash or soda on lactose in alcoholic solutions, or by adding alcohol to the mixed aqueous solutions. They are amorphous, easily decomposed precipitates having a composition expressed by the formulæ C₁₂H₂₁NaO₁₁ and C₁₂H₂₁KO₁₁ (Fremy, A. 15, 278; Hönig a. Rosenfeld, B. 12, 45). Calcium, barium, and lead lactoseates are obtained by dissolving the base in lactose solution and precipitating with alcohol. The long-continued action of lime produces isosaccharin and metasaccharin (Cuisinier, M. S. [3] 12, 520; Kiliani, B. 16, 2625). By heating with ammonia, brown, amorphous, nitrogenous products are obtained (Thénard, C. R. 52, 444). Aniline yields two crystalline compounds, C₁₀H₁₀NO₂₁ and C₁₀H₁₀NO₂₀, which reduce Fehling's solution (Sachsse, B. 4, 835; L. V. 16, 441).

Oxidation.—Oxygen and ozone have no action on lactose in the cold; hot solutions are oxidised by oxygen in the presence of platinum black (Gorup-Besanez, A. 110, 86 a. 103; Reiset

a. Millon, A. Ch. [3] 8. 295). Alkaline permanganate solutions oxidise lactose easily (Laubenheimer, A. 164, 288). Chromic acid yields aldebyde (Guckelberger, A. 64, 98). Nitric acid hyde (Guckelberger, A. 64, 98). Nitric acid first inverts lactose and then yields mucic and saccharic acids; from 86 to 40 p.c. of mucic acid is produced; by long-continued heating tartaric and oxalic acids, &c., are obtained (Liebig, A. 113, 1; Dubrunfaut, C. R. 42, 228; Kent a. Tollens, A. 227, 227). Alkaline solutions of copper oxide are reduced by lactose, and from amongst the products of the reaction Bödecker a. Struckmann (A. 100, 264) isolated gallactinic acid $C_{14}H_{10}O_{9}$; pectolactinic acid $C_{16}H_{16}O_{12}$, lactic and glycollic acids are also produced (Habermann a. Hönig, B. 17, 351). Silver oxide oxidises lactose solutions with production of oxalic, glycollic, and lactonic (galactonic) acids (Kiliani, B. 13, 2307). Chlorine or bromine in the presence of silver oxide yield lactonic (galactonic) acid C₂H_{1,2}O₂ (Barth a. Hlasiwetz, A. 119, 281; 122, 96). By very careful oxidation with bromine water Fischer a. Meyer (B. 22, 361) have obtained lactobionic acid C12H22O12; it is a colourless, strongly acid syrup, easily soluble in water, but only sparingly in alcohol. It does not reduce Fehling's solution; it decomposes metallic carbonates, forming salts. The calcium $(C_{12}H_{21}O_{12})_2Ca$, barium $(C_{12}H_{21}O_{12})_2Ba$, lead (C12H21O12)Pb, and other salts may be prepared in this way; they are insoluble in alcohol, but soluble in water. When heated with dilute mineral acids, lactobionic acid is decomposed into galactose and gluconic acid. With iodine and sodium bicarbonate lactose yields a little iodoform (Millon, C. R. 21, 828).

Fermentation.—There is no known enzyme capable of inverting lactose; it does not ferment with yeast (Berthelot, A. Ch. [3] 50, 332 a. 362; Fitz, B. 11, 42). It easily undergoes lactic acid fermentation, especially in milk (Fitz, l.c.; Richet, C. R. 86, 550; Schmidt-Mülheim, B. 15, 2631). It undergoes alcoholic fermentation in kumys or kefir fermentation (Struve, B. 17, 314; Vieth, A. 12, 2), and also under the agency of certain bacteria (Rotondi a. Zechini, see v. Lippmann, Deutsche Zuckerind. 1887, 1091).

Phenylhydrazine yields lactose phenylhydraside C₁₁H₂₂O₁₆N₂, soluble in water and alcohol, insoluble in ether and levorotatory, and lactose osazone C₂H₂₂N₄O₃, crystallising in yellow needles; soluble to some extent in hot water, and m.p. 200° (Fischer, B. 17, 583; 20, 830; 20, 2566). By the action of hydrochloric acid it yields lactose osone (Fischer, B. 21, 2631).

Maltose. Maltobiose, Anylon, C.,H.,O.,;
C.,H.,O.,,H.,O. De Saussure (Bibl. Britannique,
56, 1814, 333; P. 1819, 29, 58) may have obtained this sugar when studying the products of
the spontaneous decomposition of starch-paste
when exposed to the air at 20°-25°. GuérinVarry (A. Ch. 60, 32; 61, 66) described accurately
how the body could be prepared in the crystallised state and some of its properties, but failed
to recognise it as a distinct substance; Jacquelain (A. Ch. 68, 167) added nothing to Varry's
work; Dubrunfaut (A. Ch. [3] 21, 78) prepared
the body according to Varry's method, observed
that it was less soluble in alcohol than dextrose,
and had an optical activity three times as great,
46, [a] = 58 × 3 = 174, a figure so high as to lead

one to believe that he had not a pure body in his hands. He recognised it as a distinct body, and called it maltose; he, however, looked upon it as a glucose, triglucose; O'Sullivan (C. J. 1872, 576; 1876, 478) showed that it was not an 'ose' but an 'on' sugar, and from this and a fuller description of its characters gave it a place among chemical entities.

Occurrence.—It is present in some commercial glucoses and in beer (Valentin, J. S. A. 24, 404); probably in bread; in ame, a rice-extract prepared in Japan (Yoshida, C. N. 43, 29), and in germinated cereals to the extent of 1 to 2 p.o. (O'Sullivan, C. J. 49, 58). After feeding with amylaceous substances it is found in the intestinal canal, but the blood of the mesenteries contains only dextrose. If injected into a vein it is found in the urine; if injected subcutaneously, it is partially converted into dextrose (Phillips, B. C. 1882, 127). Some of the reducing sugars of blood may be maltose.

Formation.—Diastase converts starch and the dextrins into maltose (O'Sullivan, L.c.). The ferment of saliva, ptyalin, of the pancras, and of the liver, act in the same way (Nasse, J. Th. 1877, 62; Musculus a. v. Mering, Z. 2, 403). The same ferments act on glycogen, maltose being amongst the products; dextrose is present when saliva is employed (Kütz, Pf. 24, 8). All mineral acids and many organic acids act on starch and glycogen; maltose is amongst the products.

Preparation .- 100 g. purified starch are mixed as completely as possible with 300 c.c. water at 40°, and then poured with continuous stirring into 2 litres of boiling water. The paste is cooled to 60° and the extract from 20 g. pale malt added to it; the mixture is kept at 60°-63° for four or five hours, and the solution may be allowed to cool and stand for a few days. At the end of that time it is evaporated, best in a vacuum, to 200 c.c., and then boiled with 2 litres alcohol, sp.gr. 820. On cooling and standing, the clear liquid is decanted off the undissolved syrup and put aside in a corked flask; at the end of six days the sides of the flask will be found to be covered with a crystalline crust of maltose. Or the undissolved syrup may be treated with strong alcohol as long as any matter is taken up, the whole of the clear alcoholic solutions are mixed, the alcohol distilled off and the residue concentrated to a syrup; this on standing in a cool place becomes filled with crystals of maltose, especially if a few crystals from a previous preparation be stirred in. These may be washed with dry methyl alcohol; if this is used hot, a portion of the crystals dissolves and the solution soon yields much sugar. The crystallisation is hastened by adding half a volume of ethyl alcohol (.810 sp.gr.) or a little ether with some crystals of a previous prepara-tion (O'Sullivan, *l.c.*; Schulze, *B.* 7, 1047; Soxhlet, *J. pr.* [2] 21, 277; Herzfeld, *A. Ch.* 220, 209; Cuisinier, J. 1884, 1803). The body may be purified by recrystallisation from methyl alcohol or water.

Properties.—Maltose crystallises out of water in plates which contain $C_{12}H_{22}O_{11}.H_{2}O$; out of alcohol (sp. gr. 810) it crystallises in crusts and at times in cauliflower-like or warty aggregations which contain $C_{11}H_{22}O_{11}$. The hydrous body easily parts with its water at 100° in a

ourrent of dry air. The anhydrous body is but slightly soluble in strong ethyl alcohol; it is more soluble in methyl alcohol. The hydrous body dissolves more freely in both solvents. Both bodies are very soluble in water, but less so than dextrose. The solution is optically active, and the activity for a solution containing 10 g. in 100 c.c. is 15°-20° less when freshly prepared than after standing. The activity becomes constant in ten to twelve hours in the cold or immediately on boiling (Meissel, J. pr. [2] 25, 120).

The specific rotatory power for dry maltose is $[a]_1 = 154^\circ - 155^\circ$, $[a]_D = 139^\circ - 140^\circ$ at $15\cdot 5^\circ$ in solutions containing 10 g. per 100 c.c. and under (O'Sullivan, C. J. 35, 771; 45, 5); Meissel (J. pr. [2] 25, 114) gives the formula $[a]_D = 140\cdot 735 - 01837 P - 095 T$ to represent the specific rotatory power of dry maltose at 0°, in which P = percentage of maltose in solution and T the temperature of observation. On calculating the value of the sugar in a 10-g. solution at 15·5° from this formula we get $[a]_D = 138\cdot 9$ (v. also Soxhlet, L.c., and Herzfeld, A. 220, 206). The dispersive power, Le. the ratio of $[a]_D : [a]_C$, is 1·262 (Grimbert, J. Ph. [5] 16, 295). A solution of maltose containing 10 g. dry substance in 100 c.c. at 15·5° has a sp. gr. $\frac{1550}{1550} =$

1.0395. Maltose reduces alkaline copper solution. O'Sullivan $(C.\ J.\ 35,\ 771)$ gives its reducing power $K=62.5,\ i.e.\ 62.5$ parts dextrose reduce as much copper oxide as 100 parts of maltose. Soxhlet $(\hat{J}. pr. 21, 227-317)$ says 0.5 g. maltose in 1 p.c. solution = 64.2 c.c. undiluted Fehling solution (1 c.c. = 005 g. dextrose), i.e. K = 64.2, and 67.5 c.c. if the solution is diluted with four times its volume of water, i.e. K=67.5. He further states that 100 parts of dry maltose = 113 parts Cu, hence 141 parts CuO; from this, we have K = 63.94. There appears to be fair evidence that the K varies within certain limits according to the mode of manipulation, but when we see that the K should be 63.17 if it be supposed that 1 molecule malfose reduces 6 molecules CuO, and that the observed numbers closely approach this, we may take it that this is the true number when errors of manipulation are avoided. If the Cu2O be separated, the filtrate treated with acid gives a further reduction with Fehling's solution which, if added to the first, equals the reduction of dextrose (Herzfeld, A. B. 589, 220). Alkaline mercuric cyanide solutions are also reduced by maltose. Copper acetate is not reduced by it (Barfoed, Org. Analysis, 214); dextrose reduces this reagent. When maltose reduces copper oxide, glycollic and a mixture of acids of unknown composition are produced (Habermann a. Hönig, M. 5, 208).

Maltose is hydrolysed to dextrose according to the equation $C_{11}H_{21}O_{11} + H_{21}O = 2C_{2}H_{12}O_{2}$ by the following reagents: the mineral acids and many organic ones; pancreatic secretion and portions of the small intestine (Brown a. Heron, C. N. 42, 63; Bourquelot, C. R. 97, 1000 and 1822); a ferment developed in Aspergillus niger and in Mucor mucedo; the former contains also a ferment capable of inverting sucrose, the latter yields only the one (Bourquelot, Lo.). Under the action of ordinary beer yearts maintenance of the second contains a second con

ose ferments, i.e. is broken down into carbonis acid, alcohol, &c., apparently without being previously inverted. Other organisms yield lactic acid and other products; v. FERMENTATION.

Maltose withstands the hydrolytic action of sulphuric acid with five times the power of sulrose; 3 hours' digestion with a 3 p.c. solution gives complete inversion (Meissel, l.c.). 0.5 p.c. solution of lactic acid does not hydrolyse it, even at 110°; 1 p.c. oxalic acid acts at that temperature; carbonic acid at 100°, and under a pressure of six atmospheres, is without action (Bourquelot, J. de l'Anat. et de la Physiol. 22, 161-204; Urech, B. 18, 3074).

Nitric acid converts maltose into saccharic acid and finally oxalic acid. Chlorine does not act on it as energetically as it does on dextrose or sucrose; the product is neither gluconic nor glycollic acids (Meissel, l.c.). Herzfeld (B. C. 1883) obtained an acid which he called maltonic acid, by the action of bromine on maltose; this is probably identical with Fischer and Meyer's (B. 22, 194) maltobionic acid C₁₂H₂₂O₁₂, which they prepared by acting on maltose in aqueous solution with bromine in the cold for two or three days. This acid is broken down into dextrose and gluconic acid by digestion with sulphuric acid. Treated at 110° with acetic anhydride and acetic acid, maltose yields monacetyl maltose $C_{12}H_{21}(C_2H_3O)O_{11}$ (Yoshida, l.c., a. Steiner, G. N. 43, 52); with sodium acetate and acetic anhydride the octacetyl derivative C12H14(C2H3O)5O11 is produced, the optical activity of which is $[\alpha]_D = 81 \cdot 18^\circ$ (Herzfeld, A. 200, 206). With benzyl chloride it yields penta-benzyl maltose, m.p. 110°-115° (Skraup, M. 15, 359).

Sodium $C_{12}H_{21}NaO_{11}$, calcium $C_{12}H_{22}SrO_{11}H_{2}O$, and barium $C_{12}H_{22}SrO_{11}H_{2}O$, strontium $C_{12}H_{22}SrO_{11}H_{2}O$, and barium $C_{12}H_{22}SrO_{11}H_{2}O$ maltose are prepared as easily decomposable amorphous precipitates when alcoholic solutions of maltose and the corresponding bases are mixed (Herzfeld, *l.c.*). Compounds with the alkaline chlorides or bromides have not been prepared.

When 1 part maltose, 2 parts phenylhy-drazine hydrochloride, 3 parts sodium acetate, and 15 parts of water are heated together for 1½ hours, phenylmaltosazone crystallises out on cooling in fine yellow needles, m.p. 190°–191°. The equation C₁,H₂,O₁, +2N,H₂,C,H₃=C₂,H₂,N₁,O₂+2H₂O+H₃ represents the reaction. Only 30 p.c. of the maltose employed is obtained as osazone (Fischer, B. 17, 583). With y-diamido-benzoic acid, maltose yields malto-y-diamido-benzoic acid according to the equation

The body crystallises in white microscopic needles or narrow plates; its barium salt is a gummy mass (Griess a. Harrow, B. 20, 2212).

Isomaltose. Fischer (B. 23, 8687) prep ared a saccharon by the polymerisation of dextrose. Previous attempts in this direction had been made by Musculus (Bl. 18, 66), Muscu us a Meyer (C. R. 92, 528), Hönig a. Schuber M. 7, 455), and they obtained by the action of strong sulphuric acid a dextrin-like body $C_0H_{10}O_{20}$

SKA SUGAR.

which slightly reduced Fehling's solution, did not ! ferment with beer yeast, and was reconverted into dextrose by the action of dilute sulphuric acid. Grimaux a. Lefèvre (C. R. 103, 146) obtained a like result by evaporating in vacuo dextrose with dilute hydrochloric acid. Gautier (Bl. 22, 145) obtained a body $C_{12}H_{22}O_{11}$ by the action of hydrochloric acid on an alcoholic solution of dextrose; this body reduces Fehling's solution but slightly, does not ferment with beer yeast, and could not be reconverted into dextrose. Grimaux and Lefèvre considered that in their product they could detect maltose by the osazone. Scheibler a. Mittelmeier (B. 23, 8075; 24, 301) isolated an unfermentable syrup from commercial glucose which reduces Fehling's solution and yields an osazone $C_{2}H_{2}N_{*}O_{p}$, m.p. 152°-153°. They find it is only produced when the heating with acid has been prolonged, and that it may be prepared by the action of acids on dextrose. This body has been previously named gallisin (Cobenzl, Roseneck a. Schmitt, B. 17, 1000 and 2456; Anthon, D. P. J. 151, 213; Mehring, Deutsche Vierteljahrsschrift für öffentl. Gesundheitspflege, 14, Heft 2). Fischer's substance also yielded the same osazone, m.p. 150°-153°; he calls the body isomaltose, and prepares it as follows: One hundred g. glucose (commercial dextrose) are digested with 400 g. hydrochloric acid solution sp. gr. 1·19 at 10°-15° for 15 hours. Alcohol throws out of the solution a small precipitate, which is not formed if the temperature of the reaction is kept below 10°. To the clear solution an excess of ether is added, when a colourless amorphous precipitate is obtained which is filtered out and washed with a mixture of alcohol and ether. This body is dissolved in water, neutralised, boiled to expel alcohol and ether, and fresh beer yeast added. After 18 hours all the dextrose is destroyed (?); the solution has still a high reducing power, and contains isomaltose and other bodies.

The isomaltose is separated as osazone; the solution is heated with phenylhydrazine acetate in the water-bath for 11 hours. A little glucosazone separates and is filtered out, and on cooling the filtrate deposits a yellow precipitate consisting of a mixture of glucosazone and isomaltosazone; the mother-liquor, by further heating and similar after-treatment, yields more osazone. The whole of the osazone obtainable is boiled with 100 c.c. water and the solution filtered, the filtrate contains isomaltosazone, which is deposited on cooling in needles; $2\frac{1}{9}g$, of this are obtained from 100 g. glucose, the actual yield is, no doubt, considerably higher than this. By the action of hydrochloric acid the osazone is converted into the osone, which, when boiled with 4 p.c. hydrochloric acid, yields glucosone and glucose.

Lintner claims to have found isomaltose amongst the transformation products of starch by diastase (Woch. Brauerci, 9, 245), and in wort and beer (Zeit. ges. Brauw. 1891, 281), but it is very doubtful if this is the same body as that above described. Schiffer (C. C. 1892, 2, 825) has also isolated isomaltose from the diastase transformation products of starch. But the whole evidence is unsatisfactory, as the factors upon which the identity of the bodies can be recognised are not stated. Lintner and Düll (Zeit. ges. Brauw. 1892, 145) prepare it as fol-

lows: 250 g. potato starch are mixed with 500 c.c. diastase solution at 55° containing 0.5 g. diastase (J. pr. 34, 378) and 2 litres water at 75°C. After complete solution another 0.5 g. diastase is added, and the reaction allowed to proceed for three hours at $65^{\circ}-69^{\circ}$. $[a]_{D} = 170^{\circ}$. for matter in solution. The solution is evaporated to a syrup, saturated with 80 p.c. alcohol, and poured into hot alcohol. Sufficient alcohol must be used so that every 100 parts of 80 p.c. alcohol do not contain more than 10 pts. dry substance. After cooling, the clear solution is decanted and the alcohol distilled off. The residue is diluted to a 20 p.c. solution and yeast added in order to destroy the maltose; this is found to take place in about 20 hours. The fermented solution is filtered, decolourised with animal charcoal, evaporated to a syrup, and precipitated with 85 p.c. alcohol; there must be 100 c.c. of 85 p.c. alcohol for every 5 g. of dry substance. The solution is evaporated and the syrup treated in the same way, but with 99 p.c. alcohol and so that 100 c.c. of alcohol are present for every 3 g. dry substance. The clear alcoholic solution contains isomaltose and but a trace of dextrin, which may be removed by fractionating with alcohol. In this way 20 p.c. of the starch is obtained as isomaltose.

Lintner (Zeit. ges. Brauw. 1892, 6) finds the reducing power of iso-maltose to be 84 p.c. of that of maltose, i.e. K = 53.1, and its optical activity to be $[a]_D = 139^\circ$. He has not been able to crystallise it, and finds it under certain conditions fermentable by yeast and converted by diastase into maltose (Zeit. ang. Ch. 1892,

Trehalose. Mycose C₁₂H₂₂O₁₁.H₂O.
Occurrence.—It has been isolated from ergot of rye (Wiggers, A. 1, 173; Mitscherlich, 56, 15); trehala-manna, the hollow cocoons of the larvæ of an insect (Larinus maculatus) (Berthelot A. Ch. [3] 53, 232; 55, 272 and 291); and from various fungi (Müntz, C. R. 76, 649). Berthelot at first considered it a new sugar and called it trehalose, but afterwards found it was iden. tical with the mycose of Mitscherlich, and the Saccharum spermodiæ of Wiggers.

Preparation. - Any one of the materials mentioned is extracted with boiling alcohol of moderate strength; the alcohol is distilled off the clear solution. The residue is taken up with water and precipitated with basic lead acetate. The precipitate is washed with water and pressed: it is then suspended in water and submitted to a current of H.S. The clear filtrate from the lead sulphide is evaporated to a syrup, when the sugar crystalliscs and can be purified by recrystallisation. I may say that I do not find this mode of treatment answer very well; the filtrate from the PbS is, no doubt, clear, but the precipitate with the lead salt is bulky and unwieldy. I much prefer in this case, as in others of the same kind, fractional precipitation with alcohol; a few experiments will show the strength of alcohol best suited to holding or precipitating the sugar. (See also Apping.)

Properties.—The sugar crystallises in rhombs (C₁₂H₂₂O₁₁H₂O); it gives up its water at 100°, m.p. 109°; it is sweet, easily soluble in water and boiling alcohol, insoluble in ether. Specific rotatory power in squeous solutions

 $[a]_j = 199^\circ$ (Berthelot); $[a]_j = 192 \cdot 5^\circ$ (Mitscherlich); $[a]_D = 197 \cdot 28^\circ$ (Apping). These factors are unsatisfactory, and cannot be relied on to identify the sugar. It does not reduce Fehling's solution. Acids convert it very slowly into dextrose (Berthelot), there being no other product; but considering that five hours are required for complete hydrolysis, it is not possible that only pure dextrose could be formed. With strong nitric acid it yields a nitro- compound; with weaker acid no mucic acid is formed, but saccharic acid and finally oxalic acid. With acetic and butyric anhydrides it yields compounds identical with those produced from dextrose. Maquenne (C. R. 112, 947) says acetic anhydride yields $C_{12}H_{14}(C_1H_2O)_*O_{11}$. Alkalis do not act on it. On adding basic lead acetate, or an ammoniacal solution of the acetate, to its solutions a lead compound is precipitated. It appears to slowly undergo alcoholic fermentation in contact with beer yeast, but this has not been established with certainty. Phenylhydrazine does not form a compound with trehalose (Fischer, B. 17, 583).

Agavose C₁₂H₂₂O₁₁ (?) is obtained from the

juice of Agava americana; it is crystalline, soluble in water, and optically inactive (?). It is hydrolysed to a sugar or mixture of sugars $[a]_j = -14\cdot 4^\circ$. It reduces Fehling's solution; $K = 62\cdot 5$, agreeing nearly with maltose in this respect. It does not yield mucic acid on treatment with nitric acid. It is probably fermentable under the influence of some saccharomyces and yields alcohol, &c. (Michaud a. Tristan, Am.

Cyclamose $C_{12}H_{22}O_{11}$. A sugar obtained from Cyclamon europeaum, having a lavorotation $[a]_D = -15 \cdot 15^\circ$ or $-11 \cdot 4^\circ$; it is hydrolysed by dilute acids, when the lavorotation increases to

 $[a]_{\rm D} = -66.54^{\circ}$ (Michaud, C.N. 53, 232).

Parasaccharose $C_{\rm D}H_{\rm c2}O_{\rm H}$. This, together with another uncrystallisable sugar, is said to be obtained from cane sugar by the action of a yeast (Jodin, C. R. 53, 1252). It crystallises easily, and is easily soluble in water and difficultly in alcohol. It is dextrorotatory, having $[a]_1 = 108^\circ$, and it reduces Fehling's solution; K = 50 (about). Hot dilute sulphuric acid does not act on it, whilst hot dilute hydrochloric acid diminishes the optical activity and increases the K. On long digestion the solution becomes brown, and finally complete decomposition takes place.

Melibiose C₁₂H₂₂O₁₁ is obtained by the careful hydrolysis of raffinose by acids or invertase (see Raffinose). Its specific rotatory power is $[a]_b = +126:8^\circ$. It forms a hydrazide $C_{11}H_{12}O_{12}O_{13}$

a. Mittelmeier, B. 23, 1489). Invertuse converts it into galactose and dextrose.

Tewfikose C₁₂H₂₂O₁₁ occurs in the milk of the gamoose (Bos Bubulus). It is prepared by precipitating the milk by 4 p.c. acid mercuric nitrate (Wiley, Am. 6, No. 5 (?), neutralising the filtrate with NaHO, filtering out the precipitate, separating the mercury from filtrate by H.S. and concentrating the slightly acid solution to the crystallising point. A slight precipitate formed during evaporation must be separated. It is purified by two or three recrystallisations.

reduces Fehling's solution; K=73.6, hence less than lactose; if 7 molecules CuO were reduced by 1 molecule of sugar, the K would be 73.4, a near approximation; and D = 3.94 for the crystals, hence they are anhydrous. Acids hydrolyse it very easily, the only product being dextrose (Pappel a. Richmond, C. J. 1890, 758). The substance is, no doubt, an '-on' sugar C12H22O11, and is, like amylon, di-dextrose, and should not therefore yield mucic acid on treat-ment with nitric acid.

(c) Trihexoses. Raffinose C₁₈H₂₀O₁₆5H₂O, first obtained from a Tasmanian Eucalyptus manna by Johnston (C. J. 1, 159). This was the melitose of Berthelot (A. Ch. [3] 46, 66), who now says (C. R. 103, 533) that this term should be applied only to a loose combination of raffinose with eucalin, which is decomposed by re-crystallisation. From the evidence it would appear that the body first described as melitose was impure raffinose, and that the impurity even was not eucalin. It occurs also in cotton seed (Berthelot, *l.c.*; Ritthausen, *J. pr.* [2] 29, 357; Böhn, *J. pr.* [2] 30, 37); in beetroot (Loiseau, *C. R.* 82, 1058; Tollens, *A.* 232, 169; *B.* 18, 26; Rischbieth a. Tollens, *A.* 232, 172; *B.* 18, 2611); in beet juice (v. Lippmann, B. 18, 3087); in barley (O'Sullivan, Sumbal, B. 18, 3091; in bate-budg Richardson a. Crampton (B. 19, 1180); and again in Eucalyptus manna (Tollens, A. 232, 201); probably also in Soja beans. Loiseau considered it a product of the refining process, but v. Lippmann that it was ready formed in beet juice.

Preparation. - A molasses containing a fair quantity of railinose is selected, and the chief part of the cane sugar removed as monostrontium saccharate; on heating the solution raffinose and cane sugar bistrontium saccharates are precipitated. The compounds are decomposed by CO₂ and the sugar solution obtained again precipitated with strontia, when the cane sugar is precipitated as monostrontium saccharate, and raffinose remains in solution and may be purified by crystallisation (Scheibler, B. 18, 1409). Raffinose may be extracted from cottonseed cake and Eucalyptus manna by alcohol, and purified by crystallisation. See also Tollens (i.c.); Tenne (Zeit. d. Ver. 31, 795); Schaaf (Z. V. 33, 699); Wolff (Deutsche Zuckerind., 1887, 1413); Berthelot (l.c.); Lindet (C. R. 110, 795); Gunning (C. C. 1891, ii. 798).

Properties .- Rassinose crystallises in cauliflower - likes segregations consisting of thin microscopic rhombic prisms, which contain $C_{18}H_{32}O_{16}.5H_{2}O$. The $H_{2}O$ is in greater part eliminated in a vacuum over sulphuric acid, and the remainder easily at 100° (O'Sullivan). If heated too quickly it melts, and then cannot be dried without decomposition. Berthelot obtained crystals containing 6H₂O (C. R. 109, 548; Scheibler, B. 18, 1779; Rinne in Rischbieth Dissert. über Raffinose, Göttingen, 1885). It is easily soluble in water, very slightly in strong alcohol, and slightly in methyl alcohol, being much more soluble than cane sugar in this solvent. The dry sugar melts at 118°-119° (Scheibler, B. 19, 2868). Its solutions are optically active, the specific rotatory power of crystallised raffinose for the D line being [a]n = The solutions are dextrorotatory, $[a]_0 = 48.6^\circ$; it | 104.5° in 10 p.c. solution; $[a]_1 = 114.7^\circ$ or $[a]_1 = 114.7^\circ$

185.1° for the dry sugar. O'Sullivan observed $[a]_i = 185.8^{\circ}$. No bi-rotation has been observed. It does not reduce Fehling's solution. D = 3.712(Tollens, B. 18, 2616), but this is due to some misunderstanding; D = 3.956 (O'Sullivan, C. J.

1886, 70).

Action of acids. Hot dilute acids hydrolyse raffinose; galactose, lævulose, and probably dextrose are formed (Hädicke a. Tollens, Z. V. 37, 17; A. 238, 308; Beythien a. Tollens, A. 255, 214; Maquenne, C. R. 112, 799). By very careful hydrolysis, Scheibler a. Mittelmeier (B. 22, 1678) have obtained a saccharose and lævulose as the products of the reaction; the saccharose is a new body, which they have called melibiose (q. v.). The mixture of saccharose and lævulose has a specific rotatory power $[a]_D = 50^\circ$. Complete inversion of raffinose takes some hours. Invertase also hydrolyses raffinose (O'Sullivan). The products of hydrolysis are at first lævulose and melibiose (Scheibler a. Mittelmeier, B. 22, 3118), and melibiose is slowly acted on. When heated for some time with sulphuric acid, lævulinic acid is a product (Rischbieth a. Tollens, A. 232, 195).

Action of alkalis. By boiling aqueous solutions of strontia and raffinose, di-strontia raffintions of strontia and raffinose, di-strontia raffinose C₁₆H₂₂O₁₆(SrO)₂·H₂O is produced. Other compounds with baryta C₁₈H₂₂O₁₆·BaO, lime C₁₈H₂₂O₁₆·3CaO.2H₂O, lead oxide C₁₈H₂₂O₁₆·3PbO, and soda, C₁₈H₃₁NaO₁₆ and C₁₈H₃₁NaO₁₆·NaOH, have been prepared (Beythien a. Tollens, B. 22, 1047; A. 255, 195; Rischbieth a. Tollens, A. 232, 172)

232, 172).

Oxidation .- Nitric acid oxidises raffinose, producing 30 p.c. mucic acid, also saccharic and oxalic acids.

Fermentation .- Rassinose is slowly fermented by beer yeast (Rischbieth a. Tollens, A. 232, 242; Tollens, A. 232, 169; O'Sullivan, C. J. 1886. 73). Weak yeast only partially ferments it (Tollens, I.c.; Berthelot, C. R. 109, 548); the melibiose being with difficulty hydrolysed and fermented.

With phenylhydrazine a compound is formed, m.p. 187°–189° (Rischbieth a. Tollens, l.c.).

Melezitose C₁₈H₃₂O₁₈.2H₂O is obtained from Persian manna, a product of Alhagi maurorum (DC.), it crystallises in rhombic prisms, m.p. 147 -148° (when anhydrous); the specific rotatory power of the anhydrous body is $[a]_D = 87.7^{\circ}$. On inversion it yields turanose and dex-87.7°. On inversion it yields turanose and dextrose. Turanose C₁₂H₂O₁₁ [a]_D = 65°-68°, yields dextrose by the further action of acid (Alekhin, J. R. 21, 407).

(d) Hexahexoses.
Gentianose C₂₄H₂₂O₂₁. Obtained by A. Meyer
(H. 6, 185), from the root of Gentiana lutea, by extraction with alcohol, precipitation with ether and re-crystallisation from alcohol. It has a sweet taste, dissolves easily in water, m.p. 210°, does not reduce Fehling's solution, and ferments with yeast. It is hydrolysed by dilute acids; before inversion the optical activity is [a]_D = 83·6°; after, it is 20·2°, and has a reducing power equal to that of dextrose. Strong sulphuric acid chars it, like cane sugar.

Stachyse is obtained from the root of Stachys tuberifera. It has a sweet taste, is destrorotatory, having $[a]_b = 148 \cdot 1^o$ in 9 p.c. solution. It forms triclinic crystals. When in-

verted it yields galactose, dextrose, and imvulose. Its formula appears to be $C_{sc}H_{s}O_{32}+6H_{3}O$ (Planta a. Schulze, B. 23, 1692; 24, 2705), the products of the hydrolysis being the same as those of raffinose.

QUALITATIVE AND QUANTITATIVE DETERMINATION . OF SUGARS.

If the material to be examined is a solution, it must be made neutral, clear, and colourless if it is not already so.

If the material is a dry substance, it must be ground fine. If not sufficiently dry to admit of grinding, it must, if possible, be dried in vacuum over sulphuric acid, or, where this is not possible. in the open, at a low, gradually increasing temperature.

The finely-ground substance is extracted with alcohol sp. gr. 860-880. The solution is neutralised and the alcohol distilled off. The residue is taken up with water. The examination then comes under the head of a solution, and the treatment is the same.

The solution is turbid and coloured after neutralisation. The turbidity may be removed by simple filtration; if not, a little aluminium hydroxide (prepared by precipitating a solution of alum with excess of ammonia and washing free from ammonia and sulphuric acid) may be employed. A little (well washed) Swedish filter paper-pulp is at times found useful. The turbidity and colour may be removed together by animal charcoal, lead sulphide, barium sulphate, &c. Animal charcoal, either prepared from blood or bones, the former by preference, thoroughly extracted with hydrochloric acid and washed free therefrom, is best employed in all cases of investigation. The crude substances are employed to remove the colour, &c., from sugar syrups in the manufacture of refined cane sugar. These decolouring agents must always be used in the least possible quantity, and with the understanding that the charcoal especially is capable of taking up some sugar as well as Dried, freshly-made bone celouring matter. charcoal does not take up more than .006 p.c. of its own weight from pure cane-sugar solution (Casamajor, C. N. 41, 66). In quantitative work, when the decolourising agents have to be used it is well to have a knowledge of the influence of the agent on the sugar or sugars under examination. Charcoal retains sugar, other substances influence the optical activity. Part of the sugar is again given up on washing the agent with water, or the agent is placed on a filter and a portion of the solution to be examined passed through it and rejected before the por-tion intended for examination is collected. This is done on the supposition that the charcoal is sooner saturated with sugar than with colouring matter.

Having thus the sugars in clear solution, the means at our disposal for identification are:-

1. Taste of solution.

- 2. Form of crystals and melting-point thereof. Depression of the freezing-point (Raoult's method of determining molecular weights).
- 4. Specific rotatory power.

5. Reducing power.

- 6. Action of unorganised ferments: enzymes.
- 7. Action of organised ferments.

- 8. Action of acids.
- 9. Action of alkalis.
- Action of phenylhydrazine, and melting-points of the resulting osazones and hydrazides.
- 1. The solution tastes sweet if a sugar is present. It must not be forgotten, however, that some other bodies are also more or less
- 2. On evaporating this solution (best in a vacuum) to a syrup, if there is no preventive material present, crystallisation takes place. The microscopic appearance of the crystals will often be sufficient to identify the sugar; indeed, the habit of crystallisation will often suffice. substance or substances may be present which altogether prevent the crystallisation of the syrup, although it may contain a crystallisable sugar. This substance may be an inorganic or organic salt, or another body, or, indeed, another sugar. Treatment with strong or absolute ethylic or methylic alcohols may at times eliminate some or the whole of the substances preventing the crystallisation, and dissolve the sugar in so clean a state as to admit of the formation of crystals on concentration.

3. Depression of the freezing-point (Raoult's method). For references to Raoult's work see Victor Meyer, B. 21, 536; Auwers, id. 701; Tollens a. Meyer, id. 1566; and Brown a. Morris, C. J. 1888, 610. When crystals are obtainable from the solution as described above, a determination of the molecular weight by this method will decide to which group it belongs: a hexose or a pentose, a dihexose or dipentose, a trihexose. In the recorded observations water of crystallisation appears not to have received proper attention. Tollens a. Meyer record observations for dextrose C₈H₁₂O₆, so do Brown a. Morris. Water of crystallisation is not taken into account; the former treat of $C_{12}H_{22}O_{11}.H_1O$ for lactose, the latter omit the H_2O , while both employ crystallised raffinose $C_{13}H_{22}O_{12}.5H_2O$, mol. = 594, with the result that T. a. M. find the observed molecular weight between 544 and 644, and B. a. M. between 518 and 533. In these experiments with raffinose and lactose, it is not possible to say whether it is intended that the crystallisation water functions with the solid sugar or with the water; the calculations make it function with the sugar, but the results, as might have been expected, are unsatisfactory-it does not function with the sugar. It is perfectly clear that water of crystallisation of a sugar must be looked upon as water in observations with this method-that the quantity of dry sugar should be the factor dealt with. If the crystals contain water of crystallisation it should be determined and allowed for. A determination of the D will give some information as to whether a dry sugar or one containing water of crystallisation is being dealt with. The D of the different sugars in the dry state is given under each sugar. Between 8 and 15 g. dry substance is dissolved in water and the solution made up to 100 c.c. at 15.5°. A determina-tion of the specific gravity of this will give a means of calculating the D, and the number of g. of water to substance employed in the solution. About 60 c.c. of this solution are introduced into a thin glass (120 c.c.) beaker. The

mouth of the beaker is loosely closed with an indiarubber plug, in which three holes are bored. One of these, in the middle, admits of the introduction of a thermometer; the second, at the side, carries a stirrer, of very thin glass rod or platinum, best in the form of a flat coil, so that when the stirrer is moved up and down in the liquid the thermometer will be in the middle of the coil; and the third, also at the side, to admit of the introduction of a small solid particle of the frozen solution or of ice. The thermometer must be graduated for 2° or 3° above and below 0° to the 20th of a degree. By means of a telescope, if the divisions are open, and they should be so, readings to '005° can be made with a fair amount of accuracy. The beaker thus charged and fitted is placed in a freezing mixture of ice and salt—which should not be at too low a temperature, -4° to -5°, not more than 2°-3° below the freezing-point of the solution—contained in a strong beaker of 500-600 c.c. capacity. In a short time the temperature in the inner beaker will be observed to sink below 0°, and, on rapidly moving the stirring rod up and down, to go gradually lower and lower until a point is reached when the solution begins to freeze. This may be accelerated by adding a particle of the solution previously frozen; when freezing begins the mercury of the thermometer rapidly rises and soon becomes stationary. This is the freezing-point of the solution c, and is the observation upon which the molecular weight of the substance employed is calculated.

$$\mathbf{M} = \frac{19}{\mathbf{A}}, \qquad \mathbf{A} = \frac{\mathbf{c} \times \mathbf{y}}{\mathbf{x} \times 100},$$

x = g. substance; y = g. water, and 19 is a number calculated by Raoult for water as a solvent from observations with well-defined compounds. examples, Brown a. Morris (l.c.) with a solution containing 8.258 g. sucrose and 94.93 g. water observed a freezing-point $c = 0.490^{\circ}$, thence

$$M = \frac{.49 \times 94.93}{8.258 \times 100} = 337.5$$
. $C_{12}H_{22}O_{11} = 342$.

Hence, if an unknown sugar were under observation there would be no doubt left as to the molecular weight. O'Sullivan (C. J. 1890, 59) observed for arabinon: sp.gr. sol. 1.02554, y = 96.088 g., x = 6.466 g., $c = 0.535^{\circ}$; thence $96.088 \times .535$ $19 + \frac{96.088 \times .535}{6.466 \times 100} = 239.2$,

$$19 + \frac{96.088 \times .535}{6.466 \times 100} = 239.2$$

the molecular weight of the new sugar. A dipentose requires 282. The indications agreed with further confirmatory observations. the solution contains more than 12 g. per 100 c.c. the results are low; with most sugars a solution containing from 5 to 8 g. substance per 100 c.c. gives the best results, and with more dilute solutions the results are again low. Raoult's latest observations (C. R. 114, 264) for sucrose, made with apparatus constructed to meet the exact requirements of the case, the concentration of the solution being 5.839 g. sucrose in 100 g. water, work out M = 323, against 342, the true molecular weight. The results are, even under the best conditions, low; but the indication is sufficiently good to enable us to decide to which group the sugar we are dealing with belongs. If, instead of the factor 19, 19.8 were substituted, the results would agree with the accepted molecular

SUGAR.

weight of sucrose, and it is probable that this number or 20 will be finally decided upon as the constant.

4. Specific rotatory cower. If the form of the crystals or their habitat does not indicate the sugar present, a determination of the specific rotatory power may give the desired informa-tion. This is the quantitative expression of a property possessed by the sugars in common with many other substances. When light from any source is examined through a Nicol prism-i.e. polarised—no change is evident; but if the light, after passing through one prism (the polariser) is examined by another, it is found that in certain positions of the examining prism or analyser, as it is called -no light passes. If the analyser is made to carry an index, and is so mounted as to rotate with its axis at right angles to a disc graduated to degrees, it will be found that, if the position of the two prisms is so arranged that the index is at 0° on the graduated circle when no light passes, light will pass on the least rotation of the analyser to the right or left, and if the movement is continued another position is found on the disc in which the light is again cut off. This is at 180°, so that the circle should be graduated to 180° right and 180° left. Now, if a cell or tube with flat glass caps be filled with a solution of, say, sucrose and introduced between the two Nicols, and the source of light be a Bunsen burner flame coloured yellow with sodium chloride, when the index of the analyser is at 0° it will be observed that the light passes, and that on rotating the analyser a certain number of degrees to the right a point is found (which is not 180°) at which the light is cut off; and if note be taken of the exact number of degrees, and the analyser rotated further, it is found that the light is not again cut off at 180°, but the same number of degrees beyond 180° as the first extinction was beyond 0°. This is the optical activity of the sugar or. This is the optical activity of the sugar solution. It is the power of rotating the plane of polarisation of the ray passing through the polariser so as to admit of its passing through the analyser when it would not pass had the sugar solution not been introduced. The amount of rotation of the analyser to again find the direction of the plane of polarisation, as indicated by the index on the graduated disc, is the measure of the activity of the sugar solution, and the direction of the movement of the index is the direction in which the rotation has taken place; in the present case (i.e. when the index is moved on the disc in the direction of the hands of a watch) right or +. If the sugar solution be now hydrolysed by dilute acids or invertase, and again introduced between the Nicols, it is found that the analyser must be rotated to the left in order to find the position of extinction—i.e. the direction of the plane of polarisation of the rotated ray. This is left rotation, and is indicated by the sign -. On further rotation of the analyser light again passes, and finally there is a second extinction as far beyond 180° as the first extinction was beyond 0°. From this it is clear that the second reading may indicate right-handed rotation as well as left. Say the first extinction was 10° left of 0° (-10°), the second would be +170°, 10° less than 180°; then the activity might be

-10° or +170°. On diluting the solution say one-half, if the activity is — the readings will be -5° and $+175^{\circ}$, if + they will be $+85^{\circ}$ and -95°. The exact measurement of this activity has been the subject of much investigation, and many plans have been devised to facilitate the operation. It is, however, beyond the scope of this article to deal more fully with the subject (for details see Das optische Drehungsvermögen organischer Substanzen, Landolt, Braunschweig. 1879, Engl. Trans.; Handbook of the Polariscope, Macmillan & Co., 1882; Watts' Dictionary, Suppl. 3, art. Light. In the experiments above described the light of a sodium flame was employed; it was observed early in the investigation of the phenomena that readings sufficiently accurate, especially if the amount of activity was small, could not be obtained. Hence other devices were introduced. In the literature we find the activity expressed [a]_R, [a_j], or [a]_D and [a]_B, [a]_O, [a]_{Li}, &c.
[a]_R values are not now used. They were

[a]_R values are not now used. They were obtained by employing white light, and interposing between the polariser and the source of light a plate of red glass. They are of no value for our purpose, and may be neglected.

value for our purpose, and may be neglected.
[a], values are frequently used, but unless they are referred to a definite standard they, too, are of no value. If any ordinary source of white light be substituted for the sodium flame in the experiments above described, it will be observed that on rotating the analyser to find the effect produced by the sucrose solution no position of the analyser can be found in which all the light is cut off, but at one stage marked blue light passes, and, on further rotation of the analyser, red. This is due to the fact that the sugar solution acts unequally on the different rays of which the beam of white light is composed, the red rays being rotated least and the violet most, so that when the analyser is rotated the ray the plane of polarisation of which is rotated least is first cut off. The first cut off rays are the red, the complement of those cut off passing, the dominant being blue; on further rotation the carefully it is found that the transition from the blue to the red is well marked; this is the a, value; it is the, so-called, transition tint, the ray complementary to the median yellow, jaune moyen; hence a_j. For the same strength of sugar solution the position of the analyser is not the same for every source of white light. The stage at which the transition appears with candle-light is different from that at which it appears with gas-light; the stage in this case differs again from that obtained with the electric light, and even the position for direct sunlight differs from that of the light reflected from a cloud. Hence, when a pair of Nicols are employed as described above, even when the source of light is given, a cannot be looked upon as a standard value. This value has, however, been given to it by the French instrument makers.

Soleil invented an instrument with which lamp- or gas-light is employed (afterwards improved by Duboscq, and known as the Soleil-Duboscq (see Watts' Dictionary, 1st ed. 3, 674, a. Suppl. 8, 1199), by which the activity of a solution is measured by divisions of a sole instead of degrees; 100 of these divisions were

made equal to the amount of rotation promade equal to the amount of research pro-duced by 1 mm. quartz for the a; this was considered to be 24°. Of course, if this is taken as a standard it is of full value; it may not be truly α_1 even for the quartz, but it is α_1 referred to a definite measure, the 100 divisions of the instrument being 24°. This was complicated by the fact, since pointed out by Scheibler, that quartz from different sources has not the same optical activity; hence we have various observers giving different values for the amount of sucrose in 100 c.c. solution, which when observed with the Soleil-Duboscq instrument, in a tube 200 mm. long, equals the activity of 1 mm. quartz. If, however, we look upon the 100 divisions of the instrument as = 24° a_j, we have a standard value for the expression. I believe this is the value given to it by the French observers. The writer employed it in the same way. Another instrument of much the same construction is the Soleil-Ventzke-Scheibler (v. Watts, l.c.). In this the 100 divisions of the scale are made to represent the activity of 26.048 g. saccharon in 100 c.c. solution; we have only to inquire as to the [a] and [a] of cane sugar to arrive at a value in degrees of the 100 divisions for these two expressions. From these two factors we get 100 divisions, Soleil-Duboseq = 24° a, and $21.67^{\circ}a_{\rm p}$, and 100 divs. S.V.S. = 38.34° a, and $34.55^{\circ}a_{\rm p}$. The angular value or any other instrument in use in which the scale is given in divisions can be calculated for a or a by ascertaining the number of divisions required to compensate a solution of sucross containing 10 g. in 100 c.c. at 15.5°, and taking the apparent specific rotatory power of the sugar for the concentration to be $[a]_1 = +73.8^{\circ}$ and $[a]_p = 66.6^{\circ}$, the value of the divisions in degrees for both rays can be calculated. The direction of the rotation is indicated in these struments by the direction of the movement of the 0 point to find the compensation necessary; if from left to right it is right or +, if in a contrary direction left or -. With the other instruments in use sodium flame is the source of light employed; the readings are therefore ap. The scale is a circle graduated to degrees on a disc, beginning with 0 at the top and graduated in half degrees and degrees to 180° to the right, and in the same way to the left. The analyser rotates in the axis of this disc, and carries an index with vernier, which admits of readings being made to minutes. The arrangement is such that the polarised ray before en-tering the active solution has the appearance of a circular disc divided into halves by a perpendicular diameter. The position of the plane of polarisation is not the same in both semidiscs so that when the light is completely out off at one side it passes at the other, and vice versa. To find these positions the analyser has to be rotated several degrees, but between the two positions of complete cut off there is a position of the analyser in which the two semi-discs are equally illuminated; this is a wellmarked position distinctly ascertainable. The 0 point of the index and of the graduated scale are made to correspond exactly with it. It can always be found to within less than a minute. When the active substance is introduced the equality of the illumination of the semi-discs is Vol. IV.

destroyed; the analyser is rotated until it is again restored. The amount of rotation as shown by the graduations gives the activity in degrees and minutes, of degrees and decimals, according to the make of the vernier. These are the half-shadow instruments, of which the Jellet-Cornu and Lourent are examples (see Watts, l.c.). Other devices have been employed to facilitate an accurate determination of the position of the plane of polarisation of the ray before and after rotation; a description will be found in Landolt and in Watts (l.c.). Recently an instrument has been introduced in which the half-shadow contrivance is adopted, white light (a strong gas-flame) being employed. The scale is the same as that of the Soleil-Ventzke-Scheibler instrument; readings with it can be made with great accuracy. It is manufactured by Schmidt & Haensch, Berlin.

When it is necessary to determine the activity for rays of other refrangibility, say for the lithium or the thallium flame, it is only necessary to colour the Bunsen flame with these metals in the same way as in the case of sodium above. The readings are then c₁₁ and α_{Th}. The α_B, α_O, α_D, &c. for any active substance can be found by employing a pair of ordinary Nicols as described above—white light, best a ray of sunlight, being employed—and examining the light after passing the analyser, with a spectroscope. If the positions of the lines of the solar spectrum are marked, the amount of rotation for the active substance introduced between the polariser and the analyser is found, when on rotating the analyser the thickest part of the black band is on the marked position of the line of the spectrum. This is read off on the scale connected with the analyser.

With any of these instruments we can determine the optical activity of a sugar and thus identify it. The sugar is crystallised; it is dried, and 10 g. or thereabouts carefully weighed out. This is dissolved in water, and the solution made up to 100 c.o.' at 15.5°. A portion of this is introduced into a tube of definite length, and an observation made with any of the instruments mentioned above. The formula $[a] = \frac{a_1 \cdot 100}{1.0^{\circ}}$ gives the apparent specific rotatory power for the concentration. a = the angular disturbance observed, l = length in decimetres of tube employed, and c = grams substances in 100 c.c. Let us take an example, 10 g. sucrose, dissolved and made up to 100 c.c. Disturbance observed in a 200 mm. tube with a Soleil-Duboseq instrument, = 61.5 divs.; now for a_1 100 div. = 24°. Then, substituting the values in the above formula we have

$$\frac{61.5 \times .24 \times 100}{2 \times 10} = [a]_{i} = +73.8^{\circ}$$

100 divs. = 21.67° a_D; then

$$\frac{61.5 \times .2167 \times 100}{2 \times 10} = [a]_{p} = +66.6^{\circ}.$$

The scale of the Soleil-Ventzke-Scheibler instrument is so graduated that 100 divisions - the activity of a solution of sucrose containing

This is practically the usual 100 c.o. of a volumetric analysis. For more accurate manipulation see Landola This is, however, unnecessary for the kientification of the sugar—our purpose.

26 048 g. in 100 c.c. in a 200 mm. tube. The apparent specific rotatory power of sucrose in a solution of this concentration is $[a]_D = 66^\circ 33^\circ$ and $[a]_1 = 73^\circ 61^\circ$. Substituting these values in the tormula we get

$$\frac{x.100}{2 \times 26.048} = 66.83;$$

x =the value of 100 divisions in degrees a_D $= 34.55^{\circ}$, and

$$\frac{x' \cdot 100}{2 \times 26.048} = 73.61;$$

 α' = the value of 100 divisions $\alpha_1 = 38.34^{\circ}$.

It is of importance that the values in degrees of the scales of these two instruments should be clearly understood. We find it stated that a quantity of sugar varying from 16:49 to 16:35 g. in 100 c.c. require, in a 200 mm. tube, a compensation with a Soleil-Duboscq instrument = 100 divisions: 16.35 g. is the best-recognised factor; from my observations it is still too high.

y observations it is still too light.

$$\frac{100 \times 24 \times 100}{2 \times 16 \cdot 35} = [a]i = 73 \cdot 39^{\circ}, \text{ and}$$

$$\frac{100 \times 2167 \times 100}{2 \times 16 \cdot 35} = [a]_{D} = 66 \cdot 27^{\circ},$$

figures slightly too low for the apparent specific rotatory power of sucrose for the c, hence 16:35 g. is too high. The number, no doubt, should be 16:28, and this gives factors agreeing well with the observed [a]D and [a], for the c.

A solution containing 10 g. sucrose in 100 c.c. requires a compensation in a 200 mm. tube of 38.5 divisions f a Soleil-Ventzke-Scheibler instrument.

$$\frac{38.5 \times 3834 \times 100}{2 \times 10} = [a]_1 = 73.8^{\circ} \text{ and}$$

$$\frac{88.5 \times 3455 \times 100}{2 \times 10} = [a]_0 = 66.5^{\circ},$$

numbers agreeing accurately with the specific rotatory power for the c. The optical arrangements of these instruments admit of the employment of white light.

If either of the sodium-flame instruments is employed the angular disturbance is introduced directly into the formula. With the 10 g. in 100 c.c. solution of sucrose, the reading in a 200 mm. tube is

 $\mathbf{s_D} = +13.3^\circ$, then $\frac{13.3 \times 100}{2 \times 10} = [a]_D = 66.5^\circ$. The use of this factor is obvious. We have a solution of a known sugar of unknown strength, and want to find the c (g. in 100 c.c.). An observation is made in a tube of known length,

 $a_D \text{ or } a_j$; then $\frac{a.100}{l.c}$ = the determined value of [a]D or [a], a the ray for which the observation is made, and [a] the specific rotatory power for that ray, according to the light employed and

concentration, $c = \frac{a \cdot 100}{[a] l}$

It has been shown that if a solution contains two or more active substances, the observed activity is the algebraic sum of the activities of the constituents. The specific rotatory power of each individual sugar is given in the description of it.

5. The reducing power. As has been stated, most of the sugars possess the power of redu-

cing the oxides of the higher metals and some organic colouring matters. Various propositions have been made to employ this property as a means of qualitatively and quantitatively determining the sugars, and various solutions have been proposed for that purpose; but speaking with many years' experience I may say that they may all be discarded in favour of alkaline copper solution, Fehling's solution; and even with regard to the value of this a great diversity of opinion exists. But there is a general agreement that if the conditions under which it is used are constant the results are constant. For literature see Becquerel, A. Ch. [2] 47, 15; Trömmer, A. 38, 360; Müller a. Hagen, Pf. 23, 221; Neubauer, Fr. 1, 378; Maly, Fr. 10, 383; Seegen, C. C. 1875, 223; Fehling, A. 72, 106; Seegen, C. D. 1818, 225; Feshing, A. I., 100; Claus, J. pr. [2] 4, 63; Neubauer, Ar. Ph. [2] 71, 278; Patterson, C. N. 25, 149; Loisoau, C. R. 1873. 26; Soxhlet, J. pr. [2] 21, 227; Krause a. Städeler, C. C. 1854. 936; Gräger, Fr. 7, 490; Buswitz, B. 11, 1445; O'Sullivan, C. J. 1876, 2, 125; Märcker, C. 7, 699; Brunner, Fr. 11, 32; Bayley, C. N. 37, 211; Allihn, J. pr. [2] 22, 55; Salomon, B. 14, 2711; Digener, Z.V. 31, 349; Salomon, B. 14, 2711; Digener, Z. V. 31, 349; Schwarz, A. 84, 84; Mohr, Fr. 12, 296; Perrot, B. 9, 19; Ulbricht, B. 10, 128; Jean, C.R. 73, 1397; Scheibler, Z. 9, 820; Weil, Fr. 11, 284; Arnold, Fr. 20, 331; Volhard, A. 190, 1; Soldaini, B. 9, 1126; Possoz, C. R. 1874, 721; Pellet, J. Fabra 19, 22; Pavy, C. N. 39, 1004; Löwe, Fr. 9, 20; Vogel, J. Ph. [2] 1, 245; and others of less value. As a result of a study of all this literature, I may say that I have come to the conclusion that if the Fehling's solution is carefully made with pure materials. and em is carefully made with pure materials, and employed as described below, the reducing power of any sugar can be determined with constancy and accuracy, and when the conditions are fulfilled the reduction is molecular—i.e. a definite number of copper oxide molecules are reduced

by a definite number of molecules of the sugar.

Fehling's solution is made as follows:
34.61 g. pure recrystallised copper sulphate are dissolved in 400 c.c. H₂O or thoreabouts, 173 g. sodium potassium tartrate (Rochelle salt), and 74 grams freshly-prepared sodium hydroxide (commercial stick soda) are dissolved to 450 H₂O; when the solution is cold it is gradually added to the copper solution in small portions at a time, so that the pp. at first formed is re-dissolved. When both solutions are mixed the volume is made up to 1 litre. It is very generally stated that this solution does not keep very well. I found it constant in its properties for more than twelve months when kept in carefully-stoppered bottles, sealed with paraffin in a cool, dark place. Some recommend that both the solutions be made up to 500 c.c., kep separately and mixed in equal volumes when re quired for use. This is probably the better plan but unless the solutions are kept in well-stop pered bottles sealed they will deteriorate a badly as if mixed. This solution is used as (a a qualitative test for the reducing sugars.

Redewald a. Tollens (B. 11, 2072) employ 60 g and they say the increase of alkali to 70 g. diminishe the reducing power of lactose about 1 p.o.

SWAR.

is also used (b) quantitatively, to determine the reducing power and the quantity of a sugar.

(a) Qualitatively. A portion of the solution supposed to contain sugar, prepared as described, is heated to boiling in a small beaker or test-tube, and is added to 5 c.c. of the alkaline copper solution previously diluted with its own bulk of water, and heated to boiling. The production of a red pp. of Cu₂O indicates the presence of a reducing sugar. There are substances besides the sugars capable of reducing Fehling's solution. The absence of these must be established before it can be inferred that the reduction is due to sugar.

(b) Quantitatively. The reducing power of a sugars, or of a solution containing reducing sugars, can be determined volumetrically or gravimetrically, with Fehling's solution. It is now very generally admitted that the gravimetric method gives the only reliable resulfs.

method gives the only reliable results.

Volumetrically. The sugar solution, prepared as described, should be diluted (0.5 to 1.0 g. reducing sugar in 100 c.c.). This is introduced into a burette, and the Fehling's solution into a second one. Of the latter a definite quantity, say 10 c.c., is measured into a porcelain dish of about 60 to 100 c.c. capacity, and diluted with four times its own bulk of water. The dish is then placed over a small Bunsen, and the contents heated to boiling. The sugar solution is then run in a c.c. at a time until the blue colour of the copper solution has nearly all disappeared, then drop by drop until it has quite gone. The first experiment may only give approximate results; in a second a quantity of sugar slightly less than was found necessary in the first experiment is measured into a small beaker, heated to boiling, and mixed rapidly with the boiling dilute copper solution. If the whole of the copper is reduced, a few drops more of the Fehling's solution are added from the burette. A few experiments of this kind will give fairly approximately the amount of copper solution a certain quantity of the sugar solution is capable of reducing. That the Fehling's solution is not in excess is seen by the absence of blue on subsidence of the Cu.O, and may be confirmed by filtering a little and testing for copper with a dilute solution of potassium ferrocyanide in acetic acid. The absence of a brown colouration indicates the absence of CuO. If the sugar is in excess, more CuO solution is decolourised, but after boiling the sugar in the alkaline solution the amount reduced is not a measure of the quantity of sugar. The final experiment must be performed after two or more observations, when the relative value of the two solutions has been approximately ascertained, as described above, by adding the whole, or nearly the whole, of the sugar at a boiling temperature to the copper solution at once. If only a few drops of the sugar solution are required to remove the last traces of CnO, the error is not great; 10 c.c. of the Fehling's solution, made as directed, contain ·1100 g. CuO; 396 CuO = 180 dextrose, i.e. 5 mols. CuO (79.2 + 5 = 396) are reduced by 1 mol. dex-180, then 396:110 = 180:050 grams dextrose = 10 c.c. Fehling's solution. Soxhlet (l.c.) states that the value of the CuO solution in dextrose varies with the way in which the experiment is performed; that 10 c.c. undiluted Fehling's solution are reduced by

0-04753 g. dextrose, while it takes 0-0494 to reduce the same bulk diluted with four measures of water. The same applies to the other reducing sugars, only in the case of lattose dilution has no effect, while in that of maltose dilution diminishes the amount of sugar required. This is, no doubt, correct under the conditions stated, but it is not necessary in dealing with a reaction of this kind to deviate from recognised conditions such as those laid down above. When these are adhered to it is found that the reducing power of the sugar very closely approaches molecular interaction; in fact, so much so that the molecular relation most closely approximated to by the experimental data may be taken as the normal reducing power of a sugar. These normals for the better-known sugars are:—

583

10 c.o. Fehling's solution = 0.0500 g. dextrose.*

" 0.0500 g. lectrose.

" 0.0500 g. lectrose.

" 0.06334 g. lactose.†

" 0.07196 g. maltose.†

" 0.04630 g. arabinose.

" 0.08701 g. arabinose.

Saxhlet says the reducing power of lawrolose is different from that of dextrose. This is not supported; his error is due to his mode of preparing invert sugar.

† Sugar free from water of crystallisation.

Gravimetrically. The Fehling's solution is prepared as described; 25-30 c.c. of it are measured into a beaker of 130-140 c.c. capacity, and about 50 c.c. well boiled water added. The beaker is then placed in a boiling-water bath, consisting of a larger beaker in which water is kept boiling. At the end of five or six minutes, when the dilute copper solution has acquired the temperature of the bath, a known weight or measure of the sugar solution is heated to boiling, and added. If at the end of a few minutes the blue colour is completely destroyed, it can be restored by adding more Fehling's solution, but it is much better to so arrange matters by a few experiments that the amount of sugar solution employed will reduce the Fehling's as nearly as possible, leaving only sufficient blue, on subsidence of the Cu₂O, to make it evident that the copper solution is in slight excess.

After twelve fourteen minutes' boiling the clear supernatant liquid is decanted on to a filter, the Cu₂O is washed by decantation, and finally on the filter. If the Febling's solution is in large excess it is difficult to wash the filter free from unreduced copper oxide (blue colouration), but if the excess is only slight there is no indication that the filter retains copper compounds other than Cu2O. Ignition for four or five minutes in , an open porcelain crucible converts the red precipitate into black copper oxide CuO, in which form it is weighed. From this the sugar is calculated by multiplying by the constants (see next page). It may be again pointed out that the factors given by various authorities differ more or less from these (see the K of individual sugars), but I believe these are the constants, the differences amongst the authors being due to manipulation, to the state of dilution and alkalinity of the solutions, and to the temperature of the mixed sugar and CuO solution. An imperfect knowledge of the composition of the material is a source of error. In dealing with some solutions, other

These should be ascertained, determined, and allowed for. In dealing with solutions in which ammonia is found, or liberated by the alkali, Cu₂O is retained in solution. Sundry propositions have been made to avoid the disturbing influence of the alkali in Fehling's solution, but they seem to have met with no favour. Sold ini (B. 9, 1126) proposed copper carbonate in potassium bicarbonate; Possoz (G. R. 1874, 721) and Pellet (J. fb. 19, 22) other solutions of copper in alkaline carbonates. Löwe (Fr. 9, 20) re-commends the use of a solution of CuO in glycerol, but so far little can be said of the value of the solution. In cases where the sugar solution contains other substances than reducing sugars capable of giving a precipitate with Fehling's solution without reduction, the whole precipitate may be dissolved in hydrochloric acid, made strongly alkaline, and added to an excess of ammoniacal solution of silver nitrate. The copper suboxide reduces an equivalent quantity of silver oxide. The silver in the precipitate may be estimated as chloride (Jean, C. R. 73, 1397). As has been stated above, many other solutions and modifications of Fehling's solution, have been proposed for employment in determining the sugars, but they appear to be of no value.

Pavy (i.e.) recommends the addition of sufficient ammonia to the Fehling's solution to hold the Ou,O in solution; the disappearance of the blue is then the indicator of the reaction. The reducing powers for sugars other than dextrose for this solution have not been ascertained; even for dextrose it is doubtful (v. Hehner, An. 6, 218).

Three solutions of mercury salts have been proposed as agents by which sugars can be determined by their reducing power—the one known as Knapp's solution, the other as Sachsse's solution, and the third as Hager's solution. Neither of them are of high value, except in certain circumstances, but Hager's least of all.

Knapp's solution is made by dissolving 10 g. HgCy, in about 600 c.c. water, then adding gradually 100 c.c. sodium hydroxide solution, specific gravity 1·145, and diluting the clear solution to 1 litre; 10 c.c. of this solution equal 0·025 g. dextrose; but according to Soxhlet (l.c.) this is not true, and the quantity varies with the conditions under which the reducing solution and reducible one are brought in determining the absence of mercury. The solution is used as follows:—40 c.c. of it are heated to boiling in a flask, and the sugar solution, which should not contain more than 0·5 p.c. reducing sugar calculated as dextrose, run in as quickly as possible until the whole of the mercury is ppd. as such, the mixed liquids being kept continually boiling. The complete presipitation of the Hg is ascertained by testing for

schekances may be precipitated with the Cu₂O. It with ammonium sulphide, or alkaline tin solutions about for. In dealing with solutions in which ammonia is found, or liberated by the alkali, cu₂O is retained in solution. Sundry propositions have been made to avoid the disturbing influence of the alkali in Fehling's solution, but they seem to have met with no favour. Sold and (B. 9, 126). According to the solution, 2020-202 g. dextrose. 126) proposed corporate in postssium.

reduce 100 c.c. of Knapp's solution. Sachse's solution is made to contain in 1 litre 18 g. mercuric iodide, 25 g. potassium iodide, and 80 g. potassium hydroxide. The mercury salt is dissolved in a solution of the potassium iodide, the solution of the potassium hydroxide added, and the mixture made up to the litre. A measured quantity, 40 c.c., of the solution is boiled in a porcelain dish, and the sugar solution, containing not more than 0.5 g. per 100 c.c., run in until a drop of the supernatant liquid ceases to give a brown colour with an alkaline solution of tin chloride. It is said that in using this reagent more mercury is reduced by adding the sugar slowly than by adding it all at one time, the reverse being the case with Knapp's solution. Soxhlet (l.c.) compares-the value of these solutions for the reducing sugars as follows:-

Taking the reducing power of dextrose = 100, the reducing powers (K) of the other sugars are:

•	Fehling (undiluted)	Knapp	Sachsse
Dextrose	100	100	100
Invert sugar .	96.2	99	124.5
Lævulose .	92.4	102·2	148.6
Galactose	. 93.2	. 83.0	74.8
Lactose (hydrated	?) 70·3	64.9	70·9
Maltose (dry?).	. 61.0	63.8	. 65.0

These relations for the K of the sugars for Fehling's solution do not agree at all with the generally recorded numbers (v. K of individual sugars); there are no data to enable one to form an opinion on the value of the K for the other solutions.

Potassium ferricyanide has been proposed as an agent for determining the reducing power of the sugars by Gentele (Er. 9, 453), but although Stahlschmidt (B. 1, 141), Stammer (D. P. J. 158, 40), and Sostmann (V. Z. 22, 170) have worked with it, we know nothing very definite about its value. It should yield definite results, as the complete reduction is definitely recognisable.

6. The action of unorganised ferments. Ensymes. Sucrose is converted by invertase into levulose and dextrose; the only other sugar acted upon by this enzyme is raffinose (Kjeldahl, Fr. 22, 588; O'Sullivan, C. J. 1896. 70; and O'Sullivan a. Tompson, C. J. 1890. 834), and, as it has been shown, the invertive action is most active at a temperature at which yeast, from which the invertase is prepared, has no fermentative action on the products of the inversion; yeast can be employed instead of prepared invertase. The products of the action of invertase

on rainness are sevulose and meliblose, the latter yielding finally dextrose and galactose. Raffinose is but very sparely distributed. It may be considered that sucrose is present if the optical activity of a solution is materially altered by treatment with invertase and the copper oxide reducing power at the same time increased. The absence of raffinose can be determined by the non-production of mucic acid on treatment with nitric acid. Before applying the invertase test the solution to be tested must be boiled. If this is not done, and active diastase and any of the high-starch transformation products are present, the latter would be acted upon by the diastase, the opticity lowered, and the cupric reducing power increased. "Diastase does not appear to act on any of the sugars, except isomaltose (?)

Other organisms, such as the moulds which grow on steamed rice, contain an enzyme capable of acting on maltose, but this substance has not been employed in the detection or estimation of maltose. There is no doubt, however,

mation of maltose. There is no it is available for the purpose.

7. Organised Ferments (see Fermentation). The hyphomycetes, saccharomycetes, and schizomycetenact on the sugars and yield various products, and, no doubt, can be made available for the detection and estimation of them; but we have only to concern ourselves here with the action of ordinary beer yeast (saccharomyces cerevisiæ); the changes effected by the other organisms come under art. Fermentation. On adding pressed yeast to a very slightly acid solution, and keeping the mixture at a temperature of 20° or thereabouts, if a fermentable sugar be present, a frothy head will form on the surface of the liquid, carbon dioxide will be evolved, and alcohol formed. The specific gravity and optical activity of the solution diminishes. Certain substances known as antiseptics prevent this reaction—they must be proved to be absent. The fermentable sugars, in this sense, are described as such under the respective heads.

The quantitative value of this phenomenon has been studied by many workers, but it is still unsatisfactory. It has been made available with approximate accuracy in determining the total fermentable sugars in presence of other substances from which they cannot otherwise be conveniently separated. The solution should be conveniently separated. The solution should be of about sp.gr. 1.050-1.060, slightly acid, and should not contain much foreign matter. A measured quantity of this is taken, best 100 c.c. if available, introduced into a 150 c.c. flask, and 0.5 to 1 g. freshly-pressed yeast added. If necessary, a little yeast ash dissolved in the least possible quantity of hydrochloric acid, together with a little ammonium tartrate, should be added. A temperature of from 20° to 22° is best suited for the process. The gas evolved is washed by being made to pass through a few c.c. water in two successive wash-bottles. In some cases the fermentation is very slow and takes many days to complete itself, in others it is rapid and is finished in a few days; but in all cases it should be continued as long as gas bubbles through the wash-bottles on shaking the flask in which the fermentation is going on. As soon as this point is arrived at, the contents of the flask are washed with the water of the wash-bottles into a distilling flask, and submitted to distillation. Dilute alco-

hol distils over and is collected in a 100 c.c. flask. If only 20-25 c.c. washerater were used, the distillate, when it amounts to 80-85 c.c., will contain all the alcohol produced. This is then made up to 100 c.c. and its specific gravity taken. On referring to the alcohol tables, the weight of alcohol in the 100 c.c. is ascertained. From this a knowledge of the amount of fermentable sugars is arrived at. Sucrose yields 51 p.c. alcohol, dextrose 48-49 p.c. (Pasteur, A. Ch. [3] 58, 330), maltose 50.4-51.8 p.c. (O'Sullivan, C. J 1876, 479). Hofmann, Graham, and Redwood (C. J. 5, 229) gave expression to the value of the specific gravity of distillate, in points or degrees of specific gravity lost by the saccharine solution fermented for various sugars. These factors are still employed in determining the original specific gravity of beer, from the alcohol it contains and the specific gravity of the residue after distillation. The residue left in the distilling flask mentioned above is with the washings made up to 100 c.c., the specific gravity of this solution subtracted from that of the solution before the yeast was added + 1-or 1000 if water be taken at 1000 instead of 1—will give approximately the specific gravity of a solution containing the amount of sugars or sugar fermented in 100 c.c. The average D of the sugars being known, the quantity fermented within 2 or 3 p.c. can be calculated from this. Inasmuch, however, as the value in specific gravity of the non-volatile products of the fermentation of the sugars has not been accurately determined, this mode of estimation can only be approximate.

It has been proposed to estimate the amount of sugar or sugars by determining the amount of carbon dioxide evolved during fermentation. Pasteur (L.) 'gives 0.4665 g. CO, as the product of 1 g. demose. Jodlbauer (Z. V. 25, 308) states that dry maltose yields 49.54 p.c. CO, and dextrose 46.54 p.c. These figures are, no doubt, true also for all the fermentable '-on' and '-ose'

sugars.

Some of the sugars when in the pure state are not fermented by yeast, but the presence of as small quantity of an easily fermentable sugar sets up the action. Pure galactose is not fer-mented by yeast; the presence of a little dex-trose, layulose, or maltose sets up the process (Bourquelot, C. R. 106, 283; Tollensa, Stone, B. 21, 1572; Stone a. Tollens, A. 249, 257), the fermentation of galactose being as complete as that of dextrose if the suitable nourishment is present. Under the same condition sorbose ferments more slowly and less completely, arabinose and lactose very slowly and incompletely.

Pure arabinose behaves like pure galactose. Sucrose is inverted by yeast, dextrose ferments easily, lævulose less so, maltose still less, and raffinose less still. The other sugars ferment only when these are present; hence it should be possible to detect the presence of individual sugars from the specific rotatory power and K by fractional fermentation. With some varieties of yeast lavulose ferments before dextrose (Dubourg, yeast tevening the 'ose' sugars and to be incapable of fermenting the 'on' ones. A study A study of the action of these organisms will yield results. valuable in the identification and estimation of the sugars.

8. Action of acids. All the di- and tri- sugars are converted in mono- sugars by the action of dilute mineral acids; this is accompanied by an alteration in the K and [a] of the solution. If this took place only with the high sugars, the reaction would be applicable in distinguishing the '-on ' and '-ose -on' sugars from the '-ose; but the K and [a] of these sugars are also affected by digestion with mineral acids, but much more slowly, so that the reaction is only available when carefully performed. If the sugar solution increase in K, and there is a material alteration in [a] on ten or twelve minutes' boiling with 2-3 p.c. sulphuric acid or hydrochloric acid. it may safely be inferred that a high sugar di- or tri-) is present. Some organic acids act differently on the high sugars. Dilute citric acid inverts sucrose; it is without action, at least material action, in a short time on lactose (Jones, l.c.). .

The invertive action of acids—except under well-defined conditions, such as the employment of hydrochloric acid by Clerget in hydrolysing sucrose—cannot, for the reason mentioned above, be employed in estimating these sugars.

Dextrose and substances capable of yielding it can be detected by acting on the material with nitric acid (1 pt. mat. 1 pt. H.O and 5 pts. nitric acid, sp.gr. 1·15). Saccharic acid, recognisable by the microscopic appearance of its acid potassium salt, is produced (Sohst a. Tollens, A. 245,1). Lævulose, galactose, sorbose, and arabinose do not yield this acid (Gans, Stone, a. Tollens, B. 21, 2148). Galactose, lactose, and raffinose, on treatment with nitric gold in the same way, yield mucic acid. This reaction has some quantitative value. Pasteur (C. R. 42, 349) obtained 75 to 78 p.c. mucic acid from galactose. The yield, however, varies very considerably with the quantity and strength of the acid employed. Kent a. Tollens (A. 227, 221) find on employing 1 pt. sugar, 12 pts. nitric acid, sp.gr. 1·15, allowing to crystallise in 1·5 to 2·0 pts. solution, and washing with 5 pts. water that galactose gives 77.4 p.c. mucic acid. Lactose treated in the same way gives 40 p.c., and raffinose (Rischbieth a. Tollens, A. 232, 172) 22-23 p.c. By using 1 g. dry sugar, or a quantity equal thereto, in a concentrated syrup, 4 g. nitric acid sp.gr. 1.25-1.24, heating gently until red fumes began to be evolved, then allowing the reaction to proceed until the violence was over, heating on a water-bath until red fumes ceased to be evolved. allowing to stand for 24 hours to crystallise, I obtained 73 p.c. mucic acid from galactose, 36.9 p.c. from dry lactose, and 28-30 p.c. from dry raffinose (O'Sullivan, C. J. 1886, 73). The mucie acid was collected on a tared filter, washed carefully with 50 c.c. water, dried in a vacuum over sulphuric acid, then at 100°, and weighed. By treating 0.5 g. mucic acid in the same way, the loss was 0.04-0.05 g. Corrected for this the above numbers become 80-81 p.c. for galactose and 40.5-41.5 p.c. for lactose. The number for raffinose was corrected.

The pentoses, and bodies from which they can be obtained, yield on digestion with strong hydrochloric acid, furfural, the detection of which is simple and definite. This reaction has been employed in the estimation of these sugars. It must not, however, be forgotten that the hexoses also yield furfural, although, no doubt, in very small

quantities (Günther a. Tollens, B. 23, 1751; de Chalmot a. Tollens, B. 24, 694; Stone, B. 24, 3019). The first difficulty to overcome was to determine the conditions under which the greatest yield of furfural was obtainable, the next to accurately determine the furfural. 2 to 5 g. of the material are digested with 100 c.c. hydrochloric acid, sp.gr. 1.06, and then distilling, returning the distillate until the reaction is complete; or the mixture of material and acid is submitted to distillation in a flask over a small flame, so that not more than 10 c.c. distillate pass over in five minutes, fresh acid being regularly added until a sample of the distillate ceases to give the reaction for furfural. The distillate is then neutralised with soda, acidified with a few drops of acetic acid, and made up to a definite volume. In this the furfural is estimated by a standard solution of phenylhydrazine, made by dissolving 2 g. phenylhydrazine chloride with 6 g. sodium acetate in 1 litre water. This is standardised with a solution of furfural of known strength (1 g. pure furfuramide in a little acetic acid to 1 ltr. water). Standardisation must be made before each set of determinations, as the phenylhydrazine solution loses its valm in a short time. The titration is performed as follows: 25 c.c. of the distillate are mixed with a measured quantity of the phenylhydrazine solution, the mixture rapidly boiled and cooled; a little of the solution is filtered and boiled with twice its volume of Fehling's solution; if the phonylhydrazine is in excess reduction takes place, but if furfural is in excess there is no reduction. Trials are made until the equivalent amount of phonylhydrazine solution is found (Stone, *l.c.*). The dilute acidified solution is precipitated with phenylhydrazine acetate, the hydrazide collected on an asbestos filter and dried in a vacuum in a specially-constructed apparatus at 50°-60° until the weight becomes constant. The precipitation is always effected in the same volume of solution, so that allow-ance can be made for the solubility of the hydrazide. Arabinose yields on an average 48.72 p.c. and zylose 56.25 p.c. furfural (de Chalmot-a. Tollens).

9. The action of alkalis. This can only be applied as a rough qualitative test. All the hexoses yield a brown colouration when boiled for a few minutes with a 3-4 p.c. solution sodium hydroxide. The '-on' sugars are not affected.

10. The action of phenylhydrazine. The melting-point of the osazones and hydrazides and composition thereof give good indication of the nature of the sugar whence they are prepared. For preparation and melting-point see individual sugars. Maquenne (C. R. 112, 799) finds that different sugars yield, with excess of phenylhydrazine, very different quantities of osazones. By heating 1 g, each sugar for one hour at 100° with 100 c.c. water, and 5 c.c. of a solution of phenylhydrazine acetate, containing in 1 litre 400 g. phenylhydrazine and 400 g. glacial acetic acid, cooling, collecting the precipitate, washing with 100 c.c. water and drying at 110°, he found sorbose gave 0.82 g., lævulose 0.70, xylose 0.40, dry dextrose 0.32, arabinose 0.27, galactose 0.23, rhamnose 0.15, lactose 0.11, maltose 0.11. There must, however, be some error or misunderstanding here, as there is nowifficulty in getting 120 o. o. osazone from arabinose and more than 180 p.c. from lavulose. C. O'S.

SULPHACETIC ACID v. SULPHOAGETIC ACID. SULPHAMIC ACID and SULPHAMATES SULPHAMIC ACID and SULPHAMATES SO. NH. OH and SO. NH. OM! (Amidosulphonic acid and Amidosulphonates.) By passing dry NH, over SO., Rose (P. 33, 81; 47, 471; 49, 189) obtained a compound SO. 2NH. This compound, called by Rose 'sulphatammon,' is generally described as ammonium sulphamate SO. NH. ONH, but Divers a. Haga (C. J. 61, 948) have shown, fairly conclusively, that the compound is tri-ammonium imidosulphonate (N(NH.)(SO. ONH.), [2 = SSO. 4NH.]; this salt is described under Imidosulphonic acid and its salts (v. Sulphonic acid and its salts (v. Sulphonic acids and Derivatives, p. 600).

Barium sulphamate SO_xNH_xO Sa seems to have been obtained by Berglund (B. 9, 1896) by boiling an aqueous solution of barium imidosulphonate HN SO_xO Ba (v. Imidosulphonic acid under SULPHONIC ACIDS AND DERIVATIVES, p. 600) till the solution reacted strongly acid, adding excess BaOAq, boiling so long as NH_x came off, filtering, removing excess of Ba by passing in CO_x, filtering, evaporating the filtrate to a small bulk, and allowing to stand. The salt crystallises in long, lustrous needles; it is not changed by heating to 200°, nor by boiling in solution, even in presence of HClAq.

Berglund (i.c.) says that a solution of potassium sulphamate is obtained by the reaction of nascent hydrogen with potassium oxyamidosulphonic acid under Sulphonic acid under NHOH.SO.OKAq + 2H = NH...SO.OKAq + H.O. B. was unable to isolate the salt. Raschig (A. 241, 176) obtained the potassium imidosulphonate NH(SO.OK), with a little water for some time, removing the H₂SO, that was produced by CaCO, filtering from CaSO,, evaporating, pouring off from K₂SO, that separated, and allowing the syrupy mother-liquor to crystallise. The salt separated in large colourless, rhombic crystals. In 1878 Berglund prepared several sulphamates, viz. the salts of NH, Cd, Ca, Co, Cu, Pb, Li, Mn, Ni, Ag, Na, Sr, Tl, and Zn (Lunds Universitets Arsskrift, 13; abstract in Bl. [2] 29, 422).

SULPHAMO ACD SO, NH, OH. This acid was obtained by Berglund (Lc.) by passing H,S into a solution of the silver salt, filtering from Ag,S, and evaporating over H,SO,. It forms large, transluceat, rhombic crystals; the ratio a:b:c = '9945:1:1056 (Raschig, A. 241, 178). Easily sol. water, less sol. alcohol; aqueous solution only slowly decomposed to NH, H.SO, on boiling; more rapidly decomposed if HClAq is added; not decomposed by heating to 190° (B., Lc.). A solution of the acid gives no pp. with BaOAq; on boiling with HClAq and BaCl,Aq a pp. of BaSO, gradually forms. Raschig (Lc. p. 209) obtained sulphamic acid by saturating a solution of hydroxylamine hydrochloride with SO, allowing to stand for a little, and then evaporating on a water-bath (NH,OH,HClAq + H.SO,OHAq = NH.SO,OHAq + HClAq + H.SO,OHAq

= NH, SO, OHAq + HOlAq + H₂O).

SULPHAMIDE SO (NH₂); (Sulphonamide.

Sulphurylamide.) The neutral amide of sul-

phuric acid is obtained by passing dry NH, into cooled SO, Cl., diluted with 15 to 20 vols. CHCl., to complete saturation, dissolving the pp. so produced in water, making strongly acid by HNO, Aq, ppg. Cl as AgCl by addition of AgNO, Aq, filtering, neutralising by KOHAq, and again ppg. by AgNO, Aq, filtering from SO, NAg (v. Sulphimos, p. 587), adding more AgNO, Aq and then KOHAq, warming and then cooling quickly, and collecting the pp. that forms. This pp. consists chiefly of SO, (NHAg), but there is a small quantity of another Ag salt which must be removed. This is done by washing well, adding exactly enough HClAq to convert all Ag into AgCl, neutralising by NH, Aq, adding AgNO, Aq, filtering from the pp. of the foreign Ag salt, adding more AgNO, Aq and then excess of NH, Aq, when pure SO, (NHAg), is ppd. The salt is decomposed by exactly the proper quantity of HClAq, AgCl is filtered off, the filtrate is evaporated in vacuo at a temperature not above 40°, and the liquid is allowed to remain invacuo over H, SO, when SO, (NHA,), separates in large, colourless crystals (W. Traube, B. 26, 607). Sulphamide is very sol. water, less sol. dilute alcohol, insol. alcohol, ether, and other ordinary organic solvents; it softens at 75° and melts at 81°, begins to give off NH, below 100°, no further decomposition occurring to 250°; above 250° gives off acid vapours, and is completely decomposed. An aqueous solution of sulphamide is neutral; boiled with acids it gives H, SO, Aq and NH₃. Solutions of alkalis split off NH₃ and form alkali salts of SO, OHNH₂. Small quantities of H, SO, Aq are formed after prolonged boiling. By adding AgNO, Aq to solutions of sulphamide, and then NH₃Aq, a pp. of SO₂(NHAg), is formed; other metallic derivativos of SO₂(NHA₂), exist, but have not yet been isolated gatisfactorily.

IMIDO-SULPHAMIDE NH(SO₂.NH₂)₂ v. SULPRIMIDO-AMIDE (p. 587). M. M. P. M. SULPHAMINE-BENZOIC ACID v. Amide of

SULPHONIC ACIDS AND DERRANTES, P. 800.

SULPHATES and allied salts. Salts of sulphuric acid H₂SO₂. The compositions of the normal sulphates are expressed by the general formules M₂SO₂, M¹¹SO₂, M¹¹SO₃, and M¹¹(SO₄)₂; the greater number of the acid sulphates come under such formules as M¹HSO₄. M¹¹H(SO₄)₂, M¹¹H(SO₄)₃. All sulphates, whether normal, acid, or basic, may be represented by the formula nMO.mSO₃. LHO, where MO stands for a basic oxide. The sulphates are prepared (1) by the interaction of H₂SO₄Aq with metals, metallic oxides, or hydroxides; some metals react with dilute H₂SO₄Aq, giving sulphates and H₂ others react only with

SO, and H.S., and sometimes H also; (2) by the interaction of H.SO, Aq with salts of volatilisable or decomposable scids, e.g. with chlorides, nitrates, or carbonates; (3) by the direct combina-tion of SO₃ with metallic oxides; (4) by oxidising sulphides, by boiling with HNO, Aq, or by reacting with Cl in presence of water, or sometimes by with UI in presence of water, or sometimes by heating in air, e.g. FeSO, CuSO, and ZnSO,; (5) by double decomposition from other sulphates, e.g. BaSO, PbSO. Most of the metallic normal sulphates are soluble in water; BaSO, is insol. water, PbSO, and SrSO, nearly insol., and CaSO, very slightly soluble. The basic sulphates are generally insoluble in water. Sulphates of metals whose oxides are strong bases-the alkali and alkaline earth metals -are not decomposed by heat alone; the sulphates of metals whose oxides are weak bases are decomposed by heating, giving off SO,, or SO, and O, and leaving oxides, or metals if the oxides are reducible by heat. Sulphates are reduced by heating with charcoal, either to sulphides or oxides, with evolution of CO and CO, and also SO, from the sulphates of weak bases. Many sulphates are decomposed completely by heating with HCl gas, giving chlorides (v. Hensgen, B. 9, 1671; 10, 259). Fusion with excess of alkali carbonate produces alkali sulphate and carbonate of the metal of the original sulphate. Many sulphates are reduced by strongly heating in a stream of NH₂, yielding sulphides, oxides, metal, or mixtures of these (v. Hodgkinson a. Trench, C. N. 66, 223). Several sulphates occur as minerals; e.g. BaSO, (heavy spar), CaSO, (gyp-

sum), SrSO, (celestine), MgSO, (Epsom salts), &c. Aluminium sulphates. The normal salt Al₄(SO₄), 18aq occurs native as feather alum; it is prepared by heating clay with conc. H₂SO, Aq and boiling down the solution; also, ascording to Persoz (A. Ch. [8] 56, 102), by adding solution of alum or AlCl, to a large excess of conc. boiling H₂SO₄, when anhydrous Al₄(SO₄), separates as a white powder. Gawalovski (C. C. 1885, 721) says that perfect octahedral crystals of Al₄(SO₄), 17aq are obtained by saturating H₂SO₄Aq with freshly ppd. AlO, H₂ and allowing to stand for some months. Crystallises with difficulty from water; crystallisation hastened by adding alcohol in which the salt is insol. (P., Le.). Concerning ppn. of Al₄(SO₄), xH₄O from aqueous solutions by H₂SO₄ v. Eremin, J. R. 20, 468 (abstract in C. J. 56, 347). When heated gives off all water; heated to redness gives off SO₄ and leaves AlO₂. Various basic salts are known; they are obtained by heating rolution of Al₂(SO₄), with AlO₂H₄, or by partially ppg. solution of the normal salt, by NH₄Aq, or by partial reduction of the normal salt, by NH₄Aq, or by partial reduction of the normal salt, by NH₄Aq, or by Partially condition of the normal salt, by NH₄Aq, or by Partially condition of the normal salt, by NH₄Aq, or by Partially ppg. solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solution of the normal salt, by NH₄Aq, or by Partially ppg. Solutio

89, 9).
The double salts Al₂(SO₁), M₂SO₁, 24aq, where
M=NH, Na, K, Rb, Ca, Ag, or Tl, are alums.
For expansions of alums v. Spring, B. 15, 1254,
1739; 17, 408.

Ammonia alum Al.(SO,), (NH,) SO, 24aq, prepared by adding (NH,) SO, or NH,Cl to Al.(SO,), Aq, so that the salts are in equivalent quantities, crystallises in octahedra; S.G. 1.56;

sone. H.SU., giving sulphates and SO. on S. 5-22 a. p., wary at 100°. Heated to 190°. SO, and H.S. and sometimes H also; (2) by the 2H.O is given off and Al.(SO.). (NH.). SO, and interaction of H.SO.Aq with salts of volatilisable or decomposable acids, e.g. with chlorides, ni- (Lupton, C. J. [2] 13, 201).

Potash alum Al₂(SO₄), K.SO₄. 24aq, prepared by mixing solutions of the two sulphates and evaporating, crystallises in regular cotahedra; S.G. 1.7; S. 3.29 at 0°, 9.52 at 10°, 22 at 30°, 31 at 60°, 90 at 70°, 357 at 100°. The crystals effloresce in air. At 190°, 23H₂O is given off (L., *l.c.*). Also obtained in cubical crystals (v. Polis, B. 18, 360). Solution in water has an acid reaction, and dissolves Zn and Fe, giving off H.

Cæsium and rubidium alums v. Bunsen, P. 119, 1; Godeffroy, B. 181, 176; Redtenbacher, J. pr. 95, 148. Setterberg (A. 211, 100) gives S. in water from 0° to 80° (cf. Cæsium,

vol. i. p. 658).
Silver alum v. Church a. Northcote, C. N.
9, 155.

Sodium alum v. Pouisin, Polytech. Centralbl. 1852, 774; Zellner, S. 36, 183; and especially Augé, C. R. 110, 1139 (abstract in C. J. 58, 1059).

cially Augé, C. R. 110, 1105 (austral) 258, 1059).

The allium alum v. Lamy, Bl: [2] 11, 210.

The double salts of $Al_2(SO_4)$, with FeSO, MgSO, MnSO, and ZnSO, also crystallise with 24H,0.

For double salts with $Fe_1(SO_4)$, $Mn_2(SO_4)$, and $Cr_2(SO_4)$, v. Etard (Bl. [2] 31, 200). For a double salt with PbSO, v. Bailey (C. S. L. 6, 415).

Salt with PbSO, v. Bailey (C. S. I. 6, 415).

Ammonium sulphates. The normal salt (NH₄)₂SO₄ is found in certain volcanic districts; it is prepared by neutralising H₂SO₄Aq by NH₂Aq or (NH₄)₂OO₄Aq and evaporating. Crystallies in clear rhombic forms, is isomorphous with K₂SO₄ (Mitscherlich, P. 18, 168). S.G. 1761 (Playfair a. Joule, C. S. Mem. 2, 401); for S.G. from 10° to 100° v. Spring (B. 15, 1940). Melts at c. 140° (Marchand, P. 42); decomposes above 280°; according to Johnson a. Chittenden (Am. S. [3] 15, 131), gives NH₄HSO₄ and (NH₄)₂S₂O₅, and at incipient redness gives SO₅, H₂O, and NH₄. Absorbs dry HCl, forming some NH₄Cl (v. Thomas, C. J. 33, 372). S. 71 at 0°, 73·65 at 10°, 76·3 at 20°, 78·95 at 30°, 81·6 at 40°, 84·25 at 50°, 86·9 at 60°, 89·55 at 70°, 92·2 at 80°, 94·85 at 90°, 97·5 at 100° (Alluard, C. R. 59, 500). Insol. absolute alcohol. For S.G. of (NH₄)₂SO₄Aq from 1 to 50 p.c. (NH₂)₃SO₄ v. Schiff (A. 108, 338; 110, 74). H.F. (N'₄H*₂S,O'₁ = 284,800 (Thomsen, J. pr. 21, 477). The acid salt NH₄HSO₄ crystallises from solution of (NH₄)₂SO₄ in hot conc. H₅O₄ (NH₂)₄C(So₄H₄O) by adding the proper quantity of H₂SO₄ (NH₄)₂SO₄Aq (Marignac, Ann. M. [5] 12, 89; (2) (NH₄)₂SO₄Q₄ (Marignac, Ann. M. 6) the color of the

Antimony sulphates. The normal salt Sb₂(SO₄), is obtained by dissolving Sb₂O₂ in boiling conc. H₂SO₄ (c. 98 p.c. H₂SO₄), resulting from conc. H₂SO₄, and drying on a porous tile over H₂SO₄. (Adie, C. J. 57, 540; where an account of the action of H₂SO₄ of different concentrations, and of SO₄, on Sb₂O₃, will be found, with references to older papers).

Barium sulphates. The normal salt BaSO, ! occurs native as heavy spar. Prepared by adding dilute H.SO.Aq or dilute solution of a suling dilute H.SO.Aq or dilute solution of a sulphate to solution of a salt of Ba, washing, and drying. A white solid; S.G. 4:525 (G. Rose, P. 75, 409; v. also Schröder, P. 106, 226; a. Wiedemann; P. M. [5] 15, 371). Obtained as a crystalline powder by fusing 1 part K.SO, with 4½ parts dry BaCl, in a closed crucible, and washing with water (Manross, A. 82, 348); also by heating dilute BaCl, Aq with slight excess of H.SO.Aq to 245° (Scheerer a. Drechsel, J. pr. [2] 7, 63). H.F. [Ba,O',S] = c. 338,000 (Th. 3, 516). Insol. water; 1 part dissolves in c. 23,000 parts cold, and in c. 4,900 parts hOt, HClAq S.G. 1-33, and in c. 9,200 parts hNO.Aq S.G. S.G. 1.03, and in c. 9,200 parts HNO, Aq S.G. 102. Struve (Fr. 9, 34) gives S. of BaSO, in conc. H₂SO, as 5·69, and 15·89 in Nordhausen acid. BaSO, is partly decomposed by boiling with conc. solution of an alkali carbonate, or by fusion with alkali carbonate; Spring (Bl. [2]44, 166) found that some BaCO, was formed by compressing BaSO, and Na₂CO, at a pressure of c. 6,000 atmospheres.

An acid salt BaSO₄.H₂SO₄ is formed by dissolving BaSO₄ in hot cone. H₂SO₄ S.G. 1.843, and heating to 100° (v. Garside, C. N. 31, 245).

Beryllium sulphates. The normal salt Deso taq is formed by dissolving BeCO, in dilute 1.SO, Aq and concentrating the slightly For crystalline form v. Topsöe acid liquid. W. A. B. 66 [2nd part], 5). According to Klatzo (J. pr. 106, 233) the salt crystallises with 7H,O. Various basic salts are obtained by the action of BeCO_s or Zn on solution of the normal salt.

Bismuth sulphates. The normal salt

Bi₂(SO₄)₃ is best prepared by dissolving Bi₂S₂ in conc. H₂SO₄ heated to commencing vaporisation; on cooling the salt separates in lustrous, very deliquescent, needles (Hensgen, R. T. C. 4, 401; tendrescent, needes (Hensgen, H. 1. C. 2, 61, cf. Schultz-Sellack, B. 4, 13). For the action of heat on Bi₂(SO₄), v. Bailey (C. J. 51, 680). An acid salt BiH(SO₄), 3aq was obtained by Leist (A. 160, 29) by dissolving Bi₂O₄ in dil. H₂SO₄Aq under definite conditions. Basic salts are also formed by the reaction of dilute H2SO, Aq with Bi₂O₂ (v. Heintz, P. 63, 55, 567), and by the action of H₂O on the normal salt (cf. Hensgen,

According to R. H. Adie (priv. comm.), acid salts BiH(SO₄)₂, xaq (x = probably 1 and 3) crystallise from solutions of Bi₂O₅ or Bi₂(SO₄)₃ in H.SO, Aq of concentrations varying from H.SO, H.O to c. H.SO, 5H.O; from soid of the concentration H.SO, 6H.O, a basic salt crystallises, probably Bi.OH.SO, H.O.

Cadmium sulphates. The normal salt

camnum suppates. The normal salt CdSO₄, aq is obtained by dissolving Cd in dilute H₂SO₄Aq, and concentrating, by boiling, the acid solution (von Hauer, J. pr. 72, 372). Various other hydrates have been isolated. H.F. [Cd,S,O'] = 221,550 (Th. 8, 516). CdSO₄ combines with NH, to form various compounds (v. H. Rose, P. 20, 152; Malagutia. Sarzeau, A.Oh. 181 0, 481; Isambert. C. R. 70. 456: Müller. A. [8] 0, 481; Isambert, C. R. 70, 456; Müller, A. 149, 70). Forms double salts with (NH.), SO, MgSO, and Na,SO,; these salts crystallise with Gaq (von H., l.c.) The double salt with Al₂(SO₂), is an alum.

Cosium sulphates. Normal valt Cs₂SO₄; by neutralising H₂SO₄Aq by Cs₂CO₂ and evapo-

rating. Short needles, not hygroscopic; insol. alsohol 38. 158.7 at -2°. The acra sum constant formed by reacting on Cs,80, with excess of small rhombic prisms

(Bunsen a. Kirchoff, P. 113, 342).
Calcium sulphates. The normal salt CaSO. occurs native as anhydrite, and the dihydrate CaSO, 2aq as gypsum, alabaster, and selenite. CaSO, is obtained in crystals by fusing KaSO. with excess of CaCl, and washing (Manross, A. 82, 348; cf. Mitscherlich, P. 21, 321). CaSO, 2aq is formed by ppg. fairly conc. CaCl,Aq by dil. H2SO, Aq or solution of a sulphate, evaporating, and washing the solid that separates. CaSO, 2aq is said to be formed by the interaction of CaCO, and S moistened with water (Polacci, G. 1874. and S moistened with water (Polacci, G. 1874. 177, 245). CaSO, has S.G. 2·964, and CaSO, 2aq has S.G. 2·31 (v. also McCaleb, Am. 11, 35). S. for CaSO, '19 at 0°, '206 10°, '214 at 40°, '208 at 60°, '195 at 80°, '174 at 100° (Marignac, A. Ch. [5] 1, 274); S. for CaSO, 2aq '2119 at 16·5°, '2352 at 22° (Cossa, G. 1873. 135); S. for CaSO, 2aq in glycerin, '957 at ordinary temperature, S. increases at temperature rises (Asselin G. R. 76 creases as temperature rises (Asselin, C. R. 76, 884). According to Raupenstauch (C. C. 1888. 821) the solubility in water of gypoum increases to 32°, is constant from 32° to 38°, and decreases above 38°. Gypsum loses 2H,O when heated to 80° in a stream of dry air; when the CaSO. thus produced is moistened it takes up 2H.O. becomes crystalline, and expands. The dehydrated CaSO, obtained by heating gypsum to 160° takes up water very slowly; if the gyps is heated to c. 300° the CaSO, formed combines with water with extreme slowness (v. Schott, D. P. J. 202, 52, 355, 513; cf. Plaster of Paris, under CEMENTS, in DICTIONARY OF APPLIED CHEMISTRY, vol. i. p. 468).

According to Potilitzin (J. R. 1893 [1] 201, 207) CaSO₄. 2aq slowly gives off water at 62°-65° till the hydrate 2CaSO₄. aq is formed; CaSO₄ prepared by heating CaSO₄. 2aq to 180°-170° absorbs H₂O from ordinary air until 2CaSO₄. aq is formed when absorption of water ceases. The hydrate 2CaSO, aq absorbs water from air saturated with moisture, forming CaSO. 2aq. The water d crystallisation of gypsum is not equally firmly retained; P. writes the formula

equally firmly retained; P. writes the torindus 2CaSO₄. 4aq; three-quarters of the H₂O is much more readily given off than the other fough. The hydrate 2CaSO₂. aq is more soluble in water than the dihydrate CaSO₄. 2aq.

An acid salt CaH₂(SO₄), is said by Berzelius to be formed by digesting CaSO₄ with H₂SO₄Aq at 80°-100° † it is decomposed by moist air to the premal selt and HSO. For double salts with alkali and alkaline earth sulphates v. Fass-bender (B. 9, 1356; 11, 1968); Struve (Bl. [2] 12, 348); Ditte (C. R. 84, 86); Popp (A. Suppl. 8, 1); Hannay (C. J. 32, 399).

Cerium sulphates, The normal cerous sulphate, Ce₂(SO₄), xH₂O (x being probably 6, 8, 9, and 12) is obtained in colourless crystals by and 12) is obtained in colourless crystals by evaporating a solution of Ce₂(CO₂), in dilute H₂SO₄Aq, or a solution of CeO₂ in H₂SO₄Aq saturated with SO₂. The normal ceric salt Ce(SO₂), 4aq forms, in yellow crystals, from a solution of CeO₂ in dilute H₂SO₄Aq. Cerosceric sulphates, xCe₂(SO₂), yCe(SO₂), 2aq, are obtained by dissolving CeO₂ in cone. H₂SO₄ and exponenting Resis salts as formed by the evaporating. Basic salts are fermed by the

interaction of water with the normal salts. Double salts of $Ce_s(SO_s)$, with $(NH_s)_2SO_s$, K_sSO_s , and Na_sSO_s are known (v. Marignac, A. Ch. [4] 80, 57; Czudnowicz, J. pr. 30, 19; Hermann, J. pr. 92, 126; Zschiesche, J. pr. 107, 65; Rammelsberg, B. 6, 85; Jolin, BL. [2] 21, 523; Wyrouboff, BL. [3] 2, 745; Wing, Am. S. [2] 40, a_sch

Chromium sulphates. The normal chromous salt CrSO. 7aq was obtained by Moissan (BL. [2] 37, 296) by dissolving the acetate in warm dilute H.SO.Aq. crystallising, and drying between paper, all operations being conducted in an atmosphere of CO₂ (for directions for making Cr(C.H.O.), v. NITROGEN, Preparation, vol. iii. p. 557). Blue crystals; isomorphous with FeSO, 7aq. S. 12:35 at 0°; sl. sol. alcohol. Abreducer. A monohydra rSO, aq was obtained as a white crystalline powder by adding the acetate to excess of conc. H.SO, (M., l.c.). Forms a double salt, CrSO, K, SO, 6aq (Péligot, A. Ch.

[8] 12, 539).

The normal chromic salt Cr₂(SO₂), xH₂O exists in two forms. (1) Violet, x=15 (Schrötter, P. 53, 5.6),=18 (Siewert, A. 126, 97); by digesting 1 pt. CrO₂H₂ dried at 100° with 1 to 11 pts. conc. H₂SO₂, in a closed vessel, till a mass of greenish-blue crystals is formed, dissolving these crystals in water, ppg. by absolute alcohol, dissolving again in water, adding alcohol till ppn. just begins, covering the vessel with moist parchment paper, and allowing to crystallise parchment paper, and allowing to crystallise slowly. Regular octahedra; red-violet in reflected light, garnet-red in transmitted light; S. 120 in cold water (Schrötter, P. 53, 516; Löwel, A. Ch. [3] 40, 42). (2) Green, x=5. By heating the violet salt to 100°; the salt melts, gives off water, and then solidifies to a green amorphous mass. Also formed by dissolving CrO₂H, in cone. H₂SO₄ at 50°260°, and evaporating quickly. Easily sol. alcohol; whereas porating quickly. Easily sol. alcohol; whereas the violet salt is insol. alcohol.

Addition of a cold solution of a Ba salt ppts. all SO, from a solution of the violet form, but boiling is needed to complete the ppn. from the green variety. According to Et d (C. R. 84, 1089), the difference between the two forms is one of hydration only (but v. Chromium salts, vol.

ii.p. 167; and v. also Recoura, C. R. 113, 857). Basic salts are obtained by adding a little NH,Aq to solution of the normal salt, also by digesting the normal salt with CrO,H,, or excess olgesting the normal salt with Cru₂H₃, or excess of Cr₂C₄, with H₂S₂S₄ (v. Schrötter, P. 53, 516; Siewert, A. 126, 97; Schiff, A. 1£4, 167, 172; Recoura, C. R. 112, 1439). According to Traube (A. 66, 87), an acid salt, Cr₂(S₂O₃)₂H₂S₂O₄, is formed by heating either variety of the normal salt with excess of H₂S₂O₄ till vaporisation of the said heating and allowing to cool (Schrötter). acid begins, and allowing to cool (Schrötter [l.c.] regarded this as an insoluble variety of the normal salt); insol. water, not acted on by cold

KOHAq, heated strongly gives Cr₂O₃, SO₂, and O. Cr₄(SO₄), forms many double salts; those with the alkali sulphates have the composition

 $Cr_2(SO_4)_3$. M_2SO_4 . 24aq, and are alums.

Ammonia chrome-alum is ppd. by adding $(NH_d)_2SO_4Aq$ and $Cr_2(SO_4)_2$; also formed by mixing $(NH_d)_2SO_4Aq$ and $Cr_2(SO_4)_2Aq$, and evaporating; also by mixing $Cr_2(SO_4)_2Aq$ (violet) with $(NH_d)_2CrO_4Aq$,

adding a little _______ constant anomals at craporate. Crystallises in ruby-red octahedra; S.G. 1-738. Effloresces slowly in air. Solution in water is violet; at 75° it becomes green, but slowly returns to violet on standing for some weeks (regarding this change v. CHROMIUM SALTS, vol. ii. p. 167).

Potass o'hrome alum is produced similarly to the ammonia salt; also by heating K₂Cr₂O₇ with cono. H₂SO₄, more quickl² in presence of a reducer, e.g. SO₂. Crystallises in large dark-purple octahedra; S. 14.5 in cold water. Solution in water is grey-blue with tinge of red; heated to 70°-80° it becomes green and non-crystallisable, but returns to violet after standcrystallisable, but returns to violet after standing for some weeks. For Soda chrome-alum v. Schrötter (P. 53, 513). For double salts of Cr₂(SO₄)₃ with Al₂(SO₄)₃, Fe₂(SO₄)₃, and Mn₂(SO₄)₃ v. Étard (Bi. [2] 31, 200); for double salts of the form Cr₂(SO₄)₃, 3M₂SO₄, where M = Li₁. K, or Na, v. Warnicke (P. 159, 572). For description of other double salts of Cr₂(SO₄)₃ with alkali sulphates, v. Klobb, C. R. 117, 311 (Abstract in C. J. 64 [ii], 573). Chalt sulphates, —The recoval columns and the salts of Craft sulphates.

Cobalt sulphates.—The normal cobaltous salt CoSO, 7aq occurs native as biberite; prepared by dissolving Co. CoO, or CoCO₃ in dilute H₂SO₄Aq, and evaporating. Forms carmine-red crystals, isomorphous with FeSO, 7aq; S.G. 1918 at 15° (Thorpe a. Watts, C. J. 37, 102). Unchanged in air; loses all water by seating, and gives CoSO₄ as a red powder, not decomposed easily by heat; S.G. 3.472 at 15° (T. a. W., *l.c.*). Klobb (C. R. 114, 836) obtained the anhydrous salt in crystals by mixing CoSO₄. 7aq with excess of (NH₄)₂SO₄ and heating in a partly-closed crucible, out of contact with the gases of the flame, till (NH₄)₂SO₄ was all volatilised. The hexahydrate CoSO₅ caq separates from solutions of Co or CoCO₅ in H₂SO₄Aq at 40°-50°; it is isomorphous with the corresponding salts of Mg Ni and Zn (Maximea). Except the helpstone Mg, Ni, and Zn (Marignac). For other hydrates, with 4aq and aq, v. Fröhde (J. 1866, 244); Vortmann (B. 15, 1888). CoSO, 7aq is insol. alcohol; S. water 30.5 at 10°, 36.4 at 20°, 40 at 29°, 46.3 at 35°, 55.2 at 50°, 60.4 at 60°, 65.7 29°, 46°3 at 35°, 55°2 at 50°, 60°4 at 60°, 65°7 at 70° (stated as parts CoSO, dissolved by 100 parts water; Tobler, A. 95, 193). Thomsen (Th. 3, 516) gives H.F. [Co,S,O,7,H $_{\rm c}$ O] = 234,000. By electrolysing CoSO,4 α q in presence of K $_{\rm c}$ SO, and H $_{\rm c}$ SO, $_{\rm c}$, under special conditions, Marshall obtained Co $_{\rm c}$ (SO, $_{\rm c}$), along with K $_{\rm c}$ So,0 $_{\rm c}$ (C. J. 59, 760) 760).

Basic salts are formed by addition of a little NH₄Aq to hot CoSO₄Aq, also by digesting CoSO₄Aq with CoCO₂ (v. Habermann, M. 5, 442; Athanascoo, C. R. 103, 271).

Aumanascsco, C. R. 103, 271).

For double salts with FeSO₄, MgSO₄, MnSO₄, and ZnSO₄ v. Vohl (4. 94, 57).

Normal cobaltic sulplate Co₂(SO₂), was obtained by Marshall (C. J. 59, 767) by electrolysing CoSO₂Aq in presence of H₂SO₄, under special conditions. A blue crystalline powder, unchanged in a stoppered bottle in ordinary air. but decomposes rapidly in dry air set. air, but decomposes rapidly in dry air; soi. water, with evolution of O; sol. conc. H2SO4; in HClAq forms CoCl, and gives off Cl.

Copper sulphates. Only salts corresponding with the oxide CuO have been isolated. The normal salt CuSO, is obtained by dissolving Cu in hot cone. H2SO4, decenting the hot solution, and allowing to cool; also by adding cone. crystals of CuSO, 5aq to c. 230° as long as they lose weight. Klobb (C. R. 114, 836) obtained CuSO, in crystals by heating a mixture of the Ouso, in crystals by heating a mixture of the hydrated salt and excess of $(NH_1)_2SO_4$ in a partly closed crucible till all $(NH_1)_2SO_4$ had volatilised. A white crystalline powder; S.G. 8-606 at 15° (Thorpe a. Watts, C. J. 37, 102). Partly decomposed at red heat, wholly at white heat, to SO2, O, and CuO. Reduced by heating to redness with charcoal, giving Cu, SO, and CO. At a higher temperature some CuS is said to be formed; also reduced to Cu by heating in H; heated in PH, gives off H,O, and leaves a mixture of sulphide and phosphide of Cu. HCl gas ture of suiphide and phosphide of Cu. HCl gas forms CuCl₂ and H₂SO₄. CuSO₄ acts as a powerful dehydrating agent; it rapidly absorbs water, forming CuSO₄.5aq. H.F.[Cu,S,O'] = 182 500 (Th. 3, 516).

The pentalydrate CuSO₄.5aq (blue vitriol) is prepared by dissolving Cu in hot conc. H₂SO₄, evaporating, and recrystallising from water the colid that convertes. At a 200 there is a very

solid that separates. At. c. 20° there is a very slight reaction, with formation of Cu₂S and CuSO₄; at c. 270° the reaction is Cu+2H₂SO₄ = CuSO₄ + SO₂ + 2H₂O (Pickering, C. J. 33, 112). According to Anthion (R. P. 81, 344), CuSO₄.5aq free from nitrate, is obtained by dissolving Cu in a warm mixture of dilute H₂SO₄Aq and HNO, Acr and crystallising. (For preparation of commercial blue vitriol v. DICTIONARY OF APPLIED CHEMISTRY, vol. i. p. 608.) Large blue, triclinic crystals; S.G. 2.284 at 15° (Thorpe a. Watts, C. J. 37, 102). Solubility in water is given by Poggiale (A. Ch. [3] 8, 463) as follows:-

	8. 		s.	
0° 31 10 36 20 42 30 48 40 56	0.5nq Cus :61 18: :95 20: :31 23: :81 26: :90. 30: :83 34:	20 60° 92 70 55 80 63 90 29 100		CuSO. 38·83 45·06 53·15 64·23 75·25

Gerlach (D. P. J. 181, 129) gives the following

Percentage	S.G.	Percentage	S.G.
CuSO. 5aq	of solution	CuSO. 5aq	of solution
2.	1.0126	14 .	1.0933
4.	1.0254	16 .	1.1063
6.	1.0384	18 .	1.1208
8 .	1.0516	20 .	1.1354
10 .	1.0649	22 .	1.1501
12	1.0785	24	1.1659

Insol. absolute alcohol; S. in 40 p.c. alcohol at 15°=25 (Schiff). Fairly sol. glycerin. Effloresces in dry air, giving off 2H₂O; heated for some time to 100° loses 4H₂O, the last H₂O is removed at c. 230°. For dissociation-pressures of water given off at various temperatures v. Lescœur (C. R. 102, 1466). Solution in HClAq gives CuCl, 2H,O on evaporation. The dry salt in powder, absorbs HCl, the water of crystallisation being set free (Kane, A. 19, 1); several compounds of CuSO, HCl, and H₂O are formed according to Latschinoff (J. R. 1888 [1] 586, 657, 707; abstract in B. 22 Ref. 192). Combines with NH, forming CuSO, 5NH, all water of crystallisation being removed (L., l.c.).

Other hydrated copper sulphates are (1)

CuSO, 6aq and (2) CuSO, 7aq, obtained by Lecoq de Boisbaudran (C. R. 65, 1240), the former by placing a crystal of NiSO, 4aq in a warm supersaturated solution of CuSO₄.5aq, to which a few drops of H₂SO₄Aq had been added, and the latter by placing a crystal of FeSO₄.7aq in the mother-liquor from the first-named hydrate; (3) CuSO, 3aq, by keeping CuSO, 5aq in dry air at 25°-30° (Magnier de la Source, C. R. into H₂SO₄Aq, S.G. 1.7, and washing the pp. with small quantities of absolute alcohol (Thorpe a. Watts, C. J. 37, 104); (4) CuSO, 2aq by keeping the pentahydrate in vacuo at 20° for some days, the pentanydrate in vacuo at 20° for some days, or by pouring conc. CuSO, Aq into cold conc. H_SO, and washing the pp. with absolute alcohol (T. a. W., l.c.); (5) CuSO, aq by heating powdered pentahydrate at 110° till it ceases to lose weight (T. a. W., l.c.). T. a. W. (l.c.) give the S.G. of these hydrates, at 15°, as: monohydrate, 3·289; dihydrate, 2·953; trihydrate, 2·663. Lescœur (C. R. 102, 1466) obtained only the power trie and respectively. the penta-, tri-, and monohydrates.

Double salts with the alkali sulphates, of the

form CuSO4.M2SO4.6aq, are obtained by crystallising mixtures of the constituents in the proper proportions (v. Graham, P. M. 1835. 327, 417; Brunner, P. 15, 476; 32, 221; Pickering, C. J. 49, 1). Vohl (A. 94, 57) has described several Zn, are described (v. Rammelsberg, P. 91, 321; also Lefort, A. Ch. [3] 23, 95; von Hauer, P. 125, 633). Several basic salts of the form 120, 038). Several vasic states of the holm $CuSO_{+}xCuO$, aq are known: -x=1, v. Roucher $(J \cdot P)t$. [3] 37, 249); x=2, v. Reindel $(J \cdot pr. 100, 1; 102, 204)$, Persoz (A. Ch. [3] 25, 257), Shenstone $(U \cdot J \cdot 47, 375)$; x=3, v. Smith $(J \cdot 25, 257)$, $(J \cdot 47, 275)$; $(J \cdot 47,$ snenstone (U. J. 41, 375); x = 3, v. Smith (J. 25, 280), Pickering (C. J. 43, 336; 49, 1), Grimbert a. Barré (J. Ph. [5] 21, 414), Kühn (Ph. C. 1847. 595), Kane (A. 19, 1); x = 4, v. Smith (l.c.); x = 7, v. Pickering (l.c.). For other basic sulphates v. Steinmann (B. 15, 1411), Brunner (P. 15, 476; 32, 221), Becquerel (C. R. 67, 1081), Carcelmann (F. 4. 24) Casselmann (Fr. 4, 24).

Didymium sulphates (v. Marignac, A. Ch.

[3] 58, 148; Cleve, Bl. [2] 21, 246; 39, 151;
Hermann, J. pr. 82, 385; Frerichs a. Smith, A.

191, 348). The normal salt Di₂(SO₄), 8ag crystallises in red, lustrous, monoclinic crystals from a solution of Di₂O₂ or Di₂(O₃), in excess of H₂SO₄Aq; S.G. 2·878; S.H. 1948 (Nilson a. Pettersson, B. 13, 1459). Heated to 300° loses all water of crystallisation, leaving Di_a(SO₄), as a red powder; S.G. 3.735; S.H. 1187 (N. P., l.c.); S. 43.1 at 12°, 11 at 50°, 2 at 100° (Marignac). For effect of heat at various temperatures v. Bailey (C. J. 51, 682). Hydrates with 6aq and aq crystallise from cold saturated solutions of Di₂(SO₄)₃; Marignac (*l.c.*) also obtained a hydrate with 9aq. *Double salts* of the form Di₄(SO₄)₃, M₂SO₄, Saq, where M is an alkali metal, are known. *Basic salts* are formed by heating the normal salt, also by adding a little NH₂Aq to solutions of the normal salt.

The normal auro-auric Gold sulphates. sulphate AuSO, was obtained by Schottländes (A. 217, 312) by evaporating solution of

AuO.H.Du, (v. vajrp) nearly to argness at 250°, and drying in a desiccator over lime. Lustrous, and drying in a desiccator over lime. Lustrous, scarlet prisms, that rapidly absorb moisture from the air, with partial decomposition. A basic salt AuO.H.SO, (auryl sulphate) was obtained (S., l.c.), as a yellow crystalline powder, by heating AuO.NO, with conc. H.SO, at c. 200° (AuO.NO, was formed by dissolving AuO,H, in HNO,Aq S.G. 1.4, filtering through asbestos, and evaporating under reduced pressure over lime and soda). A double salt AuK(SO,), was formed by dissolving KHSO, in solution of AuO.H.SO,, and evaporating at 200° (v. also Allen, C. N. 25, 85).

Indium sulphates (v. Winkler, J. pr. 94, 1; 95, 414; 98, 344; 102, 273; B. Meyer, A. 150, 429). The normal salt In₂(SO₄), is obtained by dissolving In or InO,H, in excess of H2SO,Aq, evaporating to dryness, and heating till excess of acid is mg od dylason, status but the removed; a white, very hygroscopic powder; S.H. 129 (Nilson a. Pettersson, B. 13, 1459). S.G. 8-438 (N. a. P., C. R. 91, 232). By dissolving in water and evaporating, a hydrate with 9ac is obtained as a gummy solid. The solution of In or InO.H. in excess of H.SO.Aq yields a syrupy liquid on evaporation which probably contains an acid salt (? In₂(SO₄), H₂SO₄). By adding (NH₄), SO₄Aq to solution of In₂(SO₄),, and evaporating, the double salt with the composition In (SO,)...(NH,).SO, 24aq is obtained; this salt is an alum; it is sol. in 1 part water at 16°, and in 1 part water at 30°. On evaporating the mother-liquor, the salt In (SO,)...(NH,).2SO,. Saq in btained (Rössler, J. pr. [2] 7, 13). Double salts with K.SO, and Na,SO, crystallising with 8aq, have also been obtained. Iridium sulphates. By treating IrS, with

conc. HNO, Aq, Birnbaum (A. 136, 179) obtained an amorphous, brownish-yellow solid, easily sol. water, probably a sulphate of Ir. The double salt Ir. (SO), 3K, SO, was obtained by Lecoq de Boisbaudran (C. R. 96, 1406, 1551) by fusing KHSO, with Ir compounds, treating with water containing KHSO, dissolving the residue in hot

water, and crystallising; green, translucent crystals, probably regular octahedra; almost insol. saturated KHSO,Aq.

Iron sulphates. I. Ferrous salts. The commal salt, FeSO, is obtained by heating powdered FeSO, 7aq very carefully to 300° till it ceases to lose weight (the heating is best done in a stream of H); at a slightly higher temperature SO2 and O begin to be given off, and finally Fe₂O₂ remains. Fe₂O₃ is a white powder; S.G. 3·346 (Thorpe a. Watts, C. J. 37, 102). Several hydrates of FeSO, are known, ordinary green vitriol being the most common and best examined of these; this heptahydrate, FeSO. 7aq, is best prepared by adding iron filings to warm dilute H,80,Aq until the acid is saturated and a little iron remains undis-solved, boiling for a little, filtering into a vessel that has been rinsed with a very little conc. H.SO., allowing to crystallise, washing the crystals two or three times with very small quantities of cold water, and then with alcohol till all soid is removed, drying at c. 80°, powdering the dry crystals, and strongly pressing between paper or linen. As thus prepared the salt does not readily oxidise in the air. If alcohol is added to the hot solution, filtered from undissolved

iron, FeSu., 7aq is ppd. in minute crystals; if this pp. is washed with alcohol till acid is re-moved and then spread on filter paper, in dry air, till the alcohol has evaporated, the salt is air, till the alcohol has evaporated, the sait is obtained as a bluish white powder, which does not oxidise except in very moist air. Blue-green, monoclinic crystals; S.G. 1-8889 at 4° (Playfair a. Joule, C. J. 1, 138), 1-9854 at 16° (Pape, P. 120, 872). H.F. [Fe,S,O,*,7H*O] = 240,100 (Th. 3, 516). Heated to 100° gives off 6H_O, and at c. 800° leaves FeSO, (v. supra). S. 60°9 at 10°, 70 at 15°, 114-95 at 25°, 227-27 at 46°, 263-15 at 60°, 270·27 at 84°, 370·37 at 90°, 333·33 at 100°, Gerlach (D. P. J. 181, 129) gives the following data (v. also Schiff, D. P. J. 1858. 38):—

G. FeSO,Aq	Petge. FeSO, 7aq	Petge. FeSO
1.0267	5	2.811
1.0537	10	5.784
1.0823	15	8-924
1.1124	20	12.
1.1430	25	15.834
1.1738	80	19.622
1.2063	35	23.672
1.2391	40	27.995

Insol. glacial acetic acid and absolute alcohol. FeSO, 7aq is fairly easily oxidised; exposure to air produces basic ferric sulphates. FeSO, Aq absorbs NO, forming FeSO, xNO (x probably = 1 or \frac{1}{3}; v. Gay, A. Ch. [6] 5, 145, and cf.

NITRIC OXIDE, vol. iii. p. 563). Other hydrates of ferrous sulphate are (1) FeSO, 4 and formed by of jerrous surplinate and it less of Acq at 80° (Regnault, A. Ch. [3] 1, 201), also by exposing finely-powdered FeSO, 7aq over H.SO, in an atmosphere of Oo, until it ceases to lose weight (Thorpe a. Watts, C. J. 37, 102); S.G. 2.227 (T. a. W.); Watts, C. J. 37, 102); S.G. 2:227 (T. a. W.); (2) FeSO₄. 3aq, by evaporating FeSO₄Aq made strongly acid by H₂SO₄ (Kühn, S. 61, 235), also by dissolving FeSO₄. 7aq in hot HClAq and crystallising (Kane, A. 19, 7); (3) FeSO₄. 2aq by boiling the heptahydrate with successive quantities of alcohol; S.G. 2:773 (T. a. W., Lc.); (4) FeSO₂. aq, by heating powdered FeSO₄. 7aq to 120° in H; S.G. 2:994 (T. a. W.; v. also Mitscherlich, P. 18, 152). Several double salts of ferrous sulphate are known; they are generally prepared by crystallising a mixture of the conprepared by crystallising a mixture of the conprepared by crystallising a mixture of the constituent sulphates in the proper proportions. The salts FeSO, M₂SO, 6aq, where M = NH₄, K, Na, or Tl, form blue-green monoclinic crystals (v. Marignao, Ann. M. [5] 9, 19; Schiff, A. 108, 326; Tobler, A. 95, 193; Wilm, A. Ch. [4] 5, 56). For the salts FeSO, MSO, 14aq, where M = Mg or Zn, v. Schiff (l.c.), and Murmanh (W. A. B. 27, 172). For various triple and quadruple salts containing FeSO, alkali sulphates, and sulphates of Mn, Mg, Zn, &c., v. Bette (A. 14, 278) and Vohl (A. 94, 57).

II. Ferric salts. The normal salt Fe(SO), is obtained by adding 1 part cone.

Fe₂(SO₄), is obtained by adding 1 part conc. H₂SO₄ to 5 parts Fe₂SO₄. 7aq dissolved in water, warming, and adding HNO₄Aq little by little till exidation is complete, evaporating to a syrup, and then heating very cautiously so long as soid fumes are given off; on cooling Fe,(SO₄), remains as a white amorphous solid; S.G. 8.097 at 18° (Pettersson, Upsala, Nova acta, 1874). Fairly large quantities of FeSO. 7aq should be used, as evaporation of a dilute solution containing Fe₂(SO₄), produces ppn. of basic sulphates. The hydrate Fe₂(SO₄), 9aq occurs native as

obtained rhombic leaflets of a hydrate with 10aq (J. 1874. 268). Fe₂(SO₄), is slowly sol. in water; the presence of a very small quantity of FeSO₄ causes Fe₂(SO₄), to dissolve rapidly in water (Barreswil, Ph_{\bullet} C. 1845, 604). Fe₃(SO₄), is insol. in conc. H_2 SO₄; it is reduced to FeSO₄ by most metals, more quickly if a little H₂SO₄ is present. Fe.(SO₄), forms several double salts. The sent. Fe₂(SO₄), forms several double salts. compounds Fe₂(SO₄)₂, M₂SO₄. 24aq, where M = NH₄ or K, are alums. Potash iron alum Fe₂(SO₄)₂.K₂SO₄. 24aq is prepared by dissolving parts FeSO₄. 7aq in water, adding 5 parts conc. H2SO4, oxidising by HNO3Aq, adding 8.75 parts K,SO,, and crystallising; or by mixing 10 parts powdered FeSO, 7aq with 4 parts KNO,, slowly adding 5 parts conc. H₂SO,, warming so long as NO₂ is given off, dissolving the residue in 4 times its weight of water at 80°, and allowing to stand at 0° for some time (Heintz, A. 44, 271). The salt slowly decomposes in the air; heated to 80° it gives Fe₂(SO₂)₂₀, basic ferric sulphate, and H₂SO₄; a similar decomposition occurs when an aqueous solution of the salt is heated (Rose, P. 94, 459). Addition of KOHAqto a conc. solution of the salt till a slight permanent pp. is formed, followed by evapora-tion, produces a double salt of K,SO, with a basic ferric sulphate (v. Richter a. Scheerer, P. 87, 73). Ammonia iron alum is formed similarly to the K salt; loses 23H₂O at 150° (v. Lupton, C. J. 28, 201). For double salts with Al₂(SO₄)₃, Cr₂(SO₄)₃, Mn₂(SO₄)₃ and MnSQ₄, v. Etard (Bl. [2] 31, 200). Some double compounds of Fe₂(SO₂), with (NH₃),SO₄, and with FeSO₄ and (NH₃)₂SO₄, are described by Lachaud a. Lepierre (C. R. 114, 915).

A great many basic salts have been described: generally prepared by the action of air on solu-tions of $FeSO_4$. 7aq, or by heating $Fe_2(SO_4)_3Aq$ in sealed tubes (v. Athanasesco, C. R. 103, 271). Pickering (C. J. 37, 807) gives very full references to all the memoirs on those basic salts, and comes to the conclusion that only one exists, viz. 2Fe₂O₃.SO₃; in a later paper (C. J. 43, 182) he gives reasons for writing the formula rather as 6Fe₂O₃.3SO₃.xH₂O, or Fe₂(SO₄)₃.5Fe₂O₃.xH₂O. Lanthanum sulphates. The normal salt

La₂(SO₄), is obtained by dissolving La₂O₅ in excess of H₂SO₄Aq, evaporating, drying the crystals of La2(SO4)3. 9aq that separate, and heating to dull redness; a white powder, S.G. 8.6 (Nilson a. Pettersson, C. R. 91, 232); S.H. 1182 (N. a. P., B. 13, 1459). Much mere sol. cold than hot water; Mosander (P. 11, 406) gives S. 16.6 at 2°-3°, 2.35 at 25°, 87 at 100°. The hydrate with 9aq, formed by the slow evaluations of the O. according to the contraction of the O. according to the O. accordi The hydrate with 9aq, formed by the slow evaporation of La₂O₂ in excess of H₂SO₄Aq, crystalliese in large, lustrous, hexagonal prisms (Topsos); S.G. 2853 (N. a. P., C. R. 91, 232). A hydrate with 6aq was obtained by Frerichs a. Smith (A. 191, 331). Several double salts with the alkali sulphates have been obtained; the principal are M.(NH₁)₂SO₄, 8aq, M.3K₂SO₄, and M.4K₂SO₄, where M = La₂(SO₄)₂ (v. Cleve, Bl. [2] 39, 151; 43, 56). A basic salt was obtained by F. a. S. (l.c. p. 360).

Lead sulphates? The normal salt PbSO₄ occurs in various lead ores. It is obtained as a white, heavy powder, by heating Pb with conc.

white, heavy powder, by heating Pb with conc. H.SO. by the interaction of warm H2SO,Aq

and PbO, or of PbO, and SO, and by ppg. solutions of lead salts by dilute H₂SO₄Aq or solution of a sulphate. PbSO₄ is prepared in small rhombic crystals by melting PbCl₂ with K₂SO₄. and washing with water. S.G. 6.2 (Schröder, P. Ergünz. Bd. 6, 622); 5.96 at 17° (Pettersson, Upsala, Nova Acta, 1874). H.F. [Pb, S, O'] = 216,200 (Th. 3, 516). Nearly insol. water; Rodwell (C. N. 11, 50) says that \$1,062 parts water at 15° dissolves 1 part PbSO. Struve (Fr. 9, 34) gives S. in conc. H.SO, as 13, and S. in Nordhausen acid as 4·19 (v. also Kolb, D. P. J. 209, 268). For solubility in dilute HClAq and HNO₃Aq v. Rodwell (C. J. 15, 59); for S. in various salt solutions v. Löwe (J. 1859, 668); Staedel (J. 1863, 245); Store (C. N. 21, 17); Dibbits (Fr. 1874, 187). Heated to redness, PbSO₄ melts without decomposition, but at a white heat it gives PbO, SO₂, and O (Boussingault, C. R. 64, 1159). Heated in a stream of H, it is reduced to Pb with evolution of SO, H.S. and steam; heated with charcoal, PbO.
PbS, or Pb is formed according to the proportions of the reacting substances. Reduced by Fe or Zn in contact with water. Rubbed with K2CrO, produces PbCrO,; with KIAq yields K₂CrO₄ produces PbCrO₄; with KIAq yields PbI₂, and with NaCl is partly decomposed to PbCl₂ (v. Matthey, Ar. Ph. [3] 13, 233). For reaction when heated in NH₂ v. Rodwell (C. N. 15, 137). A double salt PbSO₄(NH₂)₂SO₄ is formed by adding excess of H₂SO₄Aq to Pb(C₂H₂O₂)₂Aq, neutralising excess of acid by NH₂Aq, boiling, and allowing to cool. An acid salt PbSO₄H₂SO₄, aq was obtained by Schultz (P. 133, 137) by dissolving PbSO₄ in conc. H₂SO₄ and setting aside. A basic salt Ph.SO, and setting aside. A basic salt PbSO, PbO is formed by digesting PbSO, with NH,Aq (Kühn, Ar. Ph. [2] 50, 281).
Lithium sulphates. The normal salt Li,SO, is obtained by dissolving Li,CO, in H,SO,Aq,

evaporating, drying the crystals of Li₂SO, aq that separate, and heating them to c. 135°. S.G. 2·21 at 15° (Brauner, P. M. [5] 11, 67). Melts at 518° (Carnelley, C. J. 38, 280). S. 35°. at 0°, 34°36 at 20°, 32°8 at 45°, 30°3 at 65°, 29°. 24°. Property of the control of the at 0°, 34·36 at 20°, 32·8 at 45°, 30·3 at 65°, 29·24 at 100° (Kremers, A.99, 47). Easily sol. alcohol; insol. SO, (Weber). H.F.[Li²,S,O¹] = 333,200 (Th. 3, 516). Heated in HCl gas below redness gives LiCl (Hensgen, B. 8, 125). The monohydrate Li₂SO, aq crystallises in monoclinic forms (Rammelsberg, P. 129, 311). S.G. 2·052 at 21° (Pettersson, Upsala, Nova Acta, 1874). Effloresces a little in air, gives up water at a little above 130°. An acid salt LiHSO, is obtained by dissolving Ji.SO. in H.SO An S.G. 1·5 tained by dissolving Li, SO, in H, SO, Aq S.G. 1.6 to 1.7 (Schultz, P. 130, 149); prismatic crystals, melting at c. 120° (Lescour, Bl. [2] 24, 516). Double salts with K.SO, are obtained by evaporating mixed solutions of the constituent salts (b. Rammelsberg, A. 128, 311; Schabus, J. 1854. 323). For double salts with Rb₂SO, and Na₂SO, w. Wyrouboff (Bull. soc. mineral. de France, 1882. part 2). Wernicke (P. 159, 576) describes 1882. part 2). Wernicke (P. 159, 576) describes a salt 3Li₂SO₂,Cr₂(SO₂), formed, in green needles, by adding Cr₂O₃ to molten LiHSO₂. Li₂SO₄ does not form alums, nor does it combine with the magnesian sulphates (Rammelsberg, Lc.; Scheibler, J. pr. 67, 485).

Magnesium sulphates. The normal salt MgSO, is obtained by dissolving MgO or MgCO, in H₂SO, Aq (or by heating dolomite till CO₂ is

removed, treating with HClAq, which dissolves CaO, and dissolving the residual MgO in CaO, and dissolving the residual MgO in H.SO.Aq), evaporating, crystallising out MgSQ₁, 7aq, drying this salt, and heating it gradually to c. 300° till it ceases to lose weight. A white solid; S.G. 2.709 at 15° (Thorpe a. Watts, C. J. 37, 102); 2.77 to 2.795 at 14° (Pettersson, Upsala, Nova Acta, 1876). H.F. [Mg,S,O'] = 302,300 (Th. 3, 516). [MgSO',Aq] = 20,765 (Pickering, C. J. 47, 100). Decomposed to MgO, SO₂, and O at c. 360° (v. Bailey, C. J. 51, 682). Not acted on by HCl gas below incipient red heat (Hensgen, B. 9, 1671; 10, 259). The heptahydrate MgSO, 7aq (Epsom same) occurs in many mineral springs, in sea water, and in some rocks. It crystallises at the water, and in some rocks. It crystallises at the ordinary temperature from solutions of MgO or MgCO₂ in H₂SO₄Aq. Translucent, rhombic prisms; from supersaturated solutions crystallises in hexagonal forms, and from solutions lises in hexagonal forms, and from solutions containing some FeSO₄ in monoclinic forms (v. Marignae, Ann. M. [5] 12, 50). S.G. 1-678 at 15° (Thorpe a. Watts, C. J. 37, 102); 1-683 at 4° (Playfair a. Joule, C. J. 1, 138). H.F. [Mg,S,O',7H°O] = 326,400 (Th. 3, 516). Melts at 70° (Tilder, C. J. 45, 267); gives up 6H_cO by prolonged heating at 150°-160°, and all water of crystallisation at c. 280° (v. Pickering, C. J. 47, 100). The following data for solubility in water are calculated by Multier from observawater are calculated by Mulder from observations by Gay-Lussac, Tobler, and others :-

8. at 15° in 10 p.c. alcohol 39.3, 20 p.c. alcohol 21.3, 40 p.c. alcohol 1.62 (Schiff, A. 118, 365). Heated with NaCl gives off HCl, leaving Na SO, MgCl, and some MgSO, (Ramon de Luna, J. pr. 66, 256). Decomposed, almost entirely, by heating in steam, giving off H₂SO, and leaving MgO (Clemm, J. 1864. 764). Strongly heated with charcoal gives off SO₂ and CO₂ (or CO), and leaves MgO. Mixed with NaCl and heated in Steam gives Na₂SO₄, MgO, and HCl.
Other hydrates of magnesium sulphate. (1)

MgSO, aq occurs native as kiescrite, S.G. 2-281 at 16° (Pape, P. 120, 869); dissolves slowly in cold wafer, easily in boiling water, forming MgSO, 7aq; prepared by heating the heptahydrate for a long time at 150°-160° (Pickering, C. J. 47, 100); S.G. 2-445 (Thorpe a. Watts, C. J. 37, 102). (2) MgSO, 6aq, by crystallising a solution of the heptahydrate above 40°; S.G. 1-734 (T. a. W., I.c.). (3) MgSO, 5aq, by drying the heptahydrate over conc. H₂SO₄; S.G. 1-869 (T. a. W., I.c.). (4) MgSO, 2aq, by boiling powdered MgSO, 7aq with absolute alcohol; S.G. 2-373 (T. a. W., I.c.). (5) According to Jacquelaine (A. Ch. [3] 32, 201), the hydrates 4M. 7aq, 4M.9aq, and 2M.5aq exist (M=MgSO).

Asid salts. Schiff (A. 106, 115) obtained deliquescent, hexagonal plates, MgSO, H₂SO₄; from a solution of MgSO, in hot conc. H₂SO₄; according to Schultz (P. 130, 149), the crysfals are MgSO, 3H₂SO₄. MgSO4. aq occurs native as kieserite. S.G. 2.281.

are MgSO, 3H₂SO, With K₂SO, or (NH₁)₂SO, to form compounds MgSO₄, M₂SO₄, 6aq; by crystallising mixtures of the component salts in tallising mixtures of the component salts in proper proportion. For solubility and S.G. of solution of the K.SO. compound, v. Tobler (A. 95, 193), Schiff (A. 113, 183), Gerlach (Fr. 8, 287). The compound of MgSO. and Na.SO. contains 4aq (cf. van't Hoff a. Deventer, B. 19, 2144). The compound MgSO. KCl. 3aq occurs native as kaintie (v. Reichardt, Ar. Ph. 159, 204; Erlenmeyer, B. 2, 289). A double salt MgSO. Al.(SO.). aRL20 occurs as feather alum, and wickeringite. Some triple salts of McSO. and pickeringite. Some triple salts of MgSO₄ with CaSO₄ and K₂SO₄ cocur as minerals (v. Reichardt, Ar. Ph. 159, 204; Precht, B. 14, 2138)

Manganese sulphates. salts. The normal salt MnSO, is obtained by dissolving MnCO₃ or Mn in warm dilute H₂SO₄Aq, crystallising out MnSO, 5aq, drying this salt, and heating to c. 280° until it ceases to lose and heating to c. 280° until it ceases to lose weight. A white salt, with very faint rose tint; S.G. 3-282 (Thorpe a. Watts, C. J. 37, 113). H.F. [Mn,S,O] = 249,900 (Th. 3, 516). S. 56-5 at 6.3°, 60 at 18.7°, 68.7 at 37.5°, 67 at 75° (Brandes, P. 20, 575). Decomposed by heating to full redness, giving off SO₂ and O, and leaving Mn₃O₄; heated in steam is said to give an oxysulphide Mn.OS (Arfvedson, P. 1, 50).

Hydrates of manganous sulphate. (1)
MnSO₄.7aq separates from solutions of Mn or MnCO, in H_2 SO, Aq below 6° (Mitscherlich, P. 25, 287; Classen, Ar. Ph. [3] 25, 310). Very pale se-coloured, monoclinic crystals; isomorphous with FeSO, 7aq. Very sol. water; S. at 18.5° c. 200 (Jahn, A. 28, 110). According to Etard (C. R. 86, 1399), solubility increases from 0°-55°, and decreases from 55°-145°; the from 0°-55°, and decreases from 55°-145°; the changes are probably due to the formation of different hydrates. (2) MnSO, 5aq, obtained by crystallising between 7° and 20°, or by treating a conc. solution of MnSO, with 95 p.c. alcohol and allowing to crystallise slowly (Claassen, Ar. Ph. [3] 25, 340). S.G. 2·103 (Thorpe a. Watts, C. J. 37, 113). H.F. [Mn,S,O.5ETO] = 263,600 (Th. 3, 516). (3) MnSO, 4aq, obtained by crystallising between 20° and 30° (C., Lc.; Mitscherlich, P. 25, 287). *S.G. 2·261 (Topsoë, C. C. 4, 76). This is the main constituent of ordinary manganese subbate. Mulder gives ordinary manganese sulphate. Mulder gives solubilities as follows:—

Temp.	S. MnSO, 4aq	Tem	B. MnSO. 480
0#	55.4	50°	74.8
5	58.2	54	75.3
10	63.8	63.5	61.3
20	66.3	64	61.5
25	68.5	85	61.3
30	70.4	90	60.3
85	71.9	95	57:9
40	73.1	100	52.9
, 4 5	74.0	•	

Insol. absolute alcohol (cf. Schiff, A. 118, 365). (4) MnSO₄. 2aq, obtained by boiling the powdered pentahydrate with absolute alcohol; also by pouring a saturated solution of the pentahydrate into cone. H₂SO₄; S.G. 2·526 (T. a. W., *l.c.*). (5) MnSO₄, aq, obtained by heating the pentahydrate at 100° till it ceases to lose weight; S.G. 2·845 (T. a. W., *l.c.*).

hydrate at 100 till it ceases to lose weight; S.G. 2-845 (T. a. W., l.c.).

Linebarger (Am. 15, 225) has obtained hydrates of MnSO, with 1, 2, 3, 4, 5, 6, and 7 H.O. Below - 10° mixtures of the heptahydrate and ice separate from MnSO, as; above 117° only MnSO, separates. The solubilities of the various hydrates are discussed; the more water in the hydrate, the more soluble it is.

Acid salts MnSO, H,SO, and MnSO, 3H,SO, were obtained by Schultz (P. 130, 149) by dissolving the normal salt in hot cone. H,SO,.

Basic salts are formed by adding a little warm KOHAq to a large excess of boiling MnSO₄Aq (V. Gorgeu, C. R. 94, 1425).

Double salts; (1) with sulphates of Cu, Fe, Mg,

Double salts; (1) with sulphates of Cu, Fe, Mg, and Zn to form salts MnSO, MSO, MSO, MHQO, WHQO (v. Rammelsberg, P. 91, 321; Vohl, A. 94, 73).

(2) With Al₄(SO₄)₃, Fe₂(SO₄)₃, and Cr₂(SO₄)₃ v. Etard (C. R. 86, 1399; 87, 602).

(3) With alkali sulphates to form MnSO, M₂SO, 4aq or 6aq (v. Marignao, Ann. M. [5] 9, 1; Pierre, A. Ch. [3] 16, 239; von Hauer, J. pr. 74, 431). For various triple salts of MnSO₄ with alkali sulphates and CuSO₄, MgSO₄, &c.; v. Vohl (A. 94, 57).

II. Manganic salts.—The normal salt Mn₂(SO₄), is obtained by the action of hot conc. H₂SO₄ on MnO₂. Carius (A. 98, 53) recommends to prepare pure MnO₂ by passing Cl into. NaOHAq containing MnCO₂ in suspension, to wash and dry the MnO₂, to rub up to a paste with conc. H₂SO₄, and heat gradually to 110° till O is given off and the mass becomes greyviolet, then to heat to c. 135°-140° till the whole is liquid, to pour the solid that forms as the liquid partially cools on to warm unglazed porcelain, after H₂SO₄ has become absorbed to mix with a little conc. HNO₂Aq and allow to drain on the porcelain, to repeat this treatment with HNO₂ six or eight times, and finally to heat at 150° till all HNO₂ is removed. Franke (J. pr. [2] 36, 451) detained Mn₂(SO₄), by heating 8 g. KMnO₄ with 100 c.c. conc. H₂SO₄ at 100° for some time. A dark-green powder; Franke describes it as green crystals. Decomposed above 160°, giving MnSO₄. Insol. conc. H₂SO₄ or conc. HNO₂AQ. Sol. conc. HClAq to a brown liquid, which gives off Cl whon warmed. Mn₂(SO₄), is very hygroscopic; quickly decomposed by water, with separation of MnO₂xH₂O (Carius, I.c.).

Forms double salts with Al₂(SO₄)₂, Fe₂(SO₄)₂, and Cr₂(SO₄)₂ (v. Étard, C. R. 86, 1399). The double compounds of Mn₂(SO₄)₂ with alkali sul-

phates—Mn₁(SO₄), M₂SO₄, 24aq—are alums. According to Fremy (C. R. 82, 1231), the salt Mn(SO₄)₂, manganese disulphate, corresponding with MnO₂, is formed by decomposing KMnO₄ by a considerable excess of cold conc. H₂SO₄ (cf. Franke, J. pr. [2] 36, 453).

Franke, J. pr. [2] 36, 453).

Mercury sulphates. I. Mercurous salts.

The normal salt Hg₂SO₄ is obtained by gently warming equal weights of Hg and conc. H₂SO₄. removing the white solid so produced before the whole of the Hg is changed, washing with cold water, and drying at a low temperature. Divers a. Shimidzu (C. J. 47, 639) recommend to mix Hg with fuming sulphuric acid rich in SO, in a covered dish, in a cool place, adding a little more Hg from time to time till there is sufficient to saturate the SO, in the acid, but avoiding excess, and when the Hg is all converted into Hg₂SO₄ to set the dish in a warm place to expel SO₂. Hg₂SO₄ is also obtained by adding 6 pts. water to 18 pts. HgSO, and rubbing with 11 pts. Hg (Planche, A. 66, 168). Also by ppg. HgNO, Aq by dilute H₂SO Aq or solution of a sulphate; or by rubbing together HgNO, and Na₂SO, and washing with cold water (H. Rose; Stoedeler, A. 87, 129). A white powder, consisting of mono-clinic prisms (S., l.c.); S. G. 7-56 (Playfair a. Joule, C. S. Mem. 2, 401). Sl. sol. water; S. in cold water '2, in boiling water '33; more sol. dilute HNO₃Aq; sol. conc. hot H₂SO₄, crystallising out on cooling. Hg₂SO₄ becomes grey on exposure to light (v. Buchner, Chem. Zeitung, 10, 759): hence the salt should be kept in the dark. Hg₂SO₄ melts to a reddish liquid, and decomposes at a higher temperature, giving off SO₂ and O, and also partially subliming. Slowly changed by boiling water to an acid salt, and a yellow powder which is probably a basic salt (v. Kane, P. 42, 367). An acid salt Hg.SO.,H.SO. is said to be formed by the prolonged reaction of conc. H₂SO₄ containing a drop of HNO₄Aq on Hg (Braham, C. N. 42, 163). A double salt Hg₂SO₄.2HgSO₄ was obtained by Brooks (P. 66,

Hg_BO_.211gSO, was obtained by House (r. ob. 63) by gently warming mercuro-mercuric nitrate (formed by warming 2 pts. Hg with 3 pts. HNO₃Aq S.G. 1.2) with Na₂SO, 4a. II. Mercuric salts. The normal salt HgSO, is obtained by the reaction of 6 pts. boiling conc. H₂SO, with 5 pts. Hg, till SO₂ ecases to be evolved, and a little of the white solid produced gives no pp. of HgCl when dropped into dilute HClAq; the white mass is gontly warmed till acid fumes cease to be given off. A white powder; S.G. 6466 (Playfair a. Joule, C. S., Mem. 2, 401). Becomes yellow, then red when heated; decomposes at red heat to Hg, O, and SO₂, a little HgSO, subliming (Mohr, A. 31, 180). Decomposed by water to a yellow basic salt and H₂SO₄Aq. Hot HgSO, absorbs HCl and HBr gases; according Dittle (A. Ch. 15) 17, 120) the compounds HgSO₂.2HCl and HgSO₂.2HCl is said to be sol. water without formation of basic salts, and HgSO₂.2HCl is said to sublime unchanged when heated. Solution of HgSO₄ in H₂SO₄Aq is said to react the Hg, 10 form the compound (3HgOO₃).Hg, P(H. Rose, P. 40, 75). Monohydrated mercuric sulphate HgSO₄-aq was obtained by Eisfeldt (Ar. Ph. [2] 76, 16) by covering a thin layer of HgSO₄ with the calculated quantity of water. The basic salt HgSO₄.2HgO

(=8HgO.SO.) is obtained by the action of hot water on HgSO, also by adding Na, SO, Aq to bot Hg(NO₃)₂Aq; a citron-yellow powder, J.G. 644; nearly insol. water (v. Cameron, An. 1880-144). Decomposed by Cl at the ordinary emperature. Absorbs HCl and HBr, forming IgSO.2HgO.6HOl(or 6HBr) (Ditte, l.c.). This asic salt was formerly known as minerale urpethum or turbith mineral (from its resemlance to a coloured gum obtained from an lance to a coloured gum obtained from an Uriental creeping plant [Ipomaca turpethum]). Hopkins (Am. S. 18, 364) described another basic salt 3HgSO, HgO = 4HgO.3SO, Double salts. — (1) HgSO, (NH), SO, xHO and HgSO, K,SO, xHO (v. Hirzel, J. 1850. 322). (2) HgSO, HgI, (v. Souville, J. Ph. 26, 474). (3) 2HgSO, HgS (v. Jacobsen, P. 68, 411). Molybdenum sulphates. By evaporating a solution of MoO, in conc. H₂SO, Schultz-Sellack (B. 4, 14) obtained white lustrous crystals of MoO, SO, the compound MoO, 3SO, 2aq, de-

of MoO, SO,; the compound MoO, SSO, 2aq, described by Anderson (B. J. 22, 161), could not be

obtained by S-S.

Nickel sulphates. The normal salt NiSO, is formed, as a clear yellow powder, by heating powdered NiSO, xaq (v. infra) to c. 800°. The salt is obtained in crystals, regular outsted an by heating NiSO., NiO, or NiOO, with five or six times its weight of fused (NH₁)₂SO., separating the yellow crystals of the double salt SNiSO₄.2(NH₁)₂SO, that form, and heating these in presence of some (NH₁)₂SO, in a partly closed crucible out of contact with the gases of the flame till all the ammonium salt is removed; S.G. of crystals 3.67 at 20° (Lepierre a. Lachaud, C. R. 115, 115; Klobb, C. R. 114, 836). Tobler (A. 95, 193) gives solubilities of NiSO, as fol-

Temp.	S.	Temp.	S.

81	45·8	70	61.9

The hexahydrate NiSO, 6aq is obtained by dissolving Ni, NiO, or NiCO, in excess of H.SO,Aq, evaporating, and crystallising. At the ordinary temperature; bluish tetragonal pyramids separate (Brooke a. Phillips, P. 6, 193); greenish monoclinic crystals separate from warm solutions (Pierre, A. Ch. [3] 16, 252). The salt is, therefore, dimorphous (Marignac, A. 97, 294; cf. Mitscherlich, P. 12, 144; also Lecoq de Boisbaudran, A. Ch. [4] 9, 173). By dissolving this hydrate in water, and crystallising at 15°. 20°, emerald-green rhombic prisms of the heptahydrate NiSO. 7aq are obtained, isomorphous with MgSO. 7aq; melts at 98°-100° (Tilden, C. J. 45, 267). When this hydrate is heated to -103° it loses of 100 and leaves the monohydrate Niso, aq. . By passing NH, into Niso, Aq, compounds of the form Niso, xNH, yH, 0 are obtained (x=4, 5, and 6; v. F. Rose, Ammon. Kobaliverbind. [Heidelberg, 1871] 27; also P.

Double salts. (1) With (NH₁)₂SO₄, K₂SO₄, and TL₂SO₄ to form NiSO₄, M₂SO₄, 6aq (v. F. Rose, l.c.; Link, Crell's Ann. 1796 [1] 32; Werther, J. pr. 92, 182). (2) With BeSO₄ to form various compounds [Klatza Them disconnected to the second transfer of them disconnected to the second transfer of them disconnected to the second transfer of the secon sompounds (Klatzo, Über die Constant. der Beritlerie, Lorpat, 1808). (3) With CuSO., CoSO., FeSO., MgSO., MnSO., and with some of these and also alkali sulphates (v. Pierre, A. Ch. [3] 16, 253; Lecoq de Boisbaudran, C. R.

Basic salts are formed by the gradual reaction of NiSO, Aq with NiCO, and by adding a little NH, Aq to boiling NiSO, Aq (Habermann, M. 5, 440

Palladium sulphates. The normal palladous salt PdSO. 2aq is obtained in brown crystals by evaporating a solution of Pd in H₂SO.Aq containing HNO. Addition of a little KOHAq to a cone solution in water of the normal salt ppts. a basic salt PdSO₄.7PdO.6aq (v. Kane, B. J.

24, 236).
Platinum sulphates. By dissolving PtO₂H. in dilute H.SO, Aq, Berzelius (Lehrbuch [5th ed.] in diute H₂SO₄Aq, Berzelius (Lehrbuch [5th ed.] 8, 987) obtained a dark syrup which probably contained platinous sulphate PtSO₄. Platinic sulphate Pt(SO₄)₂ was obtained by Berzelius (L.c., p. 989) by evaporating PtCl₄ with conc. H₂SO₄ (1 part acid for 1 part Pt), as an almost black solid. E. Davy (T. 1820) obtained the salt by oxidising PtS₂ by fuming HNO₃. Prost (Bl. [2] 46, 156) obtained a basic salt by allowing an end of salt that the salt of the acid solution of Pt(SO4)2 to stand for some days; Prost also describes several double salts of Pt(SO4)2 with alkali sulphates.

Potassium sulphates. The normal salt K₂SO₄ is found in the lava from Vesuvius, in small quantities in sea water, and in some mineral springs, in combination with MgSO, and MgCl, as kaintle (K,SO,MgSO,MgSO,MgCl, Saq), in combination with MgSo, and CaSO, as polyhalite (K,SO,MgSO,2CaSO,2aq), and as alum. K,SO, is prepared by decomposing KCl by H,SO, by neutralising H,SO,Aq by KOH or K,OO, and evaporating (for the preparation of K2SO, on the large scale v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 279). K,SO, forms in white, hard, four-sided, trimetric prisms, unchanged in air. four-sided, trimetric prisms, unchanged in air, S.G. 2.656 at 4° (Playfair a. Joule, C. J. 1, 132); for S.G. at various temperatures from 0° to 100° v. Spring, B. 15, 1940. Melts above 861° (Carnelley, Melting-and Boiling-Point Tables, 1, 33); melts at 1973° according to V. Meyer a. Riddle (B. 26, 2443). H.F. [K', S, O'] = 344,600 (Th. 3, 516); [K'SO', Aq] = -6167 (Pickering, C. J. 47, 98). Mulder (Scheikund. Verhandg. 1864. 49) gives solubilities in water as follows: gives solubilities in water as follows:-

Temp.	S.	Temp.	8.
5°	9.1	55°	16.8
10	9.7	60	17.8
15	10.3	65	18.8
20	10.9	70	19.8
25	11.6	75	20.8
80	12.3	80	21.8
85	13.1	85	.22.8
40	14.0	90	23.9
45	14.9	● 95	25.0
50	15.8	100	26.2

Gerlach (Fr. 8, 827) gives S.G. of K,SQ,Aq as

Pctge.K,SO.	S.G. K.SO. Aq 1.00829	Petge.K.SO.	S.G. K.SO. Aq 1:04947
2	1.01635	7	1.05790
8	1.02450	8	1.06644
4	1.03277	9	1.07499
5	1.04105	9.92 (satd	.) 1.08805

Insol, absolute alcohol; sol. aqueous alcohol in proportion to amount of water present (v. Schiff, A. 118, 362). Insol. KOHAq 1.32 S.G.; sl. sol. KOHAq 20 p.c. S. in saturated NH₃Aq = 0365 (Giraud, Bl. [2] 43, 552). S. in glycerin (S.G. 1·225) at ordinary temperature = 1·32 (Vogel, N. R. P. 16, 557). More sol. in solution of CuSO, MgSO, or Na SO, than in water. Reacts with strong acids to give KHSO, (for thermal measurements v. Berthelot, Essai de méc. chimique, 1, 389). Dissolves in hot conc. HNO,Aq, KHSO, separates on cooling, then KNO, and then a compound of K,SO, with HNO, ; H, PO, Aq reacts similarly (v. Jacquelain, Biedermann's Techn. Chem. J. 4, 62). Absorbs HCl gas when heated, forming KCl and KHSO. (Thomas, C. J. 33, 372; Hensgen, B. 9, 1671; 10, 259). Decomposed by heating with NH.Cl, giving KCl (H. Rose, P. 64, 568). Heated to redness with iron filings gives KOH mixed with Fe₂O₃ and FeS (d'Heureuse, P. 75, 255). Reduced to sulphide (or KSH) by heating in CO; to KSH and KOH by heating in H (v. Berthelot, C. R. 110, 1106). Sulphur reacts at full red heat, giving SO₂ and polysulphides of K (Berthelot, C. R. 96, 303). SO₂ is without action at a red

Double salts. (1) With $Al_2(SO_4)_3$, $Cr_2(SO_1)_3$, and $Fe_2(SO_4)_3$ to form K_2SO_4 , $M_2(SO_4)_3$, 24aq; v. potash alum, potash chrome-alum and potash iron-alum, under Aluminium sulphates (p. 568), FORMALIM, under ALUMINIUM SULPHATES (p. 568), CHROMIUM SULPHATES (p. 577), and IRON SULPHATES (p. 572). (2) With sulphates of Ce and Di respectively, to form 3K_SO_4M_(SO_4), (v. Cleve, Bl. [2] 43, 359; Czudnowitz, J. pr. 82, 129; Hermann, J. pr. 82, 385); also the salt 2K_SO_4Ce(SO_4)... 2aq (Marignac, Ann. M. [5] 15, 275). (3) With sulphates of Cd, Co, Cu, Fe, Mg, Mn, Ni, Zn to form K_SO_4MSO_4. 6aq (v. Graham, P. M. 1835, 327. 417; Brunner, P. 15, 476; 32. P. M. 1835. 327, 417; Brunner, P. 15, 476; 32, 221; Pickering, C. J. 49, 1; Tobler, A. 95, 193; 221; Pickering, C. J. 49, 1; Tobler, A. 95, 193; Schiff, A. 108, 326; 113, 183; Gerlach, Fr. 8, 287; Marignao, Ann. M. [5] 9, 19; Wilm, A. Ch. [4] 5, 56; Pierre, A. Ch. [3] 16, 239; von Hauer, J. pr. 74, 431; Werther, J. pr. 92, 132). (4) K.SO.,BeSO., 2aq (Awdojeff, P. 56, 101). (5) K.SO.,Na.SO, (Penny, P. M. [4] 10, 401; Mitscherlich, P. 58, 468; von Hauer, J. pr. 83, 256).

Stol.

The acid salt KHSO, occurs in some volcanic districts as miserits; it is formed by heating 13 parts K,SO, with 8 parts conc. H,SO, or by heating KNO, and conc. H.SO, in the ratio KNO, H.SO. Crystallises in white rhombic KNO.:H.SO. Crystallises in white rhombic forms, S.G. 2.273; also in monoclinic forms, S.G. 2245 (v. Wyrouboff; abstract in C. J. 50, 665).

Molts at c. 200°. Easily sol. water; Kremers gives S. 33°9 at 0°, 48 at 20°, 62°9 at 40°, 114 at 100°. An aqueous solution is said to deposit, first K2SO, then KHSO, K2SO, and then KHSO; by evaporating KHSO, Aq at a low temperature until a solid mass formed on removing the flame, arborescent and very deliquescent crystals formed on the surface of the solid, which were 2KHSO₄.11H₂O according to Senderens (Bl. [3]

Other acid salts. (1) KHSO₄,K₂SO₄, obtained by evaporating KHSO₄Aq. (2) 2KHSO₄,K₂SO₄, orystallising from K₂SO₄ in H₂SO₄Aq (Phillips, J. pr. [2] 1, 429; Marignae, Ann. M. [5] 9, 7). (8) KHSO₄,H₂SO₄, formed by heating K₂SO₄ with

less than 5 parts conc. H.SO. (Schultz, P. 133.

137).

Rhodium sulphates. The normal rhodic sulphate Rh₂(SO₄), is obtained by dissolving Rh₂O₄, xaq in H₂SO₄Aq, evaporating, and heating to 400° till excess of acid is removed; a red powder, decomposed by hot water to the yellow basic salt Rh₂(SO₁)₃.Rh₂O₃ (Leidié, C. R. 107, 234). Claus (Beiträge zur Chemie der Platinmetalle [Dorpat, 1854]) obtained the hydrate Rh₂(SO₄)₃. 12aq, as a pale-yellow crystalline salt, by crystallising a solution of Rh.O. xaq in H.SO, Aq, and washing with alcohol. The double salt Rh (SO4) 3K SO4 was obtained by Claus (l.c.) by evaporating a solution of the constituent salts in the ratio Rh (SO₄)₃:5K₂SO₄. The double salt Rh₂(SO₄)₃:Na₂SO₄ was obtained by Bunsen (A. 146, 265; v. also Seubert a. Kobbé, B. 23, RhSO₂.0Na₂SO₃.9aq (formed by heating RhCl₂Aq for some time with NaHSO₃).

Rubidium sulphates. The normal salt

Rb2SO4 is obtained by neutralising H2SO Aq by Rb₂CO₂ and evaporating; it crystallises in transparent, hexagonal forms, unchanged in air. S. 42.4 at 70°. S.G. 3.6438 at 0°; 3.6256 at 50°; 3-6036 at 100° (Spring, B. 15, 1940). If excess of H₂SO₄Aq is used, the acid salt RbHSO₄ separates in rhombic prisms (Kirchoff a. Bunsen, P. 115, 584).

Double salts. (1) With Li₂SO₄ to form RbLiSO₄ (Wyrouboff, Bl. [2] 48, 184, 630). (2) With CaSO₄ and PbSO₄ to form the compounds (2) With Caso, and Paso, to form the combounds Rb₂SO, 2MSO, xag (Ditte, C. R. 89, 641). (3) With Al₂(SO₄), to form rubidium alum Al₂(SO₄), Rb₂SO₄. 24aq (Bunsen, P. 119, 1; Godefiroy, A. 181, 176; Redtenbacher, J. pr. 95, 143).

Ruthenium sulphate. Normal ruthenic sulphate Ru(SO₄)₂ is obtained by oxidising RuS₄ (formed by prolonged action of H₂S on RuCl₂Aq) by conc. HNO, Aq, and evaporating off excess of acid. An amorphous, brownish-yellow, very hygroscopic solid. Strongly heated gives RuO,

(Claus, J. pr. 42, 364).
Silver sulphates. The normal salt Ag, 80, is obtained by heating finely divided Ag with exobtained by neating inner divided Ag with excess of conc. H₂SO₄, by neutralising H₂SO₄Aq by Ag₂O or Ag₂CO₃ and evaporating, by evaporating AgNO₃ with H₂SO₄Aq, or by ppg. AgNO₃Aq by Na₂SO₄Aq. Small, white, lustrous, rhombic crystals, isomorphous with Na₂SO₄ (Mitsoherlich, 2012) and 1952 (1952) and 1952 (crystals, isomorphous with Na₂SO₄ (altesenericit, P. 12, 138; 25, 301). S. 1-15 cold water, 1-45 at 100° (Wenzel, P. 82, 136). S.G. 5-322 (Playfair a. Joule, C. S. Mem. 2, 401), 5-425 when fused (Schröder, P. 106, 226). Decrepitates when heated to 300°; melts at 645° (Carnelley, C. 1000). when heaved to 500°s; meits at 645° (Carnelley, C. J. 33, 279). Decomposed at very high temperature, giving Ag, SO₂, and O. Reduced to Ag by heating in H, with C, or in CO (Stammer, J. pr. 11, 70). Absorbs 2NH, (H. Rose, P. 20, 153).

20, 153).

Acid salts are obtained by dissolving Ag₂SO₄ in different quantities of H₂SO₄Aq and crystallising; Schultz (P. 133, 187) describes (1) AgHSO₄, (2) 2Ag₂SO₄.3H₂SO₄.2aq, (3) Ag₂SO₄.3H₂SO₄.2aq. (3) Ag₂SO₄.3H₂SO₄.2aq. (3) Ag₂SO₄.3H₂SO₄.2aq. (3) Ag₂SO₄.3H₂SO₄.2aq. (3) Ag₂SO₄.3H₂SO₄.2aq. (3) Ag₂SO₄.3G₄.

Forms a double salt Ag.SO.Al. (SO.) .. 24aq; this salt is an alum (v. Church a. Northcote, C. N. 9, 155). Also combines with Ag₂S and with K₂SO₄ (Berzelius; H. Rose, P. 53, 463)

S dium sulphates. The normal salt Na2SO. occurs native as thenardite, in combination with CaSO, as glauberite, and with MgSO, as loweite; the salt also occurs in sea water and in many mineral springs. It is prepared by adding H2SO to NaCl in the ratio NaCl:H2SO, and strongly the NaHSO, thus produced; also by the reaction between NaCl, SO₂, steam and O at 400° 450°; 2NaCl + SO₂ + O + H₂O - Na,SO, + 2HCl (for the application of these processes on the large scale v. Dictionary of APPLIED CHEMISTRY, vol. iii. p. 439). Na.SO, is also obtained in the decomposition of NH.Cl. or NaNO₂, by H₂SO₄; it is formed by neutralising H₂SO₄Aq by NaOHAq or Na₂CO₃, evaporating, and heating to redness the crystals of Na, SO, xaq that separate. Na, SO, is a white amorphous powder; S.G. 2.597 (Playfair a. Joule, C. S. Mem. 2, 401); 2.631 (Karsten, S. 65, 894). Obtained in rhombic crystals, isomorphous with Ag₂SO₄ (Mitscherlich, P. 12, 138; 25, 301), by heating to 40° a solution saturated at 33° B.G. 2.6618, or 2.6637 crystallised at 110° (Nicol, P. M. [5] 15, 94). Dissolves in water with production of heat; according to Berthelot (C. R. 78, 1722) [Na°SO', Aq] = 780 at 21.2°, but -100 at 8°; Pickering (C. J. 45, 686) thinks that two modifications of Na,SO, exist; the salt dried at 100° or 150° gave [Na°SO', Aq] = 57 at 20.4°, but the half tipe to townsorthing a varying from 250°. after heating to temperatures varying from 250° to the melting-point the heat of solution was $[Na^2SO^4,Aq] = 760$. Thomsen (Th. 3, 516) gives H.F. $[Na^2,S,O^4] = 328,600$. Tilden (Pr. 35, 345)gives solubilities as follows: 5 at 0°, 788 at 34°, 42°7 at 100°, 41°95 at 120°, 42 at 140°, 42°9 at 160°, 44°25 at 180°, 46°4 at 230°. Etard (C. R. 113, 854) says that S. increases from 33° to 80°, remains constant to 230°, and then decreases to 820° (v. also Löwel, A. Ch. [3] 33, 334; 49, 32; Gernez, C. R. 60, 833; de Coppet, Bl. [2] 17, 146). For S.H. and expansion of Na₂SO₄Aq v. Thomsen (P. 142, 837) and Marignae (A. Ch. [4] 22, 415). Na,SO, melts at 861° (Carnelley, C. J. 33, 280); at 843° (V. Meyer a. Riddle, B. 26, 2448). S.G. at melting-point = 2·104 (Braun, B. 7, 958)

Heated with charcoal out of air Na₂S0, is reduced to Na₂S; Gay-Lussac (A. Ch. [2] 11, 312) says polysulphides are also formed; CO₂ is evolved, but no CO (Unger, A. 63, 240; Scheurer-Kestner, A. Ch. [4] 1, 412; Stromeyer, A. 107, 361); heated to bright redness with O in a vessel containing air, Na₂S is formed and CO evolved (Berthelot, C. R. 1.0, 1106). Reduced to sulphide by heating to bright redness in carbon monoxide (B., l.c.); reduction by hydrogen begins at c. 500°, the products are Na₂S, NaSH, NaOH, H.O. and H.S (B., Le.). Heated with hydrogen chloride, NaCl is formed (Bousingault, C. R. 78, 593); boiling HClAq produces NaCl and NaHSO, (Thomas, C. J. 33, 373). A little NaCl is formed by heating with ammonium chloride (Nicholson, C. N. 26, 47). Boiled with barium carbonate some Na₂O₂ and BaSO, are formed; after a time a condition of equilibrium is attained. A very little NaOHAq is produced by boiling for some time with milk of lime; ander increased pressure NaOHAq is formed

(v. Scheure: Kestner, A. Ch. [4] 1, 412). Not decomposed by heating strongly with calcium carbonate (S.-K., l.c.). When a mixture of Na, 30, and alumina is heated in steam, 30, is given off and södium aluminate remains; presence of charcoal hastens the reaction (Wagner). According to Stromeyer (A. 107, 361) fusion with iron produces Fe, 0,, Na, 0, and Na, 3.2 FeS. The final products of heating with silica and carbon in a closed crucible are Na, 0.2 SiO₂, S, CO₂ and CO (S.-K., C. R. 114, 117).

Hydrates of Na.SO. (1) The hepta-hydrate Na.SO. Taq is obtained by melting Glauber's salt Na.SO. 10aq in its water of crystallisation, heating to boiling, at once closing the vessel, and shaking repeatedly as the liquid cools till 18° is reached; Na SO, separates at first but dissolves again, and below 18° Na SO, 7aq separates (Löwel, A. Ch. [3] 33, 334; 49, 32). The following method gives better results (L., l.c.): 22 parts Na,SO, 10aq are dissolved in 10 parts water, the solution is heated to boiling, and the flask is then closed with a cork carrying two narrow tubes bent at right angles; when the liquid is cold the outer end of one of the tubes is dipped into 30 p.c. alcohol at 40°, and the alcohol is caused to run into and fill the flask by sucking at the outer end of the other tube. As the alcohol withdraws water, large, translucent, rhombic or tetragonal crystals of Na2SO. 7aq gradually separate. The crystals must be quickly pressed between filter paper.
They rapidly absorb water from the air, changing to Na₂SO₄, 10aq; exposed to air, even under dilute alcohol, they soon change to the decahydrate. According to Löwel (l.c.) the heptahydrate is much more soluble in water between nydrate is much more solubrate. The temperature of maximum solubility is 27°; the solution then contains 56 p.c. Na₂SO₄, which is the same quantity as is present in solution of Na SO. 10aq saturated at 34°-36°. If a crystal of Na, SO, .7aq is added to the saturated solution of this salt at 27° it does not dissolve, but crystals of Na SO. separate until a concentration is reached corresponding with a saturated solution of Na2SO4 at the temperature. The heptahydrate is able form supersaturated solutions, but less readily than the decahydrate; addition of a crystal of Na₂SO, 7aq causes separation of the heptahydrate. These results were confirmed by de Coppet (Bl. [2] 17, 146).

(2) The decahydrate Na. SO., 10aq crystallises from a hot saturated solution of Na. SO, cooled to at least 32°; a supersaturated solution may be cooled in a closed vessel to 0°. If a crystal of Na. SO., 10aq is dropped in, a mass of crystals of the decahydrate is formed, and the temperature rises to c. 18°. Large, white, striated, monoclinic prisms; isomorphous with Na. CrO., 10aq and Na. SeO., 10aq. S.G. 1.469 (Playfair a. Joule, C. S. Mem. 2, 401); 1.485 at 19°, 1.492 at 20° (Pettersson, Upsala, Nova Acta, 1874). [Na. S.O., 10H°O] = 347,800 (Th. 3, 516). Melts at 34° (Tilden, C. J. 45, 267). Effloresces in air. When melted in the water of crystallisation, boiled, and allowed to cool in a closed vessel, Na. SO, separates, but on shaking, this salt dissolves till 18° is reached, after which crystals of Na. SO, 7aq separate (v. supps). Na. SO, 10aq is insol. absolute alcohol; shooth of S.G. *776 dissinsol. absolute alcohol; alcohol of S.G. *776 d

solves 14:85 p.c., of S.G. 972 dissolves 5:6 p.c. and of S.G. 939 dissolves 1.8 p.c. Solubility in water increases with temperature to 33°-34°. whereat the solution contains 55 parts Na₂SO₄ in 100 of water; a crystal of Na₂SO₄.10aq dropped into the solution dissolves, and Na₂SO₄ separates till 49:53 parts Na,SO, are in solution in 100 parts water, which is the same quantity in 100 parts water, which is the same quantity of Na,SO, as is present in a solution made by saturating water with Na,SO, at 34° (Lowel, A. Ch. [3] 83, 334; 49, 82). As temperature is increased above 34° Na,SO, seems to be formed, and the solubility of this salt decreases as temperature rises to the b.p. of saturated Na.SO.Aq. There appear to be three temperatures of maximum solubility for Na2SO, and its hydrates: (1) at 34°, which is the maximum for Na, SO, 10aq, (2) at 26°-27° for Na, SO, 7aq, (3) at 17°-18° for Na, SO,. The quantity of salt in solution, calculated as Na, SO, is about the same at these temperatures. Löwel (l.c.) gives the following

8.G. 1·1015	P.c. Na.80. 11:025	P.o. Na_80. 10aq 25
1.1057	11.466	26
1.1100	11.907	27
1.1142	12.348	28
1.1184	12.789	29
1.1226	13.230	* 80

Acid salts. (1) NaHSO,; by adding 7 parts H₂SO,Aq S.G. 185, to 10 parts Na₂SO,, and heating gently till the mass melts and watervapour ceases to be given off. By dissolving in water, or by evaporating Na₂SO₄ in H₂SO₄at 50°, crystals of NaHSO₄ aq are obtained (Mitscherlich, P. 12, 138; H. Rose, P. 82, 545). (Mitscherlich, P. 12, 138; H. Rose, P. 82, 545). (2) Na,SO, NaHSO, (= Na,H(SO,)2); by crystallising Na,SO, from half as much H,SO, in water as is required to form NaHSO, (M., Lc.; R., Lc.). (3) NaHSO, H,SO, (NaH,(SO,)2); by crystallising Na,SO, from solution in almost 7 parts H,SO, (Schultz-Sellack, J. pr. [2] 2, 459; Lescœur, C. R. 78, 1044).

Double salts. (1) Na, SO, K, SO, (Penny, P. M.

100 parts water contain, when solution is saturated.

The following table gives S.G. of Na,SO,Aq [4] 10, 401; Mitscherlich, P. 58, 468; von 19°:—

S.G. P.O. Na,SO, 10aq 1.0040 1.441 1.0079 1.881 2 with Li,SO, (Raumnelsberg, P. 128, 311; Wyrou-10118 1.323 3 boff, Bi. [2] 9, 35. (4) With sulphates of Cd, Ca, Cu, Di, In, Fe, La, Mn, and Mg; references 1.0108 under Cadmium sulphates, Calcium sulphates, &c. (5) The compounds Na SO, M2 (804) . 24aq, where M = Alor Cr, are alums (references under ALUMINIUM SULPHATES and CHROMIUM SULPHATES). Strontium sulphates. The normal salt SrSO, occurs native as celestine. It is obtained by adding H SO, Aq or solution of an alkali sulphate to solution of a strontium salt; large conc. H₂SO₄, adding dilute HClAq, heating to 150°, allowing to cool, again heating to 150° with HClAq, and repeating this treatment three or four times (Bourgeois, C. R. 105, 1072). SrSO₄ or four times (Bourgeois, C. R. 10s, 1072). SrSO, is also obtained crystalline by fusing K.SO, with excess of SrCl₂ (Manross, A. 82, 350). A white solid; S.G. 3-927 to 3-955 crystalline (M., l.c.; Neumann, P. 23, 1); 3-7 ppd. (Schröder, P. 106, 226; v. also Clarke's Table of Spec. Gravs. [New Ed.] 82). H.F. [Sr,S,O.] = 830,900 (Th. 8, 516). Almost insol. water; S. 0145

ordinary temperature, '0104 at 100° (Fresenius); taking care that Sn is in excess, dissolving the insol. dilute H_SO₄Aq; S. conc. H₂SO₄ at 70° = 14 white solid so formed in water, and allowing to NaCl, KCl, MgCl, and CaCl, v. Virck (C. C. 1862, 402). Melts when strongly heated; is de-(Bousingault, J. 1867, 161). Reduced by heating strongly with C, Fe, or Zn (d'Heureuse, P. 75, 277), or in a steam of H or moist CO (Jac-75, 271), of in a seeam of it of moise to concurrent, C. R. 46, 1164). Loses SO, when heated with As,O₃ (Moretti, S. 9, 169), or when heated continuously to redness in HCl (Bousingault, C. R. 78, 593). Decomposed by heating with solutions of alkali carbonates. Forms double salts, SrSO₄M₂SO₄, with alkali sulphates (H. Rose, P. 93, 604; 110, 296). An acid salt SrH₂(SO₄)₂ (= SrSO₄H₂SO₄) is formed by digesting SrSO₄ in conc. H₂SO₄ with excess of SrSO₄ (Schultz, P. 118, 147).

Thallium sulphates. The normal thallous salt Tl₂SO₄ is obtained by dissolving Tl in hot H₂SO₄ or by neutralising H₂SO₄Aq by TlOH or Tl₂CO₃, and evaporating (Crookes, C. N. 24, 38). Forms white rhombic prisms, isomorphous with K-SO, (von Lang, P. M. [4] 25, 348); S.G. 6:77 (Lamy, Bl. [2] 11, 210; v. also Clarke's Table of Spec. Gravs. [new ed.] 79). H.F. [TI; S.O'] = 221,000 (Th. 3, 516). S. 4:74 at 15°, 18:5 at 1000 (Tany, Ia). 100° (Lamy, l.c.). Not decomposed by heating to full redness in absence of air; heated more strongly in air gives Tl2O8, SO2, and O (Carstanjen, J. 1867. 279). Reduced to Tl₂S by heating with KCN. The acid thallous salt TlHSO, 3aq separates from a solution of the normal salt in H₂SO₄Aq after some months. When strongly heated yields Tl₂SO₄ and H₂SO₄ (Carstanjen, l.c.). Double salts, Tl₂SO₄.MSO₄, 6aq, are formed when M = Cu, Fe, Mg, Ni, or Zn (Willm, A. Ch. [4] 9, 5: Werther, Bl. [2] 2, 272). The salt Tl₂SO₄Al₂(SO₄)₃. 24aq is an alum (v. Lamy, Bl. [2] 11, 210). Normal thallic sulphate Tl₄SO₄O₄, 7aq is obtained as thin, white leaflets by dissolving Tl₂O₃.H₂O in fairly conc. H₂SO₄Aq and evaporating. Loses 6aq when heated to 200°, at higher temperatures SO₂ and O are given off and Tl₂SO₄ remains (Strecker, A. 135, 207: separates from a solution of the normal salt in off and Tl₂SO₄ remains (Strecker, A. 135, 207; Crookes, C. N. 8, 243). The double salts Tl₂(SO₄), M₂SO₄ [= TlM(SO₄)₂], where M = K or Na, are described by Strecker (l.c.).

Thorium sulphates. The hydrated normal sulphate Th(SO4)2. xaq is obtained by dissolving ThO, in slight excess of H2SO, Aq, and crystallising at 10°-15°. The anhydrous salt is obtained by heating the hydrated salt to c. 400° (v. Chydenius, P. 119, 43; Delafontaine, A. 131, 100; Cleve, Bl. [2] 21, 115; Demarçay, C. R. 96, 1860). For a full discussion of the conditions of formation, relations, and solubilities of the of formation, relations, and solubilities of the various hydrates of $Th(SO_4)_2$ v. Roozeboom (Z.P.C.5, 198). $Th(SO_3)_2$ has $S.G.4\cdot058$ at $22\cdot8^\circ$ (Clarke, Am. 2, 175); $4\cdot2252$ at 17° (Krüss a. Nilson, B.20, 1675). The S.G. of $Th(SO_4)_2$, 9aq is $2\cdot767$ according to Topsée (Bl.[2], 21, 120). The hydrate Th(SO₁), 9aq is isomorphous (mono-clinic) with U(SO₄), 9aq (Rammelsberg, B. B. 1886. 603). Double salts Th(SO₄), M.SO₄, xaq are known, where M = an alkali metal (Cleve, l.c.; Chydenius, l.c.).

Tin sulphates. The normal stannous salt SnSO, is obtained, in very small white crystals, by dissolving Sn in warm fairly conc. H.SO.Aq,

white solid so formed in water, and allowing to crystallise out of contact with air (Marignac, Ann. M. [5] 15, 221). SnSO, is very sol. water; the solution soon deposits basic salts. The normal stannic salt Sn(SO4)2. 2aq was obtained by Ditte (C. R. 104, 178) by dissolving SnO₂ xaq (ppd. from SnCl₁Aq by alkali) in dilute H₂SO₄Aq and evaporating (v. also Kraskowitz, P. 35, 518). It forms white rhombic leaflets; very sol. water; decomposed by much water with separation of SnO₂. A basic salt SnO(SO₄), aq is said to be formed (Ditte, l.c.) by dissolving the normal salt in H2SO, Aq, warming, adding excess of Sn, and then ether.

Titanium sulphates. Normal titanous sulphate Ti2(SO4)3. Saq is obtained, as violet crystals, by evaporating a solution of Ti in H2SO, Aq; warmed (Glatzel, B. 9, 1833; Ebelmen, J. pr. 42, 76). Normal tilanic sulphate Ti(SO₄)₂, 3aq was obtained by Glatzel (l.c.) by oxidising the titanous salt by HNO₃, adding a drop or two HEADOS SAIL BY INO., BARRING & GROP OF TWO H.SO., Aq. and evaporating; a white, translucent mass. A double salt Ti(SO.)...K.SO., 3aq was obtained by Warren (P. 102, 449), by fusing TiO. with KHSO., treating with cone. H.SO. evaporating, and washing the residue with cold water (v. also Glatzel, l.c.). By dissolving TiO2 water (v. also Giatzei, i.e.). By dissolving 1102 in hot H_SO,Aq, evaporating, drying the residue on a porous tile at 180°, and then heating to c. 350°, Merz (J. pr. 99, 157) obtained the acid salt TiO.SO, as a hard white solid.

Uranium sulphates. Normal uranic sul-

phate U(SO₄)₂. 9aq is obtained, as green monoclinic crystals isomorphous with Th(SO₄)₂. 9aq (Rammelsberg, B. B. 1886. 603), by evaporating a solution of UO₂ in excess of H₂SO₂Aq (R., l.c.; Ebelmen, J. pr. 27, 385). Unchanged in air; slowly loses water of crystallisation when heated; at higher temperatures gives yellow (UO2)SO4, at higher temperatures gives yenow (UU_)SU, and when strongly heated leaves U_0. Heated in H gives UO₂. Easily sol. dilute H_SO₄Aq or HClAq. Decomposed by water, giving basic satts (v. R., l.c.; Athanasesco, C. R. 103, 271). Forms double satts with alkali sulphates (R., l.c.). The uranyl salt (UO.)SO, xaq is obtained, in citron-yellow crystals, by dissolving U,O, in H,SO,Aq with a little HNO,; or by decomposing UO2(NO3)2 by conc. H2SO4, evaporating nearly to dryness, dissolving in water, evaporating to a syrup, and allowing to crystallise slowly (Ebela syrup, and anowing to crystallise slowly (Enermen, A. 56, 230). By evaporating a solution of the hydrated salt in conc. H₂SO₄, Schultz-Sellack obtained the anhydrous salt (UO₂)SO₄ (B. 4, 13). Forms double salts with alkali sulphates (UO.)SO. M.SO. 2aq (Rammelsberg, B. 5, 1005). Vanadium sulphates. Vanadyl sulphate

(VO)SO4. xaq is obtained by heating a solution of V2O, in conc. H2SO, Gerlach (B. 11, 98) prepared several compounds of V2O, and SO, by dissolving V_2O_3 in H_2SO_4 . For more details and descriptions of various salts v. Vanadium Tetrox-

descriptions of the confidence is obtained by dissolving Zn, ZnO, or ZnCO, in dilute H.SO.Aq, evaporating, drying the crystals of ZnSO. 7aq, and gradually heating to c. 280° till water ceases to be given off; it is difficult to drive off every trace of water without decomposing some of the ZnSO, and forming

basic sulphates. Klobb (C. R. 114, 836) obtained ZnSO, in crystals by heating ZnSO, 7aq mixed with excess of (NH₄)₂SO, in a partlymixed with excess of (NH_{d/2}SO₄ in a party-closed crucible, protected from the gases of the flame, till all (NH_{d/2}SO₄ was volatilised. A white solid; S.G. 3:435 at 16° (Pape, P. 120, 367); 3:6235 at 15° (Thorpe a. Watts, C. J. 37, 108). H.F. [Zn,S,O⁴] = 230,100 (Th. 3, 516). Decom-posed to ZnO, SO₂, and O at c. 400° (Bailey, C. J. 51, 681). Heated with charcoal, SO, and CO2 are evolved and ZnO remains; if the temperature is rapidly raised to a white heat, SO, and CO are given off and ZnS is formed. Heating in H produces an oxysulphide of Zn. For solubility in water v. infra. [ZnSO,,Aq] = 9,950 (Th. 3, 516). For compounds of ZnSO, with NH, v. Schindler (Mag. Pharm. 31, 167; 36, 43), Kane (A. Ch. [2] 72, 290), Müller (Z. [2] 5, 250; 6, 96). Hydrated zinc sulphate. Several hydrates are known. The heptahydrate ZnSO, 7aq crystalknown. The heptahyarate Zhou, 'faq drystallises, at ordinary temperatures, in white, right rhombic, prisms, isomorphous with MgSO, '7aq. S.G. 1'964 (Thorpe a. Watts, C. J. 37, 110), H.F. [Zn,S,O',711'O] = 252,700 (Th. 3, 516). Molts at 50° (Tilden, C. J. 45, 267). At 100° loses 6H,O. Poggiale (A. Ch. [3] 8, 467) gives solubility in water as follows:-

	s.			
Temp.	ZnSO. 7aq	ZnSO.		
00	115.22	43.02		
10	138.21	48.36		
20	161.49	53·13		
30	190.90	58.40		
40	224.05	63.52		
50	263.84	68.75		
60	313.48	74.20		
70	369.36	79.25		
80	$442 \cdot 62$	84.60		
90 -	532.02	89.78		
100	653.59	95.03		

Gerlach (Fr. 8, 260) and Schiff (A. 110, 72) give the following data for ZuSO, Aq:-

•			
Gerlach, at 15°	Schiff, at 20.5°	Petge. ZnSO4. 7ac	
1.0288	1.0289	5	
1.0593	1.0588	10

Almost insol. absolute alcohol; 100 parts of a saturated solution in alcohol of 40 p.c. contain 3-48 parts ZnSO, 7aq (Schiff, J. 1861. 87).

Hexahydrate, ZnSO, 6aq; obtained by crystallising ZnSO, 4aq at 40°; S.G. 2·07 (T. a. W., l.c.; v. also Marignac, J. 1855. 389). Penta-

W., L.; v. also Marignac, J. 1855, 389). Penta-hydrate, ZnSO, 5aq; obtained by boiling the finely-powdered heptahydrate with alcohol of S.G. 825; S.G. 2-206 (T. a. W., Lc.; v. also Kühn, J. 1830, 300; Schindler, Mag. Pharm. 81, 167; 36, 43; Pierre, A. Ch. [3] 16, 242). Dihydrate, ZnSO, 2aq; formed by pouring cold saturated ZnSO, Aq into conc. H₂SO, and wash-

ing the pp. with absolute alcohol; S.G. 2958 (T. a. W., L.c.). Monohydrate, ZnSO, aq; obtained by heating ZnSO, 7aq to 100°-110° till it ceases to lose weight; S.G. 3·28 (T. a. W., L.c.; v. also Graham, P. M. [3] 6, 327, 417). An acid salt ZnSO, H.SO, 8aq is described by von Kobell (J. pr. 28, 492). Several basic salts are formed by boiling solutions of ZnSO, 7aq with ZnO or ZnO.H. (v. Schindler, L.c.; Kühn, L.c.; Kane, A. Ch. [2] 72, 290; Reindel, Z. [2] 5, 508; Habermann, M. 5, 432; Athanasesco, C. R. 103, 271).

Double salts are numerous: (1) With alkali

Double salts are numerous: (1) With alkali Double saits are numerous: (1) With alkali sulphates, ZnSO, M2SO, aaq (v. Pierre, Ph. C. 1846. 410; Tobler, A. 95, 193; Graham, P. M. [3] 6, 827, 417; Karsten, B. B. 1841). (2) With CoSO, FeSO, MgSO, NiSO, &c., to form ZnSO, MSO, xaq (v. Rammelsberg, P. 91, 321; Pierre, Lc.; Etard, C. R. 86, 1399; 87, 602).

Zirconium sulphates. The normal sait

Zirconium sulphates. The normal salt Zr(SO₄)₂ is obtained by dissolving ZrO₄ in slightly diluted H₂SO₄, evaporating, and driving off excess of acid at a temperature below red on excess of acid at a temperature below red heat. $Zr(SO_1)_2$ is decomposed by heating to redness, giving ZrO_2 . By concentrating a solu-tion of $Zr(SO_4)_2$ containing some free H₂SO₄, Paykull (B. 6, 1467) obtained crystals of the tetrahydrate Zr(SO4)2. 4aq (confirmed by Weibull, B. 20, 1394).

Basic salts are obtained by digesting a solution of a salt of Zr with saturated K₂SO₄Aq

(c). Berzelius, P. 4, 117; Warren, J. pr. 75, 361).

Double salts with K.SO, are formed by fusing KHSO, and ZrO, (B., Lc.; W., Lc.).

DITHIOPERSULPHATES. Under the name

of sodium dithiopersulphate, Villes (C. R. 106, 851, 1354) described a salt Na₂S₄O₈. 5aq. This salt was said to be obtained by adding to sodium thiosulphate insufficient water to dissolve all the salt, saturating with SO., adding a little more water, again saturating with SO2, keeping the yellow solution at the ordinary temperature for two or three days, passing in SO, as long as it was absorbed, and, after standing a day or two, evaporating in vacuo over H₂SO₄. A mixture of Na₂S₄O₈ and Na₂S₃O₆ was thus obtained; on exposure to air the crystals of Na2S3O, effloresced, and the Na S,O, was then picked out. The salt Na S.O. was described as white, lustrous, rhombic prisms; unchanged in air; melting at c. 125°, and giving off SO₂ at c. 140°, leaving Na₂SO₃ mixed with S. In a later paper (C. R. 108, 402) V. announced that the salt supposed by him to be Na₂S₁O₆ was only hydrated sodium tetra-thionate Na₂S₄O₆.H.O. NITROSOSULPHATES. In 1800 Davy (Re-

searches, chiefly concerning Nitrous Oxyde) noticed that NO was absorbed by a mixture of Na₂SO₃Aq and NaOHAq, a compound being formed which, on addition of an acid, gave off N₁O while Na₂SO₄ remained in solution; he supposed that the NO was reduced to N₂O, the Na₂SO₄ being oxidised 'o Na₂SO₄ and that the N₂O combined with the NaOH. Pelouze (A. Ch. [2] 60, 151) found that a salt containing N, S, and O was formed in the reaction examined by Davy; to this salt he gave the composition Na, SO, (NO),

A mixture of 1 vol. SO₂ and 3 vols. NO is gradually absorbed by cono. KOHAq or NaOHAq, forming K₂(NO)₂SO₃ or Na₂(NO)₂SO₃.

Ammonium witroscoulphate (NH₄)₂(NO)₂SO₂ is best prepared by passing NO for some hours into cold conc. (NH₄)₂SO₂Aq mixed with 5 to 6 times its volume of NH₄Aq. White crystals of the self-with the cold self-with the cold self-with the selfthe salt gradually form; they are washed with ice-cold NH,Aq, dried in vacuo, and kept in a well-stoppered bottle (Pelouze, l.c.). Potassium nitrososulphate and sodium nitrososulphate, M2(NO)2SO, are prepared similarly to the ammonium salt. Barium and lead nitrososulphates are obtained by ppg. aqueous solutions of the K salt by conc. BaOAq and solution of basic acetate of lead, respectively (Divers a. Haga, C. J. 47, 364). The nitrososulphates readily decompose; they are stable in solution only in presence of excess of alkali. Heated moist they give off N₂O, leaving pure sulphate; heated dry they give NO and sulphite (v. D. a. H., C. J. 47, 208). With acids, and also with most metallic salts in solution, also in contact with spongy Pt, charcoal, Ag₂O, MnO₂, &c., they give N₂O and sulphates. Solution of an alkali nitrososulphate has no reaction with KMnO, Aq (D. a. H., l.c. p. 205). An alkaline solution of the K or Na salt is slowly reduced by Na amalgam, giving K₂SO₂Aq and K₂N₂O₂Aq, or the corresponding Na salts (D. a. H., *l.c.* p. 203).

PERSULPHATES. Pérsulphuric dride S2O, is formed at the anode during the electrolysis of fairly conc. H.SO, Aq (v. Sulphuric peroxide, under Sulphur oxides, p. 616). The acid corresponding with this oxide would be H₂S₂O₈ or HSO₄; this acid has not been isolated, but some of its salts have been prepared

by Marshall (C. J. 59, 771 [1891]).

Potassium persulphate K₂S₂O₈ is obtained by passing a current of 3 to 31 ampères, for some days, through saturated KHSO Aq contained in a Pt dish, wherein is suspended a porous cell containing dilute H₂SO₄Aq; the Pt dish stands in a vessel of copper, through which runs a stream of cold water, and which is connected with the battery so that the Pt dish becomes the anode; the cathode consists of a stout wire of Pt dipping into the dilute H2SO4Aq in the porous cell (for description, and diagram, of the apparatus v. Marshall, C. J. 59, 765-6). The granular salt that slowly separates during electrolysis is collected by filtering through Pt foil, dried on a porous plate, treated with hot water so as to obtain a nearly saturated solution, which is at once rapidly cooled (the mother-liquor yields more K₂S₂O₈ when again electrolysed). K₂S₂O₈ forms small, white, prismatic crystals; by spontaneous evaporation of a solution, large, flat tables are obtained, probably asymmetric. Slightly sol. cold water; S. at 0°=1.77; insol. absolute alcohol, hot or cold. Measurements of the electrical conductivities of solutions of the salt indicated the formula KSO,, and not K₂S₂O,; but Bredig (Z. P. C. 12, 230) showed that Marshall's results were based on data, given by Ostwald, which were not quite accurate (the data were afterwards corrected in Ostwald's Lehrbuch [2nd ed.] 2, 730). Bredig's measurements established the formula $K_2S_2O_4$; and this was confirmed by Löwenberg's determinations of the freezing-points and conductivities of solutions of the salt (Chem. Zeitung, 1892, 838). K,S₂O₈Aq very slowly decomposes at the ordinary tempera-ture, giving KHSO, Aq and O; in contact with

zinc, decomposition is still very slow: with a Cu-Zn couple the rate of change is hastened; heating also hastens the reaction. After keeping for some time in a closed bottle a peculiar smell is noticed on opening the bottle, perhaps due to H₂S₂O₆ or S₂O₇; coone is sometimes also given off. Heat decomposes K₂S₂O₆; K₂SO₄ remains and SO₅ and O are given off.; decomposition is marked at a little above 100°, but is not complete or H₂SO₄, much ozone is given off; Cl is evolved when conc. HClAq is used. K₂S₂O₂Aq does not yield pps. of persulphates with solutions of meyield pps. of persulphates with solutions of metallic salts; when pps. are formed they are due to reactions with K.SO.Aq formed by the decomposition of the K.S.O.Aq. Solution of a salt of Ba slowly throws down BaSO.4; the reaction is very slow, even when the solution is boiled. Solution of a salt of Pb also slowly forms PSO.4. when heated with K.S.O.Aq; if alkali is added, PbO, is ppd. AgNO, Aq produces no pp. at once, but after a time black AgO, the solution becoming acid; several other metallic salts in presence of alkali yield pps. of peroxides with K₂S₂O₈Aq, e.g. salts of Co, Cu, Mn, and Ni. KIAq is slowly decomposed by K₂S₂O₈Aq, with separation of I; litmus and turmeric solutions are gradually bleached; paper and cloth become rotten when dipped in K₂S₂O₈Aq. K₄FeCy₆Aq is exidised to K₂FeCy₆Aq, and alcohol yields aldehyde, by warming with K2S2O8Aq.

Anmonium persulphate $(NH_4)_2S_2O_8$. Prepared, similarly to $K_2S_2O_8$, by electrolysing dilute H_2SO_4Aq (c. 1 to 6 by volume) with $(NH_4)_2SO_4$; the salt is purified by cooling by ice a solution saturated at a little above the ordinary temperature. Crystallises in transparent lozengeshaped, apparently mono-symmetric tables. Very

sol. water; S. at 0'=58'2. Reacts similarly to K₂S₂O₄ (cf. Elbs, J. pr. [2] 48, 185). Barium persulphate Ba₂(SO₄), 8aq. Prepared by rubbing in a mortar saturated (NH₂)_SO₂Aq with excess of pure BaO₂H₂—Ba₂(SO₄), goes into solution, and BaSO, also forms—passing a rapid stream of air till most of the NH, set free in the reaction is removed, placing in vacuo over H₂SO₄ till no free NH, remains, passing in CO₄ to remove excess of BaO₂H₂, keeping in vacuo for a short time (to decompose Ba bicarbonate to BaCO₃), filtering from BaSO₄, and BaSO₅, evaporating in vacuo till crystallisation begins (with addition from time to time of a little BaOAq to neutralise H₂S₂O₈ that is set free during evaporation), dissolving the crystals that first separate in as little water as possible, filtering, cooling by ice, and drying the small prismatic crystals that form on a porous plate. crystals of Ba₂(SO₄), Saq gradually become milky from formation of BaSO₄, the change soon spreads, and the crystals crumble to a moist, powdery mass of BaSO₄. Ba₂(SO₄)₄.8aq is very sol. cold water; S. at 0°=52.2. Sol. absolute alcohol; on standing white crystals are deposited,

alconoi; on standing white crystals are deposited, probably Ba₂(SO₂)₄. 2aq.

Lead persulphate Pb₂(SO₄)₄. xaq; x = 4 or 6, probably 6. Obtained by adding a slight excess of H₂SO₄Aq to cone. Ba₂(SO₄)₄Aq, neutralising with PbCO₂, filtering after some time, evaporating in vacuo over H₂SO₄ (removing PbSO₄ from time to time by filtration) till a solid mass is obtained, which is at once divided between filter payer and which is at once dried between filter paper and

placed in vacuo. Pb₁(SO₄), was not obtained quite free from PbSO₄; it decomposes very readily, giving off pungent fumes, that separate

I from KIAq on paper.

Zinc persulphate was obtained, but not pure,
by adding ZnSO, Aq to Ba, (SO,), Aq in the proper proportions, filtering, and evaporating in vacuo over H₂SO₄. The copper salt was also obtained, but not free from CuSO₄. For thermal data concerning the formation and solution of the persulphates of NH, Ba, K, and Na v. Berthelot

(C. R. 114, 875; abstract in C. J. 62, 931). PYROSULPHATES. (Disulphates. Anhydrosulphates.) Salts of the acid H₂S₂O₂ (v. Pyrosulphuric acid, under Sulphuric acid, p. 620). These salts bear to the sulphates a relation similar to that of the dichromates to the chromates. The sulphates may be written SO₂(OM)₂, and the pyrosulphates OM.SO₂.O.SO₂.OM. The sulphates and pyrosulphates may also be regarded as compounds of the acidic radicle SO, with basic radicles MO; thus sulphates MO.SO,, pyrosulphates MO.SO,. Inasmuch as H.S.O, may be regarded as a partial anhydride of H.SO.(2H.SO., -H.O. = H.S.O.), the acid H.S.O. is sometimes called anhydrosulphuric (cf. ACIDS, vol. i. p. 50).

Potassium pyrosulphate K₂S₂O, is formed by heating K₂SO, with half its weight of H₂SO, till acid ceases to confe off at an incipient red heat. Prismatic needles; S.G. 2.277 (Jacquelain, A. Ch. [2] 70, 311). Melts at 300°, according to Schultz-Sellack (B.4, 109). Cannot be crystallised Schultz-Sellack (B. 4, 109). Cannot be crystallised from water. Solution in fuming H₂SO₄ gives crystals of the acid salt KHS₂O₃, melting at 168° (S.-S., l.c.). Heated with alcoholic solution of KSH gives K₂SO₄, K₂S₂O₃, and H₂S; boiled with C₂H₃ONa in alcohol gives KNaSO₄ and KEtSO₄ (Drechsel, J. pr. [2] 5, 367). The pyrosulphates of NH₄, Ba, Ag, and Na are prepared similarly to K₂S₂O₃ (v. Schulze, B. 17, 2707; J., Lc.; S. S., l.c.). M. M. P. M. l.c.; S.-S., l.c.). M. SULPHAZIDES X.NH.NH.SO₂.Y. M. M. P. M.

Formation .- 1. By the action of alcoholic SO₂ upon diazo-compounds.-2. By the action, of hydrazines upon sulphonic chlorides Y.SO.Cl. 8. By the action of hydrazine hydrochlorides upon sulphinic acids Y.SO.H.-4. By reduction of the compounds X.N. SO.Y.

Reaction .- By heating with aqueous alkalis salphinic acid, a hydrocarbon, and nitrogen:

X.N.H., SO. Y = XH + Y.SO. H + N.

SULPHAZOTISED ACIDS v. SULPHUB OXY-ACIDS, NITROGEN DERIVATIVES OF (p. 619).

SULPHIDES. Binary compounds of sulphur. The name is generally applied only to binary compounds of S with elements less negative than itself-that is, to compounds with elements other than Br, Cl, F, I, or O; thus SO, and SO, are called oxides of sulphur rather than sulphides of oxygen. Compounds of S with organic radicles, which compounds react similarly to sulphides of metals, must be regarded as binary compounds if the definition of the term sulphide is to be made as wide as possible. In the present article, however, only binary compounds of S with less pegative elements are included. Sulphides of

all the metals, and also of the non-metals H. B.

C, N, Si, P, Se, and Te, are known.

Many sulphides of metals occur native. Sulphides are frequently prepared by the direct union of the elements; sometimes by heating metallic oxides with excess of S, e.g. As, S, -in many cases a mixture of sulphide and oxide is formed in this way; addition of alkali carbonate to the mixture of metallic oxide and S sometimes brings about formation of sulphides, e.g. formation of sulphides of Cr and U; polysulphides mixed with sulphates are produced by heating the hydroxides or carbonates of alkali metals with S. Most heavy metals give sulphides when their oxides are heated in H,S gas, also when H2S is passed into solutions of their salts. Heating metals in H2S gas often produces sulphides. Sulphides are also formed by heating one metal with the sulphide of another, more negative, metal. Reduction of sulphates, generally by heating in H or with C, frequently yields sulphides. Some metallic oxides yield sulphides . when strongly heated in vapour of CS2. Sulphides of many heavy metals are formed by immersing the metals in (NH₄)₂SAq containing excess of S (v. Priwoznik, A. 16A, 46). Many metallic oxides yield sulphides by heating with dry Na₂S₂O₃ (v. Landauer, Fr. 1872, 427). The sulphides of the alkali and alkaline earth

metals are soluble in water; other sulphides are insoluble, or only very slightly soluble, in water.

Very dilute aqueous solutions of several metallic sulphides, in the colloidal form, were obtained by Winssinger (BL [2] 49, 452) by the following methods: (1) ppg. the sulphide by H.S from an extremely dilute solution, and dialysing; (2) washing the ppd. sulphide for a long time with cold water, or with dilute H₂SAq; (3) forming the sulphide in a solution free from all substances capable of causing coagulation. In these ways W. obtained colloidal soluble sulphides of Bi, Co, Au, Fe, In, Pb, Hg, Mo, Ni, Pd, Pt, Ag, Tl, W, and Zn. For preparation of colloidal soluble CdS v. Prost (C. C. 1888. 32), and of colloidal soluble CuS v. Spring a. de Boeck (Bl. [2] 48, 165).

Metallic sulphides are decomposed by strong acids, giving salts and H₂S; secondary reac-tions frequently occur, S almost invariably separating. Several sulphides, e.g. Aa₂S, and H₂S, are sublimable out of contact with air; all sulphides are oxidised by heating to redness in air. The sulphides of the very positive metals yield sulphates, and the sulphides of the heavy metals generally form oxides (the sulphides of Au, Hg. Pt, and Ag form metal) and give off SO.. All sulphides of metals yield metallic chlorides and S.Cl. when heated in a stream of Cl. Many metallic sulphides are decomposed by water, at different temperatures, giving oxides or hydroxides and H₂S (cf. de Clermont a. Frommel, C. R. 87, 330). Sulphides of non-metals are decomposed by water, generally to oxyacids and H₂S; NS gives NH, salts of H₂S₂O₄ and H₂S₂O₆. Many sulphides of heavy metals are H₂S₂O₅. Many surprises of next means and decomposed by heating with water and I, giving iodides, S, and a little sulphate (v. Filhol a. Mellies, A. Ch. [4] 22, 58).

The double sulphides, formed by the union of sulphides of more positive elements with sulphides.

phides of less positive elements, are comparable

with the double oxides or oxysalts; most of these double sulphides are probably best regarded as salts of thio-acids corresponding with salts of oxyacids, but it is customary to apply this conception generally only to those compounds which contain sulphides of non-metals or of Sb, As, or Sn. The double sulphides, or thio- salts, are generally decomposed by water, forming oxides and H2S. Many double sulphides, containing K2S or Na2S as one constituent, are formed by fusing metals or metallic sulphates with K₂CO₃, or Na₂CO₃, and S (v. Schneider, J. pr. [2] 7, 214; 9, 209; 10, 55). The sulphides may be classified, like the oxides, as monosulphides, disulphides, &c. It is better, however, to divide them into basic, acidic, indifferent, and persulphides; but this classification has been less developed and applied than in the case of the oxides. Basic sulphides react with acids to form salts and H.S. just as basic oxides react with acids to form salts and H.O. Acidic sulphides react with the basic sulphides to form thio- salts, as acidic oxides react with basic oxides to form oxy- salts; but few compounds have been isolated of acidic sulphides with H.S. corresponding with the compounds of acidic oxides with water which are oxyacids. The more strongly acidic sulphides -that is, the sulphides of non-metals—are decomposed by water, generally giving H2S and oxyacids. The persulphides have not been much studied; any sulphide of an element containing more S than the basic or acidic sulphide of the same element may be placed provisionally among the persulphides. A sulphide which does not react as basic or acidic, and which from its composition cannot well be called a persulphide, may be classed as an indifferent sulphide. The sulphides of C and P combine with several metallic sulphides to form thio- salts; double sulphides (or thio- salts) have not been isolated containing sulphides of B. N. Si, Se, or Te; the sulphides of Sb, As, and Sn combine with the sulphides of the alkali metals, and with some other sulphides of positive metals, to form thio- salts. The greater number of the double sulphides are formed by the union of two sulphides, both of which are metallic. The sulphide of that metal which, on the whole, is the more positive is regarded as the basic radicle; and the sulphide of the metal which, on the whole, is the less positive is regarded as the acidic radicle of the double sulphide. Some metallic sulphides must be classed both as basic and acidic; Cu.S, for example, combines with As.S., and is therefore basic towards the distinctly acidic sulphide of As, but it also combines with K2S, and is therefore acidic towards the distinctly basic sulphide of K. It is impossible to divide the metallic sulphides into two distinctly-marked classes; the relativity of the terms 'basic' and 'acidic' becomes even more apparent in dealing with sulphides than in dealing with oxides. The sulphides BaS, BaS, CaS, and CaS, may be taken as examples of those which are loosely put together under the name persul-phides. As examples of indifferent sulphides NS and Cr.S. may be mentioned. Many metallic sulphides which have been little studied—and which must, therefore, for a time be called indifferentwe very probably basic in their reactions; such we Al, S, and CdS.

M. M. P. M.

SULPHIDO-DIACETIC ACID C.H.SO. 44. S(CH2.CO2.H)2. Thiodiglycollic acid. [129° 42 at 18°. Formed from chloro-acetic acid and alcoholic ammonium sulphide, aqueous Ca(SH), or Na₂S (Schulze, Z. 1865, 73; 1866, 184; Schreiber, J. pr. [2] 13, 472; Lovén, B. 17, 2818). Formed also by heating bromo-acetic acid with benzyl sulphide, allyl sulphide, or ethylene sulphide (Letts, Tr. E. 28, 612). Trimetric tables, v. sol. alcohol. Oxidised by KMnO₄ to SO₂(CH₂SO₂H)₂. The Na salt is converted by treatment with sodium chloro-acetate into $CO_2H.CH_2SMe < {}^{O}_{CH_2}>CO$ [150°] (Delisle, B. 25, 2450). The analogous compound (CO₂H.CH₂)₂S CO₁CO [158°] is formed from chloro-acetic acid, Na₂CO₃, and Na₂S (Delisle), and yields Na₂A" 3aq.

Salts.—K₂A" aq: deliquescent prisms.—

Methyl ether Me.A". (135° at 11 mm.). Ethyl ether Et.A". (268° cor.). Formed from chloroacetic ether and alcoholic KSH (Wislicenus, A. 146, 153).

Amide S(CH, CO.NH,), Formed chloro-acetic acid and alcoholic (NH,).S.

Formed from

Amic acid S(CH2.CO2H).CH2.CO.NH2. [125°]. Prisms, m. sol. cold water. - BaA', aq. CaA'2 aq. - AgA': needles (from hot water).

Imide S CH, CO NH. [128°]. Formed by heating the ammonium salt at 200°. Crystals.

Anhydride S < CH_...CO > 0. [102°]. (158° at 10 mm.). Formed by boiling the acid with AcCl

(Anschütz, A. 273, 68). Needles (from CHCl₂). Chloride S(CH₂COCl)₂. Mono-anilide Š(CH₂CO₂H).CH₂CONHPh.

[103°].

Di-anilide S(CH_CO.NHPh), [168°].

p-Toluide S(CH_CO_H).CH_CO.NHC,H,.

[95°]. Needles.

Di-sulphido-di-acetic acid (di-thio-di-glycollic acid) S₂(CH₂,CO₂H), [100° uncor.]. Formed from thio-glycollic acid CH₂(SH).CO₂H by Fe₂Cl₈ or by atmospheric oxidation of the alkaline solution Glaesson, B. 14, 410; Ginsburg a. Bondzynski, B. 19, 114). White plates or prisms. V. sol. water, alcohol, and ether, sl. sol. benzene. Gives with AgNO, a white pp. AgHA". By tin and HCl it is reduced to thio-glycollic acid.— K,A" 1 aq: easily soluble crystals.—KHA" aq.— BaA" 4aq: amorphous pp. Ethyl ether Et.A".

Ethyl ether Et.A". (c. 280°). Amide [155°]. Crystalline. SULPHIDO DI ACETOACETIC ETHER

C₁H₁SO₂ i.e. S(GHAo.CO₂Et)₂. [90°] (S.); [84°] (D.); [76°] (B.). Formed by the action of S₂O₂ (2 mols.) or of SO₄ on sodium acetoacetter thurs.] (mol.) suspended in benzene (Buohka, B. 18, 2092; 22, 2645, 2555; Delisle, B. 22, 2002). 306). Formed also from cupric acetoacetic ether and S in benzene (Schönbrodt, A. 253, 197). Needles, v. e. sol. benzene. Converted by KOH into sulphido-diacetic acid. Yields a crystalline phenyl-hydrazide C₂₀H₂₂N₂SO₄, converted by warming with an alcoholic solution of phenylhydrazine into oxy-phonyl-methyl-pyrazole-azobenzene NPh.CO C:N.NHPh (Michaelis a.

Phillips, B. 23, 560). Phenyl-hydrazine (2 mols.) added to sulphido-di-acetoacetic ether dissolved in cooled HOAc forms C₂₀H₁₈N₁₈O₂, which yields B'HOAc [161°] and B'HOEt (Michaelis, B. 23, 2476; Sprague, C. J. 59, 332).

SULPHIDO-ANILINE v. DI-AMIDO-DI-PHENYL

BULPHIDE.

DISULPHIDO-DI-BENZOIC ACID

S₂(C₆H₁,CO₂H)₂ [244°]. Formed by oxidation of C₆H₄(SH).CO₂H by moist air or by bromine water (Frerichs, B. 7, 794; Hübner a. Upmann, Z. 1870, 294). Formed also from m-diazo-benzoic acid and H.S (Griess, J. pr. [2] 1, 102) and in actu and 11.3 (Griess, 2. Pr. 12] 1, 102) and, in small quantity, by fusing sodium sulphobenzoate with sodium formate (Ador, B. 4, 622; Meyer, B. 6, 1150). Needles, nearly insol. hot water, st. sol. alcohol. -(NH₃)₂A" 2aq. -CaA" 3aq. -BaA" 3aq. -PbA" aq. -Cu₂(OH)₂A" 5aq. -Aa" 11. Ag₂A" 1 aq: yellowish-white pp.

y-SULPHIDO DIBUTYRIC ACID

S(CH₂.CH₂.CH₂.CO₂H)₂. [99°]. Formed by warming its nitrile with fuming HClAq (Gabriel, B. 23, 2492). Flat crystals.

Nitrile S(CH, CH, CH, CN), (above 300°). Formed by boiling γ-chloro-butyronitrile with alcoholic K₂S. Thick liquid.

a-Sulphido-dibutyric acid S(CHEt.CO.H)... a-supplied odistryine acid SIGHELUO, ILI,... [105°]. Formed by heating a-bromo-butyric ether (2 mols.) with an alcoholic solution of KSH (1 mol.) and KOH (1 mol.), and saponifying the product (Lovén, J. pr. [2] 33, 102). Tufts of needles (from water).—Bah".

-Sulphido-di-isobutyric acid SICMc₂-CO,H).

Formed from a-bromo-isobutyric ether and alcoholic K.S, the product being saponified. Tablets (from water), insol. dilute H.SO. -BaA" 2aq.

Di-γ-sulphido-dibutyric acid S₂(CH₂CH₂CH₂CO₂H)₂. [109°]. Formed by boiling the amide with conc. HClAq (Gabriel). Flat plates, v. sol. alkalis.

Amide S₂(C₃H₆.CO.NH₂)₂. [167°]. Formed by dissolving Cy.C₂H₈.S.Cy in cold conc. H₂SO₄.

sulphilo-dicinnamic acid C₁₈H₁₈SO₄
i.e. (PhCH:C(CO₂H))₂S. Formed by boiling sulphido-diacetic acid with Ac₂O and NaOAc (Loven, B. 18, 3242). Small needles (from alcohol) incl. hol), insol. water. Yields $C_{18}H_{14}Br_2SO_4$.—
Na,A''2\sqrt_aq: silvery plates.
Di-a-sulphido-di-cinnamio acid $C_{22}H_{12}S_2O_4$ Yields C18H14Br2SO4-

t.e. (Ph.CH.C.CO.H),S, [179°]. Formed by the oxidation of sulphydro-cinnamic acid Ph.CH.C(SH).CO₂H by iodine in alcoholic solution. Long yellowish needles, v. sol. alcohol, less in benzene (Ginsburg a. Bondzynski, B. 19, 123).

DI-SULPHIDO-DI-METHENYL-DI-AMIDO-DI-NAPHTHYL MERCAPTAN

 $S_2(C \stackrel{N}{\leqslant}_S) C_{10}H_s)_2$. Formed by oxidation of C₁₀H₆<NSC.SH with alkaline K₂FeCy₆ (Jacobson a. Frankenbacher, B. 24, 1408). The (a)-compound melts at 194°, the (β) - isomeride at 180°.

DISULPHIDO - DI - METHENYL-DI-AMIDO -DI-PHENYL MERCAPTAN $S_2(O \triangleleft_{S}^N > C_uH_4)_2$. [186°]. Formed by oxidising sulphydro-methenylamido phenyl mercaptan with K₂Cr₂O, and HOAc Jacobson a. Frankenbacher, B. 24, 1404; cf. Hofmann, B. 20, 1789). Plates (from benzene).

DI - SULPHIDO - DI . METHENYL . DI . BENZENYL - DI - AMIDOSULPHIM

 $S_2(C \stackrel{N}{\leqslant}_{S.N}) > CPh)_r$ [120°]. Formed by oxidation of $C_{\epsilon}H_{s}.C \leqslant_{N,S}^{N} > C.SH$ (Crayen, B. 24, 389). Stellate groups of needles, insol. water, sl. sol. alcohol. Reduced by sodium amalgam to the parent substance.

DI - SULPHIDO - DI - METHENYL - DI - p -TOLENYL-DI-AMIDOSULPHIM

 $S_2(C \leqslant_{S,N}^N \geqslant C.C_6H_4Me)_2$. [169°]. Formed by oxidation of C,H,.C \$\left(\backslash\) N.S \$\right(C.SH)\$ with HNO. free from nitrous acid (Crayen, B. 24, 392). Needles, insol. alcohol and ether, sol. hot C₈H_e.

DI-SULPHIDO-DI-METHYL-ANILINE v. TETRA-METHYL-DI-AMIDO-DI-PHENYL-DI-SULPHIDE.

DI - SULPHIDO-DI-NAPHTHALENE-DI-(B). SULPHONIC ACID $S_2(C_{10}H_{10}SO_1H)_2$. Formed from the product of the action of potassium xanthate on diazotised (β) -naphthylamine (β) sulphonic acid by treatment with alcoholic potash (Leuckart, J. pr. [2] 41, 223). Colourless plates, v. sol. water and alcohol. Reduced by zinc-dust and dilute H.SO, to C10Ha(SH).SO3H. K2A".-PbA": amorphous pp., sl. sol. water.

SULPHIDO-DI-(B)-NAPHTHYL-CARBAMIC ACID. Phenyl ether

SC_{0,H} N.CO.OPh. [215]. S. (96 p.c. alco-hol) 20 at 16°; S. (benzene) 1.20 at 16°, hol) 20 at 16°; S. (benzene) 1.20 at 16°, Formed from the chloride and alcoholic NaOPh

Portner from the emotion and accounts that in (Paschkowszky, B. 24, 2916). Needles.

Chloride S:(C₁₀H_{all}:N.COCI. [255°].

Formed by heating β-imido-di-naphthyl sulphide with COCl₂ in toluene at 170°. Needles (from the country of the countr benzene-alcohol), v. sl. sol. ether. Converted by aniline into S:(C₁₀H_a)₂:N.CO.NHPh, which is crystalline, S. (96 p.c. alcohol) 04; S. (benzene) 18 at 17.5°, converted by boiling aniline into $S(C_{10}H_8NH_2)_2$ and $CO(NHPh)_2$. The chloride is converted by alcoholic NH, at 145° into $S < C_{10}^{C_{10}H_6} > N.CO.NH_2$, crystallising in needles, S (96 p.c. alcohol) ·06; S. (benzene) ·10 at 17·5°. The chloride $S < {C_{10}H_u} \choose {C_{10}H_u} N$.COCl is converted by β -imido-di-naphthyl sulphide in xylene at 280° into $\left(S < {C_{10}H_u} \choose {C_{10}H_u} N\right)$.CO, crystallising in

yellowish plates and tables [over 350°]. SULPHIDO-DI-PHENYL-AMINE v. IMIDO-DI-PHENYL SULPHIDE

SULPHIDO-DI-PHENYL-CARBAMIC ACID. Ethylether SC.H. N.CO.Et. [110].

Formed from imido-di-phenyl-sulphide and CICO_Et (Fränckel, B. 19, 1845). Silky plates.

Phenyl ether S:(O₄H₄),:N.CO₂Ph. [164°], S. (96 p.c. alcohol) '24 at 16°; S. (benzene) 1.9 at 16°. Formed by heating the chloride with NaOPh in alcohol on the water-bath (Paschkowzky, B. 24, 2908). Needles.

Chloride S:(O₄H₄):N.COCl. [172°]. Formed from S:(O₄H₄):NH and COCl₂ at 100°. Colour-less prigms, sol. objectory and hot HOAs.

less prisms, sol. chloroform, and hot HOAc.

p-SULPHIDO-DI-PHENYL-DI-HYDRAZINE p-SULPHIBU-Da-Fills.

S(O,H,NH.NH₂), [116°]. Formed from S(O,H,NH₂), by diazotisation, treatment with NaHSO, and reduction with zinc-dust (Ruhl, B. 23, 3482; A. 270, 149). Yellowish leaflets, decomposing at 130°, sl. sol. cold water and alcohol. Reduces Fehling's solution in the cold. Benzoic aldehyde yields S(C,H,.N,H:CHPh), — B"2HCl. B"H,SO, [219°].—B"H,C,O,. [209°].

SULPHIDO PHENYL NAPHTHYLAMINE

S C H NH. Imido-phenyl-naphthylamine. Formed by heating phenyl-naphthyl-amine with 8 at 240° (Kym, B. 23, 2464). The (a)-compound melts at 138°, the (B)-isomeride at 178°. Both form yellow crystals, m. sol. hot alcohol, and give a deep blue solution in conc. H2SO1.

SULPHIDO . DI . PHENYL . DI . (B) . NAPH . THYL-UREA N(C₁₀H₁)₂.CO.N C₀H₁ S. [225°]. S. (96 p.c. alcohol) ·12; S. (benzene) ·55 at 16°, at 260° (Paschkowezky, B. 24, 2914). White nodules, al. gol. hot alcohol, sol. hot benzene.

Sulphido - tri - phenyl - (8) - naphthyl - urea NPh(C_{1e}H₁).CO.N:(C₆H₁)₂:S. [170°]. S. (96 p.c. alcohol) 52; S. (benzene) 3·38 at 15°. Formed by heating sulphido-di-phenyl-carbamic chloride with phenyl-(\$\beta\$)-naphthylamine at 250° (P.).

SULPHIDO - DI - PHENYL - DI - TOLYL - DI-GUANIDINE (NHPh.C(NH).NH.O,H_u)₂S. [153°]. Formed from the corresponding thio-urea, HgO, and alcoholic NH, (Truhlar, B. 20, 675). Needles

(from ether ligroin). — $C_{28}H_{28}SN_3H_2PiCl_3$.

Sulphido-tetra-phenyl-di-tolyl-di-guanidine (NHPh.C(NPh).NH.C,H₀)₂S. [106°]. Formed by warming an alcoholic solution of (NHPh.CS.NHC,H₆)₂S with aniline and HgO.

Grey amorphous powder, v. e. sol. alcohol. Disulphido-di-phenyl-tetra-tolyl-di-guani-dine NPh:C NH.C.H.S.C.H., NH C.NPh.

[119°]. Formed by heating the corresponding thio-ures with excess of aniline and HgO. Resinous mass, v. e. sol. alcohol.

SULPHIDO - DI - PHENYL - DI . TOLYL . DI-THIO.DI.UREA (NHPh.CS.NH.C.H.,)2S. [134°].
Formed from S(C,H.,NH.), and phenyl-thio-carbimide (Truhlar, B. 20, 670). Needles.

SULPHIDO-DI-PHENYL-UREA C13H10N2SO i.e. S < N.CO.NH₂. [202°]. S. (96 p.c. alcohol at 17.5°) 3; S. (benzene) 2.7 at 17.5°. Formed from S:(C₆H), N.COCl and alcoholic NH, (Paschkowezky, B. 24, 2908), Plates.

Sulphido-tri-phenyl-urea SCO.H. N.CO.NHPh. [169°]. S. (96 p.c. alcohol) 26 at 17.5°; S. (benzene) 3.74 at 17.5°. Formed from S(C₆H₁)₂NCOCl and aniline. Bluish needles, sol. alcohol.

Sulphido-tetra-phenyl-urea S(C,H,),N.CO.NPh. Formed in like manner, using NPh,H. Hexagonal plates.

Di-sulphido-tetra-phenyl-urea $OO(N < \stackrel{\circ}{O}_{OH} > S)$. [225'] (F.); [231°] (P.). S. (96 p.c. alcohol) 048 at 17°; 4·16 at 78°. by heating NH:(C,H,)2:S with S:(C,H,),:N.COCl (Fränckel, B. 18, 1848). Plates (from HOAc), v. sl. sol, ether and hot alcohol,

DI-SULPHIDO-DI-PROPYL-DI-PHTHAL. AMIC ACID C₂₂H₂₁N₂S₂O₄ i.e. S₁(C₂H₂,NH.CO.C₄H₁,CO₂H)₂. [186°]. Formed by boiling (γ)-phthalimido-propyl sulphocyanide with a 10 p.c. solution of KOH (Gabriel a. Lauer, B. 23, 89). Plates (from HOAc), v. sol. alkalis.—K,A": crystalline pp.

(a) SULPHIDO DIPROPIONIC ACID S(CHMe.CO,H), Thiodilactylic acid. [125]. Formed, together with CH,CH(SH).CO,H, by boiling potassium a-chloro-propionate with KSH (Schacht, A. 129, 4; Böttinger, A. 196, 106). Formed also by passing H_sS into a solution of potassium pyruvate (Böttinger, B. 12, 1425) and by the action of CH₂·CH(SK).CO₂K on CH₂·CHCl.CO₂K (Lovén, *J. pr.* [2] 29, 373). Monoclinic prisms, v. e. sol. water, alcohol, and ether. Not affected by nascent hydrogen. Oxidised by dilute HNO₃ to SO₂(CHMe.CO₂H)₂.

- K.A": deliquescent.—BaA": amorphous, v. sol. water (S.). Its solution on boiling deposits a crystalline salt, S. 1 (L.).—Ag₂A": amorphous

Di-(a)-sulphido-dipropionic acid $S_2(CHMe,CO_2H)_x$ [142°]. Formed by oxidation of CH_3 , CH(SH). CO_2H by I or FeCl. (S.; Böttinger, A. 196, 103; B. 16, 1047; Lovén, J. pr. [2] 29, 372). Needles, sl. sol. cold water, v. sol. alcohol and ether. Reduced by zinc and HClAq to CH₂,OH(SH).CO₂H.—(NH₄)₂A".—K₂A" 2aq.— Ag,A": amorphous pp.

Di-β-sulphido-dipropionic acid S_x(CH_x-CC_x-H_y. Formed by oxidation of CH_x(SH).CH_x-CO_xH (L_x). Thin silvery plates.

Tri-sulphido-di-propionic acid

S₄(CHMe.CO₂H)₂. [95°]. Formed from CH₄.CO.CO₂H and H₂S (Lovén, *J. pr.* [2] 47, 173). Plates, v. sol. hot water. Yields a-sulphopropionic acid on oxidation.

SULPHIDO-TOLUIDINE v. DI-AMIDO-DI-TOLYL SULPHIDE.

SULPHIDO - DI - TOLYL - DI - CARBAMIC ETHER S(C.H.Me.NH.CO.Et). [113°]. Formed from imido-di-tolyl sulphide and ClCO₂Et (Truhlar, B. 20, 668). Needles, v. sol. alcohol.

DI-SULPHIDO TETRA TOLYL-DI-GUANI-DINE C(NH) NH.C,H.,S.C,H.,NH C(NH). [196°]. Formed by botting the corresponding thio-urea with alcoholic NH, and HgO (Truhlar, B. 20, 673). White amorphous powder, v. sol. benzene and hot alcohol. -B'₂H₂PtCl₆: brown

amorphous powder. SULPHIDO-DI-TOLYL-THIO-UREA

 $S<_{C,H,NH}^{C,H,NH}>cs.$ [235°]. Formed from S(C,H₈.NH₂)₂ and alcoholic CS₂. Sulphido-di-tolyl-di-thio-di-urea

S(C,H, NH.CS.NH.). [121°]. Formed by evaporating the hydrochloride of di-amido-di-tolylsulphide with ammonium sulphocyanide (Truhlar, B. 20, 669). Amorphous powder, sl. sol.

Di-sulphido-tetra-tolyl-di-thio-di-urea CS<NH.C,H.,S.C,H.,NH.>CS. [231°]. Formed by boiling an alcoholic solution of di-p-amido-di-tolyl sulphide with CS, (Truhlar, B. 20, 672).

wante amorphous powder, nearly insol, ordinary solvents.

SULPHIDO-DI-TOLYL-DI-UREA

S(C.H.Me.NH.CO.NH.). Formed from amido-di-tolyl sulphide, hydrochloride from and potassium cyanate (Truhlar, B. 20, 669). Crystallises from benzene in needles [1510] contain-

Di-sulphido-tetra-tolyl-di-urea

CO NH.C.H. S.C.H. NH CO. Formed from S(C,H₀,NH₂)₂ and COCl₂ (Truhlar, B. 20, 671). White amorphous powder, sol. hot alcohol. SULPHIDO-DI-ISOVALERIC ACID

S(C₄H₈,CO₂H)₂. Formed from bromo-isovaleric acid and K₂S (Lovén, J. pr. [2] 33, 102). Crystals.

-BaA": in soluble powder.
SULPHIMIDE SO₂.NHAq. Obtained only in aqueous solution, which is prepared by decomposing the Ag derivative, SO₂NAg, with the proper quantity of dilute HClAq, and filtering. The compound SO₂NAg is prepared by saturating well-cooled SO₂Cl₂ in 15-20 vols. CHCl₃, with dry NH₃, dissolving the pp: in water, acidifying with HNQ₃, ppg. all Cl by AgNO₃Aq, filtering, neutralising with KOHAq, and adding more AgNO₃Aq; the pp. thus obtained is purified by recrystallisation from water. The compound SO₂.NAg is also obtained by heating SO₄(NH₂)₂ (p. SULPHAMIDE, p. 567) to 200°-210°, dissolving in water, ppg. by AgNO₃Aq, and recrystallising the pp. from water. The solution in water of SO₂.NH is strongly acid; when dilute it may be helical for a characteristic with the solution of the solution of the solution in water of SO₂.NH is strongly acid; when dilute it may be boiled for a short time without decomposition; NH, HSO, is formed on evaporation, even below 40°; the solution is decomposed by warming with acids, giving H₂SO₄Aq and NH₂Aq; excess of alkali reacts slowly even on boiling (W. Traube, B. 25, 2472; 26, 607). Metallic derivatives of SO₂NH wherein H is replaced by NH., Ba, Ca, Pb, K, Ag, and Na are described by T. (cf. Imido-sulphonic acid and salts, under Sulphonic acids and derivatives, p. 600) M. M. P. M.

SULPHIMIDO-AMIDE SO,NH,NH.NH,SO, Imido-sulphamide. Imido-sulphonamide. Imido-sulphurylamide). Prepared by adding ammonium carbamate very slowly to S.O.Cl. well cooled in a small closed flask, allowing to stand for some time with a CaCl, tube fitted through the cork, then heating to 60° for some hours, washing out NH,Cl by repeated treatment with dry alcohol saturated with NH3, dissolving the residue in a little NH, Aq, and placing the solution in ice. Forms white lustrous crystals; boiling NH, Aq transforms it wholly to ammonium imidosulphonate; with boiting conc. HClAq is completely changed to (NH_d)₂SO₄; when boiled with NaOHAq gives off two-thirds of its Nas NH₃ and forms sodium imidosulphonate (Mente, A. 248, 263). M. M. P. M.

SULPHINDIGOTIC ACID v. INDIGO DI-SUL-

PHONIC ACID.

SULPHINES. Alkyl iodides combine with di-alkyl sulphides forming compounds R2SRI, from which moist Ag₂O produces strong bases R2SR'.OH. In these bases the group (SR2R') may be looked upon as a monovalent basylous radicle derived from the hypothetical sulphine (SH.). Thus Me, SEtI may be called di-methyl-sthyl sulphine iodide, but in this dictionary it

is described as the ethylo-lodide of Di-METHYL SULPHIDE. In the same manner Me, SCI may be called tri-methyl-sulphine chloride, but in this dictionary it is described as the methylo-chloride

of DI-METHYL-SULPHIDE.

SULPHINIC ACIDS. Organic acids containing the group SO(OH) where S is united to carbon. They may be obtained by reducing the chlorides of the sulphonic acids, in alcoholic or ethereal solution, with zinc-dust (Otto, B. 9, 1584). Fatty sulphinic acids are formed by the 1584). Fatty suppliffic acids at communication of SO₂ or of SO₃ on zinc alkyls (Hofmann, A. 102, 72; 106, 287). They are readily oxidised to sulphonic acids. The aromatic sulphinic to sulphonic acids. The aromatic sulphinic ethers are readily oxidised by KMnO, and HOAc to sulphonic ethers (Otto a. Rossing, B. 19, 1224). By zinc and dilute H₂SO, sulphinic acids are reduced to mercaptans. The aromatic sulphinic acids yield K₂SO₃ and hydrocarbons when fused with potash. The alkyl ethers of sulphinic acids X.SO.OR are formed by passing HCl into a solution of the acid in the corresponding alcohol, and also by the action of chlorocarbonic ethers Cl.CO.R upon the sodium sulphinate X.SO.ONa in cold alcohol, CO, being evolved. The ethers are not formed by the action of alkyl halogenides upon sulphinates, for by this reaction the isomeric sulphones X.SO. R are produced instead (Otto a. Rossing, B. 18, 2493). H.S passing through benzene sulphinic ether at 50° forms mercaptan, benzene sulphinio acid, benzene sulphonic acid, and other products. (Otto a. Rossing, B. 20, 2275). COCl, converts sodium benzene sulphinate into the anhydride (Ph.SO)2O, which is v. sol. ether and benzene, and decomposed by water and alcohol into benzene sulphinic acid and ether respectively (Otto, B. 20, 3337).

SULPHITES HYPOSULPHITES. AND SULPHITES are salts of sulphurous acid formed by replacing H in H₂SO₃ by metals. All sulphites may be represented by the formula xMO.ySO2, where MO stands for an equivalent of a metallic oxide; the normal sulphites belong to the forms M₂SO₃, M¹¹SO₃, M¹¹¹₂(SO₃)₃, and M¹¹(SO₃)₂; the greater number of the acidic sulphites are of the forms M'HSO, and M''(HSO,)2, a few which contain more than one equivalent of acidic radicle to one of basic radicle may be represented as M12SO4.xSO2. Double sulphites are fairly numerous.

Many sulphites are prepared by passing SO. into water wherein metallic hydroxides or carbonates are dissolved or suspended; some are formed by double decomposition from the alkali sulphites. Several metallic sulphites that are insoluble in water can be prepared by the reaction between solutions of the sulphates and solution of Na2SO2; two main reactions occur, ap-(1) Muso, Aq + Na, So, Aq = Muso, + Na, So, Aq, (2) Muso, Aq + 2H₂O = MO₂H₂ + H₂SO, Aq, so that normal sulphites are formed in some cases and basic sulphites in other cases. This method of forming sulphites has been examined by Seubert a. Elten (Zeit. f. anorg. Chem. 4, 44): they find that normal sulphites are always formed when M - Ba, Cd, Ca, Fe¹, Pb, Ag, Sr, or Tl (with Hg¹¹ a double sulphite HgSO₂, Na, SO₂, H₂O was formed); that normal sulphites are formed at low temperatures, using the salts in the ratio of equal molecules, when M=Mg, Mn, Sn^n , $U(UO_2)$, or Zn, but that at higher temperatures, or with more dilute solutions, basic sulphites of these metals are produced; and that basic sulphites are always obtained when M = Al, Be,

Bi, Cr, Co, Cu, Fe^{III}, or Ni.

The sulphites of the alkali metals, and the acid sulphites of the alkaline earths, are soluble in water; most other sulphites are insoluble. Sulphites in aqueous solution, and many in moist air, readily oxidise to sulphates; salts of other S oxyacids are sometimes formed, and S is frequently separated (cf. Pierre, C. R. 62, 460; 73, 749). Oxidisers, such as ClAq, HNO, Aq, &c., quickly convert sulphites into sulphates; sulphite solutions are, therefore, energetic reducers. Solutions of sulphites are readily reduced, giving H.S or metallic sulphides, by SnCl.Aq, Zn and HClAq, &c. Heated with C, they are reduced to sulphides, sometimes to oxides. Sulphites decompose at a red heat to sulphides and sulphates, compose at a roa neat to suprinces and sulpnates, or to exides and SO₂. Sulphites are decomposed by almost all acids, not by CO₂Aq of boric acid, giving off SO₂. Solutions of sulphites generally form thiosulphates by reacting with S, H.S or alkali hydrosulphides. Sulphites give sulphates and thiosulphates when heated in SO, (Divers, C. J. 47, 205). Sulphites scarcely react with POCl, according to Divers (l.c.); a little metallic chloride and phosphate are formed, but no SOCl₂. Divers (l.c.; also C. J. 49, 577) contends that the normal sulphites have the constitution SO2OM.M-that is, that they contain the sulphonic group SO₂OM - and that they are not thionyl compounds, SO(OM)2.

Aluminium sulphites. The only salt that has been definitely isolated is the basic sulphite Al₂O₂.SO₂. 4aq; obtained by dissolving freshly ppd. AlO₃H₃ in SO₂Aq, and heating to 74°, when the salt separates as a white powder. Heated in air gives off H.O and SO., and leaves sulphate (Gougginsberg, A. 45, 132; confirmed by Röhrig, J. pr. [2] 37, 217).

Ammonium sulphites. The normal salt (NH₄)₂SO₂, aq was found in the fumes from the residues from gas-works used in the preparation of (NH₄)₂SO₄ (Scheitz, Ar. Ph. [3] 5, 332); it is prepared by adding absolute alcohol to SO, Aq made alkaline by NH, Aq, or by passing moist SO, and moist NH, into absolute alcohol (Muspratt, P. M. [3] 30, 414). White monoclinic leaflets; sol. in 1 part water at 12° with disappearance of heat. Does not deliquesce in air, but oxidises gradually to sulphate (Marignae, Ann. M. [5] 12, 25). The acid salt NH, HSO, is obtained, as very deliquescent rhombic crystals, by saturating a solution of the normal salt with SO₂ and allowing to crystal-lise in vacuo; loses SO₂ at the ordinary temperature; S separates on exposure to light; a saturated solution heated to 150° in a sealed tube decomposes to S, H2SO4Aq, and (NH₁)₂SO₄Aq (Barbaglia a. Gucci, B. 13, 2325). The basic salt 3(NH₄)₂O.2SO₂, 2aq described by Muspratt could not be obtained by Marignac. Double salts are described under the various aulphites.

Barium sulphites. The normal salt BaSO. is prepared by double decomposition from BaCl₂Aq and Na₂SO₃Aq; a white powder, insol. water; may be crystallised in hexagonal forms

from warm saturated SO.Aq; heated in a closed tube decomposes to BaSO, and BaS (Rammels. berg, P. 67, 891). Easily sol. HClAq (Johnson, C. N. 58, 155; cf. Hodges, ibid. 128).

Beryllium sulphites. No salt has been isolated; a solution of a sulphite (? BeSO₂) is obtained by dissolving BeO₂H₂ in SO₂Aq, but crystals do not form on evaporation alone or over H₄SO₄; addition of alcohol causes formation of a thick syrup (Atterberg, Bl. [2] 24, 358; cf. Berthier, A. Ch. [3] 7, 77).

Bismuth sulphites. A basic salt

2Bi₂O₃SO₂. 5aq is formed by the action of conc. SO₂Aq on BiO₃H₄ (Rörrig, J. pr. [2] 37, 217; cf. Muspratt, P. M. [3] 30, 414).

Cadmium sulphites. The normal salt CdSO₃

is obtained by dissolving CdCO, in SO Aq, and crystallising; white, indistinctly crystalline salt; scarcely sol. water; heated gives SO2, CdO, CdS, and CdSO, (Rammelsberg, P. 67, 256). By treating Cd with SO.Aq, filtering from CdS, and concentrating carefully, Fordos a. Gélis obtained the dihydrate CdSO, 2aq; the same salt was obtained by Muspratt (Lc.); confirmed by Röhrig (Lc.). Denigès (BL. [3] 7, 569) failed to obtain this hydrate, but states that a trihydrate is produced by mixing equal vols. of 10 p.o. solutions of CdSO₄ acidified with acetic acid and Na₂SO₃. A double animonium-cadmium sulphite CdSO₃ (NH₄)₂SO₃ was obtained by Rammelsberg (l.c.).

Calcium sulphites. The normal salt CaSO₃.2aq is prepared by ppg. CaCl₂Aq by Na₂SO₃Aq, dissolving in SO₂Aq, and crystalli-The normal salt sing; it forms small lustrous crystals (Muspratt, Lc.). Also obtained by passing SO, into water with CaCO, in suspension (Röhrig, Lc.). Heated to 80° gives 2CaSO, aq and loses all water at 100° (R., Lc.). R. failed to isolate any acid salt.

Chromium sulphites. A basic chromic salt 2Cr.O. 3SO₂. 16aq was obtained by Muspratt (P. M. [3] 30, 414), as a pale-green pp., by adding alcohol to solution of CrO₃H₃ in SO₂Aq; composition confirmed by Röhrig (J. pr. [2] 37, 217). Alkali sulphite solutions do not ppt. solutions of chromic salts even after long boiling (Berthier, A. Ch. [3] 7,77). By adding K₂SO₃Aq to CrCl₂Aq, Moberg (J. 1847-8. 413) obtained a reddish pp. which was perhaps a chromous sul-

Cobalt sulphites. The normal cobaltous salt CoSO₃. 5aq was obtained by Muspratt (l.c.), as a red granular pp., by passing SO2 into water with CoCO, in suspension, boiling out air from the Solution, and letting cool in a closed vessel. By evaporating in H, Rammelsberg (P. 67, 391) obtained the trihydrate; the existence of both hydrates has been confirmed by Röhrig (l.c.). Double salts CoSO₃.K₃SO₃ and 2CoSO₃.Na₂SO₃.CoO were obtained by Schultze (J. 1865. 270) by heating CoSO₃ or CoCl₂ with albeit sulphite solutions. Double salts of alkali sulphite solutions. Double salts of cobaltic sulphite Co. (SO.). M. SO., where M = K or Na, were obtained by Geuther (A. 128, 157) by continued heating of CoO,H, with fresh

quantities of cone. M.SO.Aq.
Copper sulphites. Neither cuprous nor cuprie sulphite has been isolated, but several double salts of cuprous sulphite are known. The green liquid obtained by dissolving CuCO. (Berthier, A. Ch. [3] 7, 86) or CuO.H. (Bettger, A. 89, 178)

in SO.Aq probably contains Cu.SO.; but this solution rapidly decomposes with separation of a red pp. and formation of CuSO Aq. The red solution formed by passing SO, into water with freshly prepared Cu₂SO₂(NH₄)₂SO₂ (v. infra) in solution was supposed to contain Cu.SO, by Bogojski (J. pr. 53, 403); but Péan de Saint-Gilles obtained only Cu.SO₂. CuSO₂. 2aq from this solution (A. Ch. [3] 42, 23), and this was confirmed by Svensson (B. 4, 713).

According to Newbury (Am. 14, 232), a basic cupric sulphite 6CuO.4SO... 3aq is formed by passing SO. into cold water with CuO.H. in suspension, and sending a stream of air into the green solution so formed until a bright-yellow pp. is produced. When this basic salt is boiled with water for a few minutes CuSO, Aq is formed, and a brown pp. is thrown down. The brown pp. is thought by N. to be Cu2SO3; on continued

boiling with water it gives off SO, and Cu,O

remains.

Double cupro-cupric sulphites. The dihydrated salt Cu₂SO₃. CuSO₃. 2aq was obtained by Chevreul (A. Ch. 83, 183) by heating CuO or CuCO₃ with SO₂Aq; it is also prepared by boiling CuSO₄Aq with solution of an alkali sulphite or thiosulphate, by boiling the green double salt Cu2SO3.(NH4)2SO3 (infra) with water (P. de St.-G., I.c.), by passing SO, into conc. Cu(C.H.O.).Aq at 65° till the yellow pp. that forms is dissolved, and then letting stand in air (Étard, C. R. 93, 725), and by passing a slow stream of SO2 into 10 p.c. CuSO, Aq containing a roll of thin sheet Cu till the liquid is almost colourless (the salt deposits on the Cu) (Newbury, Am. 14, 232). Translucent, garnet-red octahedra; S.G. 3.57; gives up 2H₂O, and also SO₂, above 150°, and at a higher temperature leaves Cu2O with some CuSO₄ (Rammelsberg, P. 67, 391). Soluble SO₂Aq, HClAq, and NH₃Aq; KOHAq ppts. hydrates of CuO and Cu₂O; heated with water to 200° gives CuSO, Aq and Cu in crystalline leaflets (Geitner, A. 129, 350). The pentahydrate Cu2SO3. CuSO3. 5aq separates, as a greenish-yellow pp., from conc. Cu(C₂H₃O₂)₂Aq, into which a slow stream of SO₂ has been passed till the liquid has become emerald-green (P. de St.-G., l.c.). Easily sol. SO Aq or acetic acid, also in solutions of cupric salts and in NH, Aq; when boiled with water the red dihydrate is formed.

Double salts of cuprous sulphite with alkali sulphites are readily produced by the reaction of conc. solutions of alkali sulphites with solutions of cupric salts. double salts are colourless and crystalline; their composition is $xCu SO_3 yM_SO_3$, zaq (x generally = 1), where $M = NH_3$, K, or Na (for details of preparation, composition, and properties v. Rogojski, J. pr. 53, 403; Péan de Saint-Gilles, A. Ch. [3] 42, 23; Vohl, J. pr. 95, 218; and A. Ch. [3] 42, 23; Vohl, J. pr. 95, 218; and Svensson, B. 4, 713). Some acid salts of the form Cu₂SO₃,xM₂SO₃,ySO₂, zaq have also been prepared (S. l.c.), and some salts of alkali sulphites with both Cu₂SO₃ and CuSO₃ (P. de St.-G., l.c.; R., l.c.).

Didymium sulphites. The normal salts

Di₂(SO₃), was obtained, as a reddish white powder, by passing SO₂ into water with Di₂O₃ in suspension, and boiling off excess of SO₂ (Marignac, A. Ch. [8] 58, 148; Cleve, Bl. [2] 89, 161).

tes. No gold sulphite has

Double salts of Au,SO,
and Na,SO, of the form Gold sulphites. been isolated. with Am, SO, Au,SO,3M,SO, Saq are known; also a Ba salt Au,SO,3BaSO, aq. The Na salt is obtained by adding Na,SO,Aq to a boiling alkaline solution of NaAuO₂, or by saturating NaAuO₂Aq at 50° with SO₂, then carefully adding BaCl₂Aq to the solution till free H₂SO₃ and H₂SO₄ are ppd., filtering, adding more BaCl₂Aq, quickly filtering off the purple-red Au₂SO₃.3BaSO₃, aq that separates, washing the pp. rapidly out of contact with air, decomposing it by the proper quantity of Na₂CO₃Aq, adding some alcohol to the solution, filtering off any Ba salt that ppts., and adding more alcohol, when the Na salt separates as an orange-red, very easily decomposed, pp. (v. Himly, A. 56, 252; 59, 95). When AuCl₂Aq is added, drop by drop, to a warm solution of (NH_.)₂SO₃ in cone. NH₂Aq, white, lustrous, six-sided plates separate of the salt (NH_.)₂SO₃3(NH₂Au)₂SO₃. 3aq; the inother-liquor from this salt yields the salt Au₂SO₃.3(NH₄)₂SO₃. 3aq, very similar to the corresponding Na salt (Haase, Z. 1869. 535).

Indium sulphites. The only stilt that has been isolated is a basic salt 2In2O3.3SO2. 8aq. Obtained by boiling a solution of a salt of In with excess of NaHSO3Aq; insol. water, sol. in dilute acids; loses 3H,O at 100°, and all water

at 260°; decomposed at 280°, giving off SO₂ and leaving In₂O₃ (Bayer, A. 158, 372).

Iridium sulphites. The normal iridic salt Ir₂(SO₃)₃. 6aq is obtained, in yellow crystals, by passing SO₂ into water with IrO₄H₃ in suspension, filtering and evaporating. The salt loses all water at 160°-180°; at a higher temperature Ir.O, remains; sl. sol. water, easily sol. acids; decomposed by boiling with KOHAq with separation of Ir₂O₃ (Birnbaum, A. 136, 179). The insoluble matter that remains on treating IrO, H, in water with SO₂ is a basic salt Ir.O₂.SO₂. 4aq (Birnbaum, l.c.). Double salts of iridous sulphite were obtained by Seubert (B. 11,1761) in separating Ir from Rh by means of Na2SO (by Bunson's method, A. 146, 274). Seubert gave the formulæ IrSO₃.3Na₄SO₃, 10aq and IrH₂(SO₃)₂.3Na₄SO₃, xaq, x being = 4 and 10,

Iron sulphites. The normal ferrous salt FeSO₃, 3aq is formed, along with FeS₂O₃, by dissolving iron wire in SO2Aq out of contact with air; on evaporating (out of air) the sulphite crystallises out, leaving the thiosulphate in solution (Fordos a. Gélis, J. Ph. [3] 4, 333; cf. Koene, P. 63, 245, 631; also Muspratt, P. M. [3] 30, 414). Sl. sol. water, easily sol. SO Aq; loses H2O, and then (at 250°) SO₂, on heating. Basic ferric salts are formed by reacting on ferric salt solutions with alkali sulphites; on adding alcohol to the red liquids thus formed, Koene (P. 63, 245, 481) obtained the salts Fe,O, SO, 6aq and 2Fe,O, 38O, tained the sins rely, sol, out and arely, sol, (cf. Muspratt, l.c.). By passing SO, into water with FeO,H, in suspension, and adding KOHAA, Muspratt (l.c.) obtained the double sals Fe,O, SO, 2K,SO, 5aq.

Lead sulphites. Only the normal salt PbSO, has been obtained; a white powder, insol. water, formed by adding Na.SO.Aq to solution of a salt of Pb (confirmed by Röhrig, J. pr. [2] 37, 217).

Lithium sulphites. The normal salt Li.SO, aq is prepared by passing SO, into water with Li.CO, in suspension, till CO, ceases to be given off, and evaporating on a water-bath or over H₂SO₄ (Röhrig, J. pr. [2] 37, 217). Danson (C. J. 2, 205) represented the salt as a hexahydrate. By adding other to the solution obtained from Li, CO, as described, R. got the dihydrate Li,SO, 2aq. Easily sol. water, somewhat sol. alcohol, very sl. sol. ether; oxidised in moist air. Röhrig failed to obtain an acid salt. By adding the proper quantity of K2CO, to the acid solution of Li₂CO₂ in SO₂Aq, evaporating to a syrup, and placing in a freezing mixture of snow and salt, R. obtained the double salt 2LiKSO₂ aq; by a similar process he got monoclinic crystals of

6Li,8O, Na,8O, 8aq (J. pr. [2] 37, 217).

Magnesium sulphites. The normal salt MgSO₃. xaq is formed by suspending magnesia alba in water, passing in SO2, and concentrating the solution (Rammelsberg, P. 52, 89); if evaporation is carried on over H₂SO₄ (Röhrig, l.c.), or in vacuo below 100° (Hartog, C. R. 104, 1793), the hexahydrate separates; if evaporation proceeds above 100° the trihydrate is obtained Muspratt, l.c.; R., l.c.; H., l.c.). Slowly oxidises in air to sulphate: loses all water at 200°; when more strongly heated the salt loses SO, and

leaves MgO.

Double salts with (NH,),SO, are formed by mixing the constituents and evaporating; also by dissolving MgO.H₂ in cold (NH₄)₂SO₃Aq (Rammelsberg, P. 94, 507; Hartog, l.c.). **Manganese sulphites.** Several hydrates of

the normal manganous salt MnSO, have been described. By adding alkali sulphite solution to dilute MnCl_Aq so long as the pp. that forms dissolves again, and then letting stand, monoclinic crystals of the trihydrate MnSO₃. 3aq are obtained; this hydrate is also formed by mixing 10 p.c. of MnSO₄Aq, acidified with acetic acid, and Na₈SO₄ (Deniges, Bl. [3] 7, 569); if Na₈SO₄Aq is added to hot dilute MnCl₄Aq the monohydrate is said to be produced. (Rammelsberg (P. 67, 245, 391) gives the formula 2MnSO, 5aq to the salt obtained by reacting on Mn acetate solution with Na, SO, Aq, and this is confirmed by Röhrig (J. pr. [2] 37, 217; cf. also Muspratt, P. M. [3] 30, 414). Double salts MnSO, K, SO, and 2MnSO, K, SO, were prepared by Gorgeu (C. R. 96, 376) by saturating 20 p.c. K₂SO₂Aq with SO₂, adding 4 p.c. MnSO₃. 3aq, and evaporating over an absorbent of SO₂; double Mn-Na salts are also described by G. (l.c.).

Mercury sulphites. According to Péan de Saint-Gilles (C. R. 34, 905) the normal mercuric salt HgSO, is formed by adding dilute Na SO Aq to a very conc. solution of Hg(NO₃)₂ free from excess of acid; it is, however, difficult to obtain the salt free from basic sulphites. basic mercuric sulphite 2HgO.SO, was obtained pure by P. de St.-G. by using solution of basic mercuric nitrate. The normal salt is easily decomposed; boiling water produces Hg, SO, and Hg. Boiling water is said (P. de St. G., l.c.) to convert the basic salt into the isomeric compound Hg,SO, (2HgO.SO₂ = Hg,O.SO₃). Divers a. Shimidzu (C. J. 49, 533) say that formal mercuric sulphite cannot be isolated; the reac-tion of Na,SO,Aq with Hg(NO₃)Aq produces at first the basic salt 2[2HgO.SO₂], aq, and then a

salt which is most simply represented at HgSO₂.Hg₂SO₂. 4aq, and which is called mercurosic (or mercuro-mercuric) sulphite by D. a. S., and represented by them as

 $H_g < SO_2 O > Hg_2$, 4aq. D. a. S. represent the basic salt as Hg SO, OHgO Hg. aq, and call it

mercuric oxysulphite.

For the best conditions of preparation of 2HgO.SO₂ v. D. a. S., l.c., p. 550, and for the reactions of this salt v. ibid. pp. 546-50; for preparation of mercurosic sulphite v. ibid. p. 564. and for the reactions of this salt, pp. 559-63.

By adding dilute Na SO, Aq to moist Hg SO, or to HgNO, Aq, D. a. S. (l.c., p. 572) obtained a greyish-black amorphous solid to which they gave the formula Hg, (SO,)2. aq, the constitution Hg SO 0 Hg3 aq, and the name mercuric hupomercurous sulphite or hypomercurosic sulphite. For the best method of preparing this salt (action of SO,Aq on Hg,SO, or Hg,NO,) v. D. a. S., l.c., p. 571; for the reactions of the salt v. pp. 567 70. It is evident that the formula given to this sait is the same as that of normal mercurous sulphite (Hg,(SO₃)₂=2Hg₂SO₃); the salt is produced from mercurous compounds, and in many of its reactions yields mercurous compounds; D. a. S. insist that the salt belongs to a new class of Hg compounds that contain what they call the 'hypomercurous radicle.'

By treating solid HgCl, with NaHSO, Aq, Wicke (A. 95, 176) obtained a solution that deposited a white crystalline powder to which he gave the composition $Hg(HSO_3)_2$ —i.e. acid mercuric sulphite. According to D. a. S. (l.c., p. 554) the pp. is HgSO₂.Na₂SO₃.aq. By reacting on HgO with SO₂Aq a white solid is formed, together with a solution containing a compound of Hg. Rammelsberg thought that the white solid was a basic mercurous sulphite of varying composition, and that the solution contained Hg₂SO₄ (P. 67, 405; the reaction was also examined by P. de St.-G. and by Vogel). D. a. S. say that the white residue is HgSO, Hg₂SO, 4aq (mercurosic sulphite, according to D. a. S.); by using freshly ppd. HgO suspended in water, and adding a little of this to SO, Aq (nearly free from H2SO4), D. a. S. obtained a clear solution which reacted as a solution of HgSO, in H2SO, and which they regarded as a solution of acid mercuric sulphite, Hg(HSO₃)₂ (v. l.c., pp. 554-8). Several double salts of mercuric sulphite with alkali sulphites have been isolated. The chief are HgSO, M,SO, xaq, where M = NH, K, or Na, and 2HgSO, Na,SO, aq (v. P. de St.-G., C. R. 34, 905; Hirzel, A. 84, 258; D. a. S., Le., pp. 538-46). D. a. S. regard these double salts as alkali derivatives of the hypothetical acid Hg SO OH (they greatly doubt the existence of the salt 2HgSO, Na, SO, described by P. de St.-G.); this view is confirmed by Barth's measurements of the electrolytic conductivities, and the freezing-points, of solutions of these salts (Z. P. C. 9, 176); Barth's results point to the

dissociation in dilute aqueous solution of these salts into three ions, HgS₂O_s, R, and R'. Nickel sulphites. The normal salt NiSO_s, Saq separates, in green tetrahedric erys.

tals, on slowly evaporating a solution formed by passing 80, into water with NiO. zaq in suspension (Rammelsberg, P. 67, 391). By boiling the solution of NiO. zaq in SO,Aq, Muspratt (P. M. [8] 30, 414) obtained a tetrahydrate NiSO. 4aq; this hydrate was also obtained by Röhrig (J. pr. [2] 37, 217) by quickly evaporating the solution at c. 150°. The compound with ammonia, NiSO, 3NH, 3aq, separates, as a blue crystalline

pp., on adding alcohol to an ammoniacal solution of NiSO₄ (Rammelsberg, l.c.).

Osmium sulphites. The normal salt OsSO₃ was obtained by Claus (J. pr. 90, 65) by treating OsO₃Aq with excess of SO₂, and evaporating or deline No. Os. No. No. SO₃ and evaporating or adding Na₂CO₃ or Na₂SO₄; after drying the salt is a blackish-blue powder, insol. water, sol. HClAq without giving off SO₂, reppd. from this solution by KOH or K₂CO₃, decomposed to K₂SO₃ and OsO. xaq by long boiling with conc. KOHAq. When moist the salt oxidises in air to OsSO. The double salt OsSO, 2K,SO, 2KHSO, 4aq was obtained by Claus (A. 63, 355) as a pale rose-red crystalline powder, by heating K,OsCl, with K,SO,Aq.

Palladium sulphites. Only the double pallado-sodium salt PdSO, 3Na, 3O,, 2aq has been isolated; a white pp. obtained by dropping NaOHAqinto PdCl₂Aq, after adding SO₂ (Wöhler,

A. 174, 199).

Platinum sulphites. Neither platinosulphite PtSO₃ nor platinisulphite Pt(SO₃)₂ has been isolated. Several salts which may be regarded as double compounds of PtSO₃, but are better classed as platinosulphonates or platinosulphites, have been obtained; they are shortly described under PLATINO-SULPHONATES (this vol., p. 285). By passing SO, into water with PtO,H, in suspension, and adding alkali sulphites to the dark-red liquid so formed, Birnbaum (A. 139, 172) obtained double salts of the form PtO SO. M. SO. and the form of the form the form PtO.SO₃.xM₂SO₃.yaq, where M = K or Na, x varied from 1 to 2, and y also from 1 to 2. These salts gave no pp. of BaSO, with BaCl2Aq, with HClAq SO, was given off and PtCl, formed; hence they are better classed as double salts of platinyl sulphite, Pto.So, than of platinous sulphate PtSO.

Potassium sulphites. The normal salt K2SO2. 2aq is obtained, in large, deliquescent, monoclinic prisms, by passing SO2 into K2COAq as long as CO₂ is given off, and evaporating over H₂SO₄ at the ordinary temperature (Muspratt, P. M. [3] 30, 414). More soluble cold than hot water; decomposed by heat to K₂S and K₂SO₄ (Rammelsberg, A. 50, 259; results of M. and R. confirmed by Röhrig, J. pr. [2] 37, 217; v. also Hartog, C. R. 109, 179, 221, 436). The acid salt KHSO, separates in white needles on adding alcohol to a solution of the normal salt saturated with SO₂ (M., l.c.; confirmed by Röhrig, l.c.). By passing SO₂ into hot saturated K₂CO₃ till CO₂ ceased to come off and the solution was greenish, and then allowing to cool, Muspratt (l.c.) obtained hard monoclinic crystals of the acid salt K₂SO₂, SO₂ (= K₂S₂O₃), sometimes called pyrosulphite; only sl. sol. water; decomposed by heat to K₂SO₄, SO₂, and S (confirmed by Röhrig, l.c.). Dilute K₂SO₂Aq heated in a closed tube to 100° and then let stand is very slowly decomposed to K,SO, H,S,O, and S (Saint-Pierre, C, R, 62, 460; 73, 749). K,SO,Aq with KNO,Aq

gives K salts of various acids; v. Surruuz oxy-ACIDS, NITROGEN DERIVATIVES OF (p. 619).

Double sulphites of potassium and sodium. Schwicker (B. 22, 1728) obtained two socium. Schwicker (B. 22, 1729) obtained two distinct salts KNaSO, xaq; one by neutralising cone. KHSO, Aq by the proper quantity of Na,CO, and evaporating over H,SO, the other by adding K,CO, to NaHSO,Aq. Röhrig (J. pr. [2] 37, 217) ppts. the salts by adding alcohol, or better ether. The first salt, heated with EtI to 140°, gives 4(SO,Et.OK). NaI, the second gives 4(SO,Et.ONa). KI; hence the first salt seems to be NaSO, OK and the other KSO, ONa. Schwicker assigns different quantities of crystalline water to the salts, viz. NaSO, OK. 2aq and KSO, ONa. aq; Röhrig (l.c.) gives 2aq to both salts. The two Röhrig (l.c.) gives 2aq to both salts. salts seem to be isomeric. Aqueous solutions of these salts have identical electrolytic conductivities, as would be expected (Barth, Z. P. C. 9, 176). Schwicker (*l.c.*) also describes the salts KNa H(SO₃), 4aq and K₂NaH(SO₃), 3aq. Hartog (*R.* 109, 179, 221, 436) describes the salts (*K.* SO₂, 2Na SO₂, 5Qaq (= K₂O.2Na₂O.4SO₂, 9aq) and 2K₂SO₃(NH₂), SO₂SO₂, 9aq $(=2K_2O.(NH_1)_2O.4SO_2.9aq).$

For other double salts of potassium sulphite v. supra, cobalt sulphites, copper sulphites, iron sulphites, lithium sulphites, manganese sulphites, mercury sulphites, osmium sulphites, and platinum sulphites; and infra, ruthenium

sulphites and silver sulphites.

Rhodium sulphites. The normal rhodic salt Rh. (SO₃)₃. 6aq is prepared, as a yellowish crystalline mass, by dissolving RhO₃H₄. aq in SO₄Aq and evaporating; fairly sol. water, insol. alcohol (Bunsen, A. 146, 265). The double rhodous salt 4RhSO, 6Na,SO, 9aq is obtained by treating Na, RhCl, 12aq with excess of NaHSO, Aq (Bunsen, l.c.); it has been examined by Seubert a. Kobbé (B. 23, 2556), who prepared it by heating a solution of RhCl, 4aq with excess of NaHSO, Aq for some time, washing the pp. with cold water, and drying over P.O.. Pale-yellow solid; very sl. sol. hot water; dissolves in dilute HNO₃Aq, giving off SO₂; warmed with conc. H.SO₄ forms Rh₂(SO₄)₃.Na₅SO₄ (B., l.c.; S. a. K., l.c.).

Ruthenium sulphites. Only the double rutheno-potassium salt RuSO, K,SO, has been isolated; prepared by heating K,RuCl,Aq with K,SO,Aq till a dark-red solution is formed, evaporating to dryness, dissolving, again evaporating to dryness, and repeating these processes till a pure white residue is obtained (Claus, J. pr. 42, 351).

Silver sulphites. The normal salt Ag.SO, forms small, white lustrous crystals; obtained by treating AgNO, Aq with alkali sulphite solution or with SO,Aq; if excess of SO,Aq is allowed to remain in contact with the salt for Some time Ag is formed (H. Rose, P. 88, 240). Darkens in air (Muspratt, P. M. [3] 30, 414; Sodeau, C. N. 65, 102); products depend on method of preparation of the salt (v. Stas, Stas, Name P. Heatted close C. 114. Mouv. R.). Heated alone, or with water, to 100° gives Ag₂SO₄, Ag, and SO₂ (Berthier, A. Ch. [3] 7, 82; cf. Geitner, J. 1864. 142, who says that decomposition begins at 200°). Scarcely sol. water or SO₂Aq; sol. NH,Aq (Berthier, Le.), also in alkali sulphite solutions.

Double salts. AgNaSO, 2aq; small lustrous needles, formed by dissolving Ag,SO, in hot saturated Na,SO,Aq, letting cool, and pressing salt that separates (cannot be washed with water (Svensson, B. 4, 714). AgKSO₃, xaq, prepared like the Na salt. Svensson (l.c.) describes three double salts with (NH₄);SO₃, obtained by dissolving Ag₂SO₃, or AgCl, in (NH.), SO, Aq; he gives the formulæ Ag(NH.) SO,, Ag, SO, 6(NH.), SO,, 19aq, and Ag, SO, 3(NH.), SO, 4(NH.) HSO, 18aq.
Sodium sulphites. The normal salt Na, SO,

is prepared by completely saturating Na₂CO₃Aq with SO₂, warming, adding an equal quantity of the same Na₂CO₂Aq, evaporating, and crystallissame Na₂O₃Aq, evaporating, and crystanising above 33° (Rammelsberg, P. 56, 298; Schultz-Sellack, J. pr. [2] 2, 459). Also obtained by heating the hydrate Na₂SO₃. 7aq to 150°. Na SO, also crystallises from solution of NaHSO, that has been made strongly alkaline. Heated above 150° melts to a yellowish-red mass containing sulphide and sulphate in the ratio Na₂S:3Na₂SO₄ (R., P. 67, 246; 94, 507). The heptahydrate Na₂SO₃ 7aq is obtained by crystallising at the ordinary temperature a solution of Na₂CC₃ saturated with SO₂, warmed, and mixed with an equal quantity of the same according to Röhrig (J. pr. [2] 37, 217) only the heptahydrate exists.

The acid salt NaHSO, is formed by saturating Na₂CO₃Aq with SO₂ and cooling; better crystals are obtained by treating Na₂CO₃. 10aq with SO2 and evaporating the liquid so produced in SO₂. Easily sol. water, but less sol. than Na₂SO₂, 7aq. (For heat of solution v. De Forcrand, C. B. 98, 738.) Gives off SO₂ on exposure to air; SO₂ is also removed from Na₂SO₄ by researce of a principle of the solution of NaHSO₂Aq by passage of an indifferent gas (Gernez, O. R. 61, 606). When heated gives off H₂O, SO₂, and S, leaving Na₂SO₄; heated in a closed tube forms Na, SO, H., SO, S, and H.O (Barbaglia a. Gueci, B. 13, 2325). Reacts with I to give NaHSO, and NaI (Spring a. Bourgeois, Ar. Ph. 229, 707, where references are given to other experiments). Another acid salt Na₂SO₃.SO₂ (= Na₂S₂O₃), sometimes called pyrosulphite, is said to separate, in lustrous prisms, from conc. hot NaOHAq saturated with SO2

(v. Röhrig, l.c.).

Double salts with anmonium sulphite. Marignac (Ann. M. [5] 12, 30) described a double salt obtained by passing NH, into conc. NaHSO, Aq; the salt is probably identical with that described by Schwicker (B. numerical with that described by Schwicker (B. 22, 1728), to which he gives the formula Na₂SO₂,(NH₄)HSO₂, 4aq. By partially saturating conc. (NH₄)HSO₂ with Na₂CO₂Aq, Trauber (J. C. T. 1888. 44) obtained the salt 2Na₂SO₂(NH₄)₂O₂. 10aq; Hartog writes the formula of this salt 2Na₂O₂(NH₄)₂O₄. ASO₂, and says it orystallises with 9aq (O. R. 109, 179, 221, 486). For other double salts of Na₂SO₂ v. supra, cobalt sulphites, copper sulphites, gold sulphites, iridium sulphites, lithium sulphites, manganese sulphites, mercury sulphites, palladium sulphites, platinum sulphites, potassium sulphites, rhodium sulphites, and silver sulphites.

Strontium sulphites. The normal salt SrSO₃ is formed by passing SO₂ over SrO at 290° (Birnbaum a. Wittich, B. 13, 651); also by decomposing SrCl₂Aq by alkali sulphite solution. Small white crystals; slowly oxidises in air to sulphate (Muspratt, P. M. [3] 30, 414); gives SrS and SrSO, on heating (Forster, P. 133.

Thallium sulphites. The normal thallous salt Tl₂SO₃ is prepared by adding Na₂SO₃Aq to TLSO, Aq, and crystallising the pp. from warm water. White crystals; S. 3:34 at 15°; insol. alcohol; S.G. 6:427 at 20° (Scubert a. Elten, Zeit. f. anorg. Chem. 2, 434). The same salt was obtained by Röhrig (J. pr. [2] 37, 217) by passing SO, into solution of a thallous salt, evaporating at 100° or over H.SO., or adding alcohol.

Tin sulphites. Basic stannous salts, xSnO.2SO₂. 20aq, x being probably 5, 8, and 11, were obtained by Röhrig (J. pr. [2] 37, 217) by treating freshly ppd. SnO. xaq with SO₂Aq.

Titanium sulphites. Berthier (A. Ch. [3] 7,

77) made some observations, but described no definite salts.

Uranium sulphites. A basic uranous salt UO₂.SO₂. 2aq = U(OH)₂SO₃. aq is obtained, as a greyish-green pp., by adding Na SO Aq to UCl Aq (Rammelsberg, P. 56, 125; confirmed by Röhrig, J. pr. [2] 37,217). The uranyl salt UO, SO, xaq was obtained, in yellow prisms, by Muspratt (P. M. [3] 30, 414), by passing SO₂ into water with UO, in suspension, and allowing the solution so formed to evaporate at the ordinary temperature; Muspratt gave x=3, according to Röhrig (i.c.) x=4 (cf. Girard, C. R. 34, 22; and Reinele, P. 125, 238).

Zine sulphites. The normal salt

Zino sulphites. The normal salt 2ZnSO₃, 5aq is prepared by evaporating, or by adding alcohol to, a solution of ZnCO₃ in SO₂Aq (Rammelsberg, P. 52, 90); also by mixing cold 25 p.c. SnSO₄Aq acidified with acetic acid with cold 25 p.c. Na₃SO₃Aq, and letting stand (Denigès, Bl. [3] 7, 569). Muspratt (l.c.), Fordos a. Gélis (J. Ph. [3] 4, 363), and Koene (P. 63, 245, 431) give the formula ZnSO₃, 2aq; but Röhrig (J. pr. [2] 37, 217) confirms Rammelsherg's formula.

berg's formula.

Zirconium sulphites. Compositions of salts obtained by ppg. Zr salt solutions by alkali sul-

phites are doubtful (v. Berthier, A. Ch. [3] 7, 77; Hermann, J. pr. 31, 77).

HYPOSULPHITES. (Hydrosulphites.) Salts of the acid H.S.O., Hyposulphurous acid is known only in aqueous solution. Schützenberger (A. Ch. [4] 70, 351) obtained the Na salt, and an aqueous solution of the acid, in 1869; he gave the formula H,SO, to the acid; but Bernthsen (A. 208, 142; 209, 285; 211, 285) in 1881 showed that the acid has the composition H.S.O., This acid corresponds with the oxide $S_2O_3(S_2O_4 + H_1O = H_2S_2O_4)$. Schützenberger prepared the Na salt by digesting conc. NaHSO₃Aq with zinc shavings in a closed flask for c. half an hour, pouring the liquid from the crystals of the double Na-Zn sulphite which formed (this is a basic Zn-Na sulphite, according to Bernthsen, A. 211, 297) into a flask about three-fourths filled with conc. alcohol, allowing to stand for

some time in the closed flask, and then pouring off into flasks, each flask being quite filled with the liquid and then sealed; after a time crystals of the hyposulphite were formed, to which S. gave the composition NaHSO. Bernthsen (l.c.) after reducing NaHSO, Aq by Zn, pouring off from the double sulphite formed, &c., removed sulphite and sulphate by adding BaCl, Aq; he then filtered and titrated the solution by ammoniacal CuSO, Aq, which is decolourised by Na.S.O, Aq to a cuprous salt (and eventually to Cu.II, and Cu.S). For details of the method of analysis v. Bernthsen (B. 13, 2277; A. 211, 292 note). B. failed to obtain Na S.O. free from Na SO., Na SO., Na₂S₂O₃ and Zn salts.

B. expresses the first part of the reduction of NaHSO₃ by the equation $4NaHSO_3Aq + Zn = Na_2S_2O_1Aq + ZnSO_3 + Na_2SO_3Aq + 2H_2O$, and the

complete change by the equation 10NaHSO, Aq + 3Zn =

 $3{\rm Na}_2{\rm S}_2{\rm O}_4{\rm Aq} + {\rm Na}_2{\rm SO}_3{\rm Aq} + {\rm Zn}_3{\rm Na}_2{\rm S}_3{\rm O}_{10} + 5{\rm H}_2{\rm O}.$ Moist sodium hyposulphite is rapidly oxidised in air to Na SO,; when dry it is unchanged in O; it is easily sol. water, less sol. dilute alcohol, and insol. cone. alcohol; but according to B. even approximately pure Na S2O, has not been Na2S2O1Aq is oxidised by iodine so-

By heating Na.S₂O₄Aq with an equivalent quantity of II.SO₄Āq or H₂C₂O₄Aq, an aqueous solution of hyposulphurous acid II.S.O.Aq is obtained; this solution is an energetic reducer, decolourising indigo, and reducing salts of Cu, Hg, Ag, &c.; the solution rapidly decomposes in air with separation of S. M. M. P. M.

SULPHO Use of this prefix applied to inorganic compounds: for sulpho- compounds and sulpho-salts v. the compounds or salts to the names of which sulpho- is prefixed; thus sulpho-molybdates are described under MOLYBDATES; but the prefix thio- is used in almost every case in preference to sulpho- to denote the replacement of O by S. Sulphocyanides and similar compounds are described under Cyanides : sulphocyanic anhydride is described as Cyanogen BULPHIDE.

SULPHO-ACETIC ACID C,H,SO, SO₃H.CH₂.CO₂H. [75°].

Formation.-1. By adding SO, to cooled HOAc (Melsens, A. Ch. [3] 5, 392; 10, 370; A. 52, 276) .- 2. By the action of fuming II SO, on acetamide or acetonitrile (Buckton a. Hofmann, C. J. 9, 247).—3. By boiling chloro-acetic acid with aqueous K_2SO_3 (Strecker, Z. [2] 4, 214; Collmann, A. 148, 109).—4. By heating Ag₂SO₄ with AcCl at 120° (Kämmerer a. Carius, A. 131, 165).-5. By boiling chloro-acetic acid with ammonium sulphite solution (Hemilian, A. 168, 145).—6. By heating Ac₂O with H₂SO, at 130° (Franchimont, C. R. 92, 1054; cf. Baumstark, A. 140, 83).—7. By heating ClSO₂H with HOAc the 140° (Baumstark). at 140° (Baumstark).—8. By oxidation of isethionic acid by CrO₃ (Carl, B. 14, 63).

Properties. - Deliquescent crystals (containing 1 aq) giving off water of crystallisation at about 160° and decomposed at 230° into CO, SO, acetic acid, and other products (Franchimont, R. T. C. 7, 25). V. sol. water. Its salts are sol. water, insol. alcohol. PCl, acting on the Nasalt forms CHCl(SO₂Cl).COCl (R. Siemens, B. 6, 659). Vol. IV.

Salts.—K,A" aq: hard crystals.—KHA"; six-sided tables.—BaA" aq. S. 267. at 20°. six-sided tables.—BaA" aq. S. 267 at 20°.—BaA"Et,SO, (Laube, A. 218, 258).—CaA" aq.—

PbA": radiating needles.—Ag,A" ag: flat prisms.

Mono-ethyl ether EtHA". Formed by passing HCl into the Ag salt suspended in alcohol. Syrup, v. sol. water.—AgEtA": plates. Ethyl ether Et.A". Oil. Formed, together with C₆H₁₁Ag₂S₄O₁₈ by the action of Ag₂A" on EtI (F.). May be distilled (Mauzolius, B. 21,

Sulpho-diacetic acid v. DI-METHYL SULPHONE DICARBOXYLIC ACID.

Di-sulpho-acetic aldehyde C.II.S.O. CH(SO,H), CHO. By adding chloral hydrate to conc. KHSO, Aq at 80° there are formed crystals of C.H.K.S.O.K.HSO., and these when boiled with HClAq yields C.H.K.S.O. aq, from which C.H.BaS.O. 2aq may be prepared (Bathke, A. 161, 154). Boiling K.CO., yields C.H.(SO.K.), potassium formate, and K.SO.

SULPHO-AMIDO-BENZOIC ACID v. AMIDO-

RULPHO-BENZOIC ACID.

DI-SULPHO-ANILINE v. DI-AMIDO-DI-PHENYL DISHLPHIDE

(B.) - SULPHO - ANTHRACENE - (A) - CARB. OXYLIC ACID C.H. CCH >C.H. (SO.H).

[above 360°]. Obtained by dissolving anthracene-(A.)-carboxylic acid in cold cone. II.SO, and allowing to stand for 12 hours on ice (Behla, B. 20, 706). Minute yellowish prisms (from alcohol). V. sol. water and alcohol, insol. benzene and ether. The aqueous solutions of the acid and its salts have a strong blue fluorescence .-BaA": very soluble vellowish minute prisms.

Di-sulpho-anthracene-(A.)-carboxylic acid C₁₁H₂(SO₂H)₂.CO₂H. [above 360°]. Formed by disselving anthracene-(A.)-carboxylic acid in cold fuming H.SO₁ (Behla). Yellow prisms (from alcohol). V. sol. water and alcohol, insol. benzene. Its aqueous solution scarcely fluoresces. but the cone. H₂SO₄ solution has a strong yellowish green fluorescence. - A'''₂Ba: very sparingly soluble crystalline powder.

SULPHOBENZIDE v. DI-PHENYL SULPHONE. o-SULPHO-BENZOIC ACID C, HaSO, i.e.

C₈H₁(SO₃H).CO₂H. S. 50 in the cold. Formation.—1. Together with its imide, by oxidation of toluene o-sulphonic amide with KMnO₄ (Remsen a. Fahlberg, Am. 1, 433).—2. By heating the imide with HGlAq at 100 '(Fahlberg a. Remsen, B. 12, 472; Fahlberg a. Barge, B. 22, 754; Brackett a. Hayes, Am. 9, 399). this means the acid ammonium salt is first obtained (F.; Remsen a. Dohme, Am. 11, 332). -3. By boiling o-diazo-benzoic acid with alcoholic SO₂ (Wiesinger, B.•12, 1349). -4. By oxidation of toluene o-sulphonic acid by KMnO₄.

Properties. - Trunctric crystals (containing 3aq or 4aq); a:b:c = .551:1: .812, v. e. sol. water, sol. alcohol, insol. ether. According to Fahlberg (B. 22, 754), it crystallises with 3aq, and is decomposed at 105°. According to Remsen (Am 11, 332), it crystallises with 4aq, melts at 69° ic its water of crystallisation, melts at 130° wheat anhydrous, and gives a sublimate of long needles (containing 2aq). Resorcin (1.2 pts.) at 195° forms 'sulphofluorescein' $C_{19}H_{12}SO_{2}$ 2aq, which fluoresces in aqueous and alkaline solutions (Remsen a. Hayes, Am. 9, 872). By condensation of resorcin (4 mols.) with o-sulpho-benzoic acid there is likewise formed a similar body C₁₁H₂₀SO₈4aq (Fahlberg a. Barge, B. 22, 765).

C₁₁H₂₂SO₄4aq (Fahlberg a. Barge, B. 22, 765). Potash-fusion gives salicylic acid.
Salts.—KHA": transparent plates, sol.
water.—K₂A" 2aq.—Ba(HA")₂ 2½aq: needles, sol.
water. — Ba(HA")₂ 2aq. — BaHA" 2, 4½aq. —
BaA" 2aq. — Ca(HA")₂ 6aq. — ČaA" 5aq. —
CuA" 3½aq. — Ag₂A". — C₆H₄(SO₄NH₄).CO₂H.
Formed by heating the imide with HClAq at

Anhydride
$$C_0H_4 < SO_{SO} > 0$$
. [119°] (F.)

Anhydride C₀H₄<SO₂>0. [119°] (F.). [128°] (Remsen a. Dohme, Am. 11, 332). Formed by heating the K salt with PCl_s at 180° or the acid with P₂O₅ at 130°. Monoclinic tables, insol. cold water. NH₃ passed into its solution in benzene forms $C_0H_1(CONH_2)SO_2ONH_1$ [256°], which crystallises from alcohol in needles.

Chloride C,H,(SO,Cl).COCl. [73°]. Prisms (from ether). When reduced by zinc-dust and H2SO, it yields C. II (SH). CO. H (Delisle, B. 22,

2205).

Amic acid C_uH₁(CO.NH₂)SO₃H. Crystals (containing aq), v. sol. alcohol and water. Got by the action of H₂S on C₂H₁(CONH₂).SO₃Ag aq, which is obtained by adding silver nitrate to C₀H₄(CONH₂).SO₃NH₄ prepared as above (Fahlberg a. Barge, B. 22, 760).

Amic acid C₈H₁(SO₂NH₂).CO₂H. Sulphamine-benzoic acid. Formed by boiling toluene o-sulphonic amide with K₃FeCy₆ and aqueous potash (Noyes, Am. 8, 178; cf. Fahlberg, Am. 1, 170). Slunder needles or prisms, v. sol. water, alcohol, and ether. Melts at 155° when slowly heated, and at 167° when quickly heated. At 180° it is completely converted into imide. Gives rise to the salts MgA', 6\[\]_40, BaA', 2\[\]_40, BaA', 2\[\]_40, BaA', 2\[\]_40, BaA', and Ag,C,H,NSO. By passing HCl into an alcoholic solution of the imide, the ether C,H,(SO,NH,),CO,Et (S3°) is formed. The methyl and propyl ethers have also been obtained and may be converted by aniline into $C_0H_1(SO_1NH_2)$.CONHPh [189°], by o-toluidine into $C_0H_1(SO_1NH_2)$.CONHC.H. [193°], and by means of p-toluidine into the isomeric p-toluide $C_0H_1(SO_2NH_2)$.CONHC.H. [202°].

Imide C.H. SO2>NII. Saccharin. [220°]

(Remsen a. Fahlberg, Am. 1, 432). Formed by oxidising CH₂C₂H₄.SO₂NH₂ with KMnO₄ in neutral solution (Remson a. Fahlberg, B. 12, 469; Remson a. Fahlberg a. List, B. 20, 1597; 21, 242; Remson a. Linn, Am. 11, 73). Elongated triangular plates (by sublimation), sl. sol. cold water, v. sol. alcohol sudimation), st. sol. cold water, v. sol. alcohol and ether. Has a very sweet taste (500 times that of cane sugar). The solubility of commercial saccharin is given by Gravill (Ph. [8] 18, 337) as S. (water) 2 at 15°; 6 at 100°; S. (alcohol) 5·4 at 15°; S. (ether) 1·3 at 15°. According to Stift (B. C. 18, 458) and Aducco and Mosso (C. C. 1887, 1148) it retards digestion, and is autisentic. The imide is converted into and is antiseptic. The imide is converted into and is antisepile. The initial is obtained with $C_0H_1(SO_2NH_2),CO_2H$ on evaporation with $KOHA_0$. Conc. hydrochloric acid at 150° forms $C_0H_1(SO_2NH_1),CO_2H$. The imide gives rise to salts of the form $C_0H_1 < \frac{SO_2}{CO} > NAg$, of which the following have been described.-KA' aq: prisms, v. sol. water .- NaA' 2aq : tables .-

BaA', 1\frac{1}{2}aq.—BaA', 4aq (Noyes, Am. 8, 180).—AgA': needles (from hot water). To detect 'saccharin,' a suspected liquid may be acidified. extracted with ether, the ether evaporated, the residue fused with NaOH, and the product tested for salicylic acid and for sulphate (C. Schmitt. Fr. 27, 396; Allen, An. 13, 105; Börnstein, Fr. 27, 165). 'Saccharin' evaporated to dryness on a water-bath leaves a residue which, when warmed with alcoholic potash, exhibits yellow, blue, and red colours (Lindo, C. N. 58, 51, 155).

Methylimide $C_0H_1 < \frac{SO_2}{CO} > NMe$. [132°].

Formed by heating $C_eH_4 < SO_2 > NAg$ with MeI at 100° (Brackett, Am. 9, 406). Long flat needles, sol. ether, alcohol, and hot water.

 $C_{\alpha}H_{4} <_{\rm CO}^{\rm SO_{2}} > NEt.$ Ethylimide [97°].

Needles (from water). Converted by boiling alcoholic potash into C₀H₁(SO₂NHEt).CO₂H [116°], which yields C₀H₁(SO₂NKEt).CO₂K crystallising in nacreous scales, Na₂C₂H₂NSO₁, CuA'₂ 2aq, and AgA' (Fahlberg a. List, B. 20, 1596).

Propylimide C, H, SO, NPr. [60°-70°]. m-Sulpho-benzoic acid

[1:3]C,H,(SO,H).CO,H.

11:3)_C, R₄(SO₃H). OO₂H.

Formation.—1. By mixing benzoic acid (2 pts.) with SO₃ (1 pt.) (Mitscherlich, P. 31, 287; 32, 227; Barth, A. 148, 33).—2. By heating BzCl with Ag₂SO₄ at 150° (Kämmerer a. Carius, A. 131, 153; B. 4, 219).—3. By heating BzCl with H₂SO₄ (Oppenheim, B. 3, 735).—4. By the action to a character of SO₂ are discovered. action of an alcoholic solution of SO2 on m-diazobenzoic acid (Wiesinger a. Vollbrecht, B. 10, 1715).—5. By oxidation of *m*-sulpho-benzoic aldehyde with air at 95° (Kafka, B. 24, 796).

Properties.—Deliquescent crystalline mass. Yields m-oxy-benzoic acid when fused with

potasb.

potash.

Salts.—NaHA" 2aq: triclinic crystals.—
Na_A"Me_SO_4 (Stengel, A. 218, 260). Crystals.—
Na_A"Et_sO_4: v. sol. water.—KHA" 2\(\frac{1}{2}\)aq.—
KHA" 3aq (Otto, A. 122, 155).—BaA" 3aq: v. sol. water (Fehling, A. 27, 322).—BaH_A" 2aq.
White monoclinic prisms. S. 5 at 20° (M.).—
BaA"Me_SO_4.—BaA"Me_SO_4 3\(\frac{1}{2}\)aq. S. 34 at 21°.
—BaA"Et_sO_3 3\(\frac{1}{2}\)aq. S. 31 at 21°. Formed from the acid NaHSO. -BaA'Et,SQ, 3,3aq. S. 31 at 21°. Formed from the acid, NaHSO,, and alcohol (Stengel). Long needles.—BaA''Tr,SQ, 7aq. S. 11 at 19°.—PbA''2aq: stellate groups of white needles.—PbA''Et,SQ, 2,3aq.—CuA''Me,SQ, 2,3aq. Crystals.—CuA''Et,SQ, 2,3aq.—AgHA'': nodules (Limpricht a. Uslar, A. 106, 50).—Ag,A''aq: small yellowish prisms.

Mono-ethyl ether EtHA". Formed by the action of alcoholic NH, on Et, A" or on the chloride (Limpricht a. Uslar, A. 102, 252). The free acid is unstable.—EtNH,A": four-sided triclinic tables (Keferstein, A. 106, 385).—
NaEtA"xaq. — Ba(EtA")₂xaq: efflorescent tables.

Ethyl ether Et,A". Formed from the chloride and alcohol. Syrup, miscible with water. Saponified by heating with water. Semi-chloride C.H.SO.Ol. Formed by

heating the acid (1 mol.) with PCl_s (1 mol.) (L. a. S.). Formed also by leaving the chloride C.H. (SO, Cl) (COCl) in contact with water for several weeks. Crystalline powder, sol. ether. Converted by hot water into the acid.

Chlorids C.H.(SO.Cl).COCl. Formed by heating the acid (1 mol.) with PCl, (2 mols.) at 100°. Thick oil, slowly decomposed by water. Yields C.H.(Cl.COCl on distillation and on heating with PCl, at 150° (Kämmerer a. Carius, A. 131, 159).

Benzoyl derivative $C_{11}\Pi_{10}SO_{g}$. The first product of the action of BzCl (2 mols.) on Ag SO, (1 mol.) (K. a. C.). Amorphous, sol. ether. Resolved by water into benzoic and sul-

phobenzoic acids.

Amic acid CaH, (SO2NH2).CO2H. nhamine-benzoic acid. [235° uncor.] (R. a. P.); [247°] (N. a. W.). Formed by the action of conc. KOHAq at 100° on the amide (Limpricht a. Uslar, A. 106, 27). Prepared by oxidation of [1:3] C_aH₁Me.SO₂NH₂ with alkaline KMnO₄, with chromic acid mixture (Remsen a. Palmer, Am. 4, 143), or with alkaline K, FeCy, (Noyes a. Walker, Am. 8, 188). Scales (from water), sl. Yanker, Ans. 6, 188). Scales (from water), st. sol. cold water, v. sol. alcohol. Converted by PCl, at 150°-200° into the oily chloride C₆H₄(SO₂NH₂)COCl. — BaA'₂ 4aq. — AgA' aq. — Ag₂C, H₂NSO₄: amorphous pp., sol. hot water.— EtA'. Monoclinic crystals, sl. sol. hot water.

Amide C₈H₄(SO₂NH₂)(CONH₂). Formed from the chloride and conc. NII, Aq. Small anhydrous crystals (from alcohol) or needles (containing aq). V. sol, hot water and alcohol. PCl₂ at 100° forms C₂H₄(SO₂NH₂)CCl:NH, which is decomposed by distillation into mchloro-benzonitrile, SO, and NH, ; and by treatment with NH, Aq into C, H, (SO, NH,).CN [152°] (Wallach a. Huth, B. 9, 428).

Anilide C. H₄(SO₂NHPh).CONHPh.

Formed from the chloride and aniline. Small crystals (from alcohol).

Isomeride of the amic acid

C, H, C(NH2): N.SO, H. Benzamidine v-sulphonic acid. [247°]. Mol. w. 200 (obs.). Formed by passing SO, into cold benzonitrile (Engelhardt, J. pr. 75, 363; Eitner, B. 25, 471). Prisms and rhombohedra. Converted by HClAq into benzamidine sulphate. - CaA'2. - BaA'2 4aq.

Amorphous isomeride of the

acid. A product of the action of PCl₃ on the amic acid (L. a. U.). Insol. water, alcohol, and ether. Forms amorphous salts. Water at 180° reconverts it into the ordinary amic acid.—
BaA'₂4aq: brittle mass.
p.Sulpho-benzoic acid

[1:4] C_aH₄(SO₃H).CO₃H, [c. 200°]. Formed, in small quantity, together with the m- isomeride, by the action of SO₂ on benzoic acid (Remson, A. 178, 275; Z. [2] 7, 81, 199). Formed also by oxidation of toluene p-sulphonic acid with KMnO₄ (Hart, Am. 1, 342), and by the action of an alcoholic solution of SO₂ on diazotised p-amido-large in the contract of Windows P. 100, 2715. benzoic acid (Wiesinger, B. 10, 1715). Needles, not deliquescent, decomposed by heat. Potashfusion converts it into p-oxy-benzoic acid. The K salt heated with potassium formate yields terephthalic acid.

Salts.—NaHA" 21 aq. Stellate groups of prisms, m. sol. cold water.—BaA"2aq: groups of needles, m. sol. cold water.—BaH₂A"₂ 3aq:

flat needles, v. sl. sol. cold water.

Amic acid C.H.(SO.NH.).CO.H. [c. 280°].

Formed by exidation of C.H.Me.SO.NH. and of

p-sulpho-cinnamic amide (Remsen, A. 178, 299; Fahlberg, Am. 1, 170; Palmer, Am. 4, 164; Noyes, Am. 7, 145; 8, 182). Flat prisms (from water), sl. sol. hot water, v. sol. alcohol. composed on fusion.—NH,A': needles or long lamine, v. sol. water.—BaA', 5aq.—AgA': v. sl. sol. hot water.—C₄H₄(SO₂NHAg).CO₂Ag: v. sol. hot water.—EtA'. [111°].

Di-sulpho-benzoic acid $C_1H_0S_2O_8$ i.e. $C_0H_3(SO_3H)_2CO_2H$ [4:2:1]. [above 28501 C_aH_a(SO₄H)₂CO₂H [4:2:1]. [above 285°]. Formed by oxidation of toluene disulphonic acid with chromic acid mixture (Blomstrand a. Hakansson, B. 5, 1088; Brunner, Sitz. W. [2] 78, 665) and by digesting $C_aH_a(SO_aNH_a) < SO_a > NH$ with HClAq at 160° (Fahlberg, Am. 2, 190). Large crystals (from HClAq), sol. cold water,

insol. alcohol and ether. Yields (4,2,1)-di-oxy-

hiso. alcoho and center. Theos (a,z,1)-di-oxybenzoic acid on fusion with potash.

Salts.—K₃A" 2aq: prisms, v. c. sol. water.—

K₁IIA"aq: large crystals, sl. sol. water.—

Ba₃A"₂7aq.—Cu₃A"₂7aq: minute crystals.

Amic acid C₂I₄(SO₄II)(SO₂NI₂).CO₂H

[2:4:1]. [165°]. Formed by boiling the imide of the amic acid with dilute HClAq for five hours. Large crystals, v. e. sol. water, sl. sol. HClAq, insol. ether.—HKA": crystals (from dilute HClAq), v. e. sol. water.

Di-amic acid C_aH₃(SO₂NH₂)₂CO₂H. [183°]. Formed by heating C_aH₃Mc(SO₂NH₂)₂ with aqueous potassium permanganate and by evaporating C₆H₄(SO₂NII₂)<SO₂>NII with KOHAq (Fahlberg, Am. 2, 186; B. 21, 246). Minute sating needles, v. e. sol. water and alcohol, sl. sol, ether. Tastes acid. Decomposes completely at 250°-260°. Its salts are crystalline. Those of alkalis and alkaline earths are v. sol. water. - BaA'25aq: monoclinic prisms. - CuA', 2aq : pale-blue silky needles.—AgA': white needles.—EtA'. [200°]. Silky needles (from water).

Imide of the amic acid

 $C_{\nu}H_{\nu}(SO_{\nu}NH_{\nu})< SO_{\nu}>NH$. by warming CaH,(SO2NH2)2CO2Et with KOHAq (Fahlberg a. List, B. 20, 1603; 21, 242). Tables, sl. sol. cold water, v. e. sol. alcohol and ether .st. sol. cold water, v. sol. alcohol and coner.—
K.C.H.N.S.O.; deliquescent crystalline mass.—
(CaH.(SO,NH.):SCO₂:N):Ha 3 Jaq: crystals.—
Cu(O,H.N.S.O.), 4aq: minute blue needles.—
AgC.H.N.S.O.

S. Di sulpho-benzoic seid CaH.(SO,H), CO,H.

s-Di-sulpho-benzoic acid C.H. (SO₃H)₂.CO₃H. Formed by heating benzoic acid with H₂SO₄, SO₃, and P₂O₄ (Barth a. Senhofor, A. 159, 217). Hygroscopic prisms (containing xaq). Turns brown at 140°. Yields s-di-oxy-benzoic acid on fusion with potagh. The K salt forms isophthalic acid when fused with potassium formate.—K₄A''' 1½aq: needles.—BaHA'' 2aq: minute needles.—Ba₂A''', 7aq: white prisms.—Cu₂A'''₂ 8½aq.—Ag₂A''' 2aq: crystalline pp.
References.—Browo., Nitro-, Oxy-amido, and Oxy-Sulphobenzoic Acob.

Oxy-, Sulphobenzoic ac os. m-sulpho-benzoic aldehyde

C.H. (SO.H.). CHO. Sulphonic acid of bensoic aldehyde. Formed from benzoic aldehyde and fuming H.SO. below 50° (Wallach a. Wüsten, B. 16, 150; cf. Engelhardt, J. 1804, 350). The Na salt reacts with (a)-naphthylamine forming C_eH_{*}(SO₂Na).CH:NC₁₀H_{*}, and forms with sodium naphthionate C_eH_{*}(SO₂Na).CH:NC₁₂H_{*}.SO₂Na.

Yields m-sulpho-benzoic acid on oxidation .--MgA'₂ (dried at 170°).—BaA'₂ (dried at 170'). Nodules.

The salt C6H4(SO3Na).CH:NOH Oxim. crystallises in plates, v. e. sol. water, m. sol. alcohol (Kafka, B. 24, 791).

Phenyl-hydrazide. The salt CoH, (SO, Na). CH: N. NHPh crystallises in needles, sl. sol. cold water, v. sol. alcohol.

Di-phenyl-hydrazide.

The salt C₆H₄(SO₃Na).CH:N.NPh₂ crystallises

from water in plates.
SULPHOBENZOLIC ACID v. BENZENE SUL-

PHONIC ACID. SULPHO - BENZYL - SULPHAMIC C₆H₂.CH(SO₃H).NHSO₃H. The salt Na₂A" 3aq is formed from C₆H₂.CH:NOH and aqueous Na SO, (Pechmann, B. 20, 2541). It crystallises in needles and is decomposed by NaOHAq into

henzoic aldehyde, Na.SO,, and H(NII,)SO,,
(a).SULPHO-BUTYRIC ACID C, II, SO, i.e.
CH₂.CH₂.CH₂.CH(SO₂H).CO₂H. Formed from butyric acid and CISO,H; and also by the action of (NH₄)₂SO, on α-bromo-butyric acid (Hemilian, B. 6, 196, 562; A. 176, 1; Franchimont, R. T. C. 7, 27). Formed also from crotonic acid and KHSO, at 130° (Beilstein a. Wiegand, B. 18, 483). Syrup. The Ba salt is converted by PCl, into CH₃CH₂CHCl.COCl.—CaA" 2aq: PCl₃ into CH₃.CH₂.CHCl.COCl. — UaA 2aq: needles (from ether-alcohol), insol. alcohol. — BaA"2aq. S. 71 at 16°.—PbA"2aq. — CuA"4aq.

-ZnA" 5aq. -Ag,A": prisms, insol. alcohol.

a-Sulpho-isobutyric acid C,II,8O, i.e.
CMe,(SO,II),CO,H. Formed by the action of Cl.SO,OH on isobutyric acid and also by oxidation of C, H, N, SO, which is prepared by heating thio-urea with a-bromo-isobutyric acid (Andreasch, M. 8, 412).—Na₂H" ½aq.—BaA" 4aq.

Ammonium sulphite appears to convert a-bromo-isobutyric acid into an isomeride which yields BaC, H, SO, 2aq, crystallising in needles, v.

sol. water.

β-Sulpho-butyric acid CH, CH(SO,H).CH, CO.H. Formed β-chloro-butyric ether and (NII₁)₂SO₃ (II.). Got also by oxidising barium oxy-butane disul-phonate with chlorine-water (Haubner, M. 12, 547). Amorphous.—BaA" aq (H.).—BaC, H. SO, White amorphous mass, v. sol. water, almost insol. alcohol. Yields acetic acid by potashfusion.

Sulphodibutyric acid v. DI-PROPYL SULPHONE

 $\begin{array}{ccc} \textbf{DICARBOXYLIG ACID.} \\ \textbf{SULPHOBUTYRIC} & \textbf{ALDEHYDE} & \textbf{C}_4\textbf{H}_8\textbf{SO}_4 \end{array}$ 6.6. CH, CH(SO, H).CH, CHO. Got by saturating a solution of crotonic aldehyde with SO. and distilling in vacuo, afterwards distilling with steam. On neutralisation of the residue with baryta the salt BaA'₂ is got (Haubner, M. 12, 546). The barium salt is converted by hydroxylamine into (CH(NOH).CH2.CHMe.SO3)2Ba, droxylamine into (CH(NOH).CH₂CHMe.SU₂)₂15, which is reduced by sodium amalgam to (CH₂(NH₂).CH₂CHMe.SO₂)₂Ba, which on distillation with lime yields butylamine and a little CH₂CH:CH.CH.NH₂. Sodium-amalgam reduces the sulpho-butyric aldehyde to oxy-butane sulphonic acid CH₂CH(SO₂H).CH₂CH₂OH, whence NaA', which when distilled with lime gives a minimum of butil and actual alcohols. mixture of butyl and crotyl alcohols.
SULPHOCAMPHORIC ACID v. CAMPHORIC

SULPHOCAMPHYLIC ACID v. CAMPHORIC ACID.

SULPHO-CHLORO BENZOIC AAID

CHLORO-SULPHO-BENZOIC ACID.

o-SULPHO-GENDAMIC ACID.
o-SULPHO-GENDAMIC ACID.
C₈H₁(SO₃H).CH:CH.CO₂H. Formed, together with the p-isomeride, by the action of SO₃ or fuming H₂SO₄ on cinnamic acid (Marchand, J. pr. 16, 60; Herzog, J. pr. 29, 51; Rudneff, A. 173, 8). Prisms (containing 3aq), v. c. sol. water and obselved Violence acid acid acid. and alcohol. Yields m-oxy-benzoic acid on fusion with potash.—K,A": amorphous, v. sol. water.—KHA": groups of needles.—CaA" 1½aq.

-BaH_A", S. '45 at 20°.—BaA" 1½aq. S. 4.2 at 16°. - Ag.A".

m-Sulpho-cinnamic acid [1:3] C.H.(SO.H).CH:CH.CO.H. Formed from m-sulpho-benzoic aldehyde, NaOAc, and Ac.O (Kafka, B. 24, 791).—BaA": nodules, v. sol. water, sl. sol. alcohol.

p-Sulpho-cinnamic acid p-suppn-cannamic acta [1:4] C₈H₄(SO₃H).CH:CH.CO₂H. Formed as above. Monoclinic prisms (containing 5aq). Yields p-oxy-benzoic acid by potash-fusion.— K₂A" ½ aq. Nodules (from alcohol). Reduces KMnO₄ in the cold (Liebermann, B. 22, 782).— CaA" ½ aq.—BaA" 3aq.—S. (of BaA") ·12 at 20°.—BaA" aq.—S. ·4 at 18°.—CuA" 6aq: greenish-prismus yeel water. prisms, v. sol. water.

C.H.(SO,NH,).CH:CH.CONH, Amide[218°]. Needles, v. sol. hot water (Palmer, Am. 4, 163).

Amic acid C_aH₁(SO₂NH₂).CH:CH.CO₂H.
S. 058 at 21°. Formed by heating the amide with NaOIIAq. Needles (from water), sol. alcohol, sl. sol. ether. Decomposes at 250°. Yields CaA'₂ aq and BaA'₂ 2aq, both crystallising in needles.

needles.

SULPHO-CUMINIC ACID C₁₀H₁₂SO, i.e.

C₆H₄Pr(SO,H).CO₂H [4:3:1]. [160°]. Formed
by sulphonating cuminic acid (Widman, B. 22,
2276). Crystalline.—BaA" aq: sl. sol. water.—
BaH₂A"₂ 4'₃nq. Prisms, m. sol. water.

Chloride C₆H₄Pr(SO,Cl).COCl. [56°].

Amide C₆H₄Pr(SO,NH₂).CONH₂. [225°].

Tables, sol. hot water.

Tables, sol. hot water.

Amic acid C,H,Pr(SO,NH,).CO,H. [246° cor.]. Formed by heating the amide with KOHAq at 100°. Formed also by oxidising (B)-cymene sulphonic amide [148°] with chromic acid mixture, an isomeric change taking place (Remsen a. Day, Am. 5, 158). Needles, sol. hot water. Yields BaA', 3aq, v. e. sol. water.

Sulpho-n-cuminic acid C₆H₃Pr(SO₃H).CO₂H [4:3:1]. Formed by sulphonation of n-cuminic acid (W.). V. sol. alcohol,

Chloride C₆H₃Pr(SO₂t), COOH₂. [203°].

Table (tree set) Tables (from water).

Amic acid C.H.,Pr(SO,NH.).CO.H. [216° cor.]. Formed from the amide (W.), and also boty. Foliation of p-di-n-propyl-benzene sulphonic amide [103°] (Remsen, Am. 5, 158). Long needles (from water).—CaA'₂ 6aq.—CuHA'₁ 2aq. Long -AgA': flocculent pp.

Sulpho-cuminic acid. Amic acid

C₆HMe₂(SO₂NH₂).CO₂H [5:3:2:x:1]. Formed by oxidation of isodurene sulphonic amide by alkaline KMnO, (Jacobsen, B. 15, 1855). The K salt is amorphous.

Sulpho-cuminic acid. Amic acid C.HMe.(SO,NH2).CO,H [6:4:2:x:1]. Formed by oxidation of the corresponding isodurene sulphonic amide (J.). The K salt is crystalline.

Reference.—Oxy-sulpho-cuminic acid.

SULPHO-CYANIC ACLD v. vol. ii. p. 303.

SULPHOCYANO-ACETIC ACID C.H. NSO. i.e. Cy.S.CH2.CO2H. Formed from potassium sulphocyanide and sodium chloro-acetate (Claesson, B. 10, 1347). Thick oil, changing to a solid polymeride when heated.—NaA aq: prisms. Converted by AgNO₂ into HS.CH₂.CO₂Na. CuSO₄ Gonversed by Agrica metric 15.512,002,1a. cabout forms, after a time, a black pp. of cuprous thioglycollate. — KA' aq. — BaA'2 4aq: tables. — BaA'2 aq: prisms.—CaA'2 2aq.—MnA'2 2aq. —Ethyl ether EtA'. (225°). S.G. 1:174. Formed by boiling chloro-acetic ether with potas-

sium sulphocyanide (Heintz, A. 136, 223). Liquid. Yields thioglycollic acid and thioglycollic ether on distillation with phosphoric acid. Polymerised by repeated distillation, many other products being formed at the same time. Boiling dilute HClAq forms NH2.CO.S.CH2.CO2H MeA' [75°-80°] and CaA' 2aq, and is resolved by heat into cyanic and thioglycollic acids (Nencki, J. pr. [2] 16, 11). Et lat 120° forms ethyl sulphocyanide and iodo-acetic acid.

Isoamyl ether C₃H₁₁A'. (255°).

Amide CH₂(S.CN).CONH₄. Needles.

Polymeride (C₃H₃SNO₂)₃. [200°]. Formed from potassium sulphocyanurate and potassium sulphocyanurate and potassium chloro-acetate (Claesson, J. pr. [2] 33, 121; B. 14, 732). Needles, sol. alcohol and ether. Decomposed by HClAq at 100° into thioglycollic acid and cyanuric acid.—Ba,A'', aaq: small prisms, nearly insol. water.—BaHA''' 2aq: large prisms.—Et,A'''. [81°]. Formed by distilling sulphocyano-acctic ether. Needles, nearly insol. hot water.

Persulphocyano-diacetic acid

C₂N₂S(S.CH₂.CO₂H)₂. [177°]. Formed from sodium chloro-acetate, iso-persulphocyanic acid, and KOHAq (Klason, J. pr. [2] 38, 381). Plates.

—BaA" 3aq.—CaA" 3¦aq.—ZnA" aq.—CdA".—
CuA" 6aq.—Et_A". Öil.

Amide. [125"]. Prisms.

SULPHOCYANO-ACETIC ALDEHYDE

 $CH_2(SCy).COH.$ [below -20°]. S.G. 12 1.47. Formed by heating iodo-acetic aldehyde with AgSCy and ether (Chautard, A. Ch. [6] 16, 193; C. R. 106, 1169). Oil, miscible with alcohol Decomposed by distillation, by and other. treatment with Cl, and by HClAq. HNO, forms acetic acid, sulphocyano-acetic acid, and thiocarbimido-acetic acid [128°]. Resinified by alkalis.

SULPHOCYANO-ACETONE C.H. NSO i.e. CH, CO.CH, SCy. S.G. 2 1.2; 20 1.18. S. 7 at 15°. Formed from chloro-acetone and barium sulphocyanide (Tschnerniac, C. R. 96, 587; B. 16, 349; 25, 2607, 2623). Liquid, v. e. sol. ether, v. sl. sol. ligroin. Decomposed by heat. Dissolves in aqueous KHSO₃. Boiling dilute Dissolves in aqueous KHSO. Boiling dilute HCIAq converts it into oxy-methyl-thiazole. Ammonium sulphocyanide forms 'propimine sulphocyanide' CH,-C(NH).CH,SCy '42°] (231°), which yields B'₂H,PtCl_{*}, B'HNO_{*} [183°], B'H,SO, 2aq, B'HSCy [115°], B'MeI [160°], and CH,-C(NAc).CH,SCy [134°].

Oxim CH, C(NOH).CH, SCy. [135°]. Yellowish prisms (Arapides, A. 249, 18). Produces great irritation on the skin.

SULPHOCYANO-ACETOPHENONE v. PHEN. ACYL SULPHOCYANIDE

SULPHOCYANO-BARBITURIC ACID

C₅H₃N₅SO₃ i.e. CO ${\stackrel{\rm N\,II.CO}{\rm N\,H.CO}}$ CH.SCy. Formed from di-bromo-barbiturio acid and alcoholic KSCy in the cold (Trzeinski, B. 16, 1058). The free acid splits up into thiodialuric acid and other products. Hot KOHAq also forms thiodialuricacid.—NH, A'. -KA'; tables (from water).

-AgA': crystalline pp.

-Y-SULPHOCYANO-BUTYRICACID. Nitrile. CH₂(SCy).CH₂CH₂CN. (c. 195° at 40 mm.). Formed by boiling potassium sulphocyanide (1 pt.) with γ -chloro-butyronitrile (1 pt.) and alcohol (Gabriel, B. 23, 2190). Liquid. Partially decomposed by distillation under atmo-

sandy decomposed by distinguish thinds atmospheric pressure. Converted by cone. H₂SO₄ into S_{*}(CH_{**},CH_{**},CO.NH_{**}),

a *SULPHOCYANO - ISOBUTYRIC ALDE HYDE CMc₂(SCy).CHO. S.G. ²³ 1*63. Formed from a independent price of the superior of the from a-iodo-isobutyric aldehyde and AgSCy (Chautard, A. Ch. [6] 16, 198). • Liquid with nauscous odour, decomposed by heat, by acids. and by alkalis.

SULPHOCYANO - ETHANE - SULPHONIC ACID C₃H₃NS₂O₃ i.e. CH₂(SCy).CH₂SO₃H. Formed from CH₂(SCy).CH₂Cl and aqueous Na₂SO₃ in sunlight (James, J. pr. [2] 26, 381). SULPHOCYANO-FORMIC ETHER

CyS.CO, Et. The compound (CyS.CO, Et) EtOH is got by mixing chloro-formic ether with ammonium sulphocyanide and alcohol (Delitsch, J. pr. [2] 10, 118; cf. Henry, J. pr. [2] 9, 464). It crystallises in prisms [41°], insol. water, v. e. sol. alcohol. Alcoholic potash forms Callin KSNO erystallising from alcohol in plates. KOHAq forms KSCy, alcohol, and K.CO... SULPHOCYANO-HEPTOIC ALDEHYDE.

Formed from iodo-heptoic aldehyde and AgSCy in ether (Chautard, A. Ch. [6] 16, 198). Yellowish liquid with fætid odour. Decomposed by heat, by acids, and by alkalis.

 β - SULPHOCYANO - PROPIONIC HYDE CH2(SCy).CH2.CHO. Formed by treating β -iodo-propionic aldehyde dissolved in ether with AgSCy (Chautard, A. Ch. [6] 16, 197). Liquid with fatid odour. Decomposed by heat, and resinified by alkalis and by mineral acids.

ω.SULPHOCYANO-TOLUIC ACID. Nitrile. CH₂(SCy).C.H.,CN. [86°]. Formed from c-cyanobenzyl chloride and KSCy in alcohol (Gabriel a. Day, B. 23, 2179). Needles. Converted by conc. HClAq at 180° into thiophthalide C.H.SO [57°]. Conc. H₂SO₄ at 30°-70° forms eyano-benzyl-mercaptan C₄H.NS [62°].

SULPHOCYANO-ISOVALERIC ALDEHYDE. Formed from iodo-isovaleric aldehyde and AgSCy in ether (Chautard, A. Ch. [6] 16, 198). Liquid, with fætid odour, easily decomposed by heat, by HClAq, and by alkalis.

SULPHO-DURIDE v. DI-DURYL SULPHONE. SULPHO-ETHYL-BENZOIC ACID. Amic acid C.H., NSO, i.e. C.H.Et(SO,NH.).CO.H. [262° cor.]. Formed by oxidising the sulphonic amide of p-di-ethyl-benzene with CrO, (Remsen s. Noyes, Am. 4, 202). Needles.—Bah' Baq.

SULPHO-FUMARIC ACID C,H,SO, i.e. CO₂H.CH:C(SO₃H).CO₂H. Formed by the action of Br or of HNO₃ on the salts of (δ)-bromo-(β)-sulpho-pyromucio acid (Hill a. Palmer, Am. 10, 409).—Ba, A''', 2xaq: v. sl. sol. water.— Ag₈A''' xaq.

SULPHO-HIPPURIC ACID C,H,NSO, i.e. C,H,(SO,H).CO.NH.CH,.CO.H. Formed from hippuric acid and SO, (Schwanert, A. 112, 59). Amorphous, deliquescent mass. Converted by nitrous acid into sulpho-benzoic acid.-BaA" aq: needles -- Pb. OA"

SULPHO-ISATIC ACID v. ISATIC ACID.

SULPHO-TRIMELLITIC ACID C.H.SO, i.e. $C_0H_1(SO_3H)(CO_2H)_3[5:4:2:1]$. Formed, together with the amic acid $C_0H_1(SO_2NH_2)(CO_2H)_3$, by oxidation of $C_0H_2Me(SO_2NH_2)(CO_2H)_2$ [2:5:4:1] by KMnO₄ (Jacobsen a. H. Meyer, B. 16, 192).— KH, A' Baq: prisms, m. sol. cold water. Potashfusion yields oxy-trimellitic acid.

SULPHO-TRIMESIC ACID. C₈H₇NSO₈ i.e. C₀H₂(SO₂NH₂)(CO₂H)₃. [x:5:3:1]. Formed by oxidation of the amic acid of o- or p-sulpho-mesitylenic acid (Jacobsen, A. 2006, 203).—KH₂A" 2aq: crystalline mass, m. sol. cold water. Conc. HClAq at 210° forms NH₃, H₂SO₃, and trimesic acid. Potash-fusion gives

oxytrimesic acid.

a-SULPHO-MESITYLENIC ACID C.H. SO. i.e. C_oH_.Me_a(SO_aH).CO₂H. Formed, together with a (β)-isomeride which yields CaA' 4aq, by which a (5)-isomerine which yields oak and, by the action of SO₂ on mostlylenic acid (Remsen a. Brown, Am. 3, 218). Yields o-oxy-mesitylenic acid on fusion with potash. By successive treatment with PCl, and NH₃ it is converted into an amide [288°].—Cah" 4aq. Less solwater than the salt of the (β) -isomeride.

Sulpho-mesitylenic acid. Amic acid. C_vH₁₁NSO₄ i.e. C_vH₂Mc₂(SO₂NH₂).CO₂II [5:3:6:1]. [262° cor.]. Formed, together with the (5,3,4,1)-isomeride, by oxidising mesitylene sulphonic amid with abrowing acid mixture or alkalim. amide with chromic acid mixture or alkaline KMnO₄ (Hall a. Remsen, Am. 2, 131; B. 10, 1040; Jacobsen, B. 12, 604; A. 206, 167). Short prisms (from water), sl. sol. hot water, sol. alcohol and ether. Decomposed by heating with conc. HClAq at 200° into H₂SO₄ and mesitylenic acid. Soda-fusion forms mesitylenic acid and m-xylene sulphonic amide [137°].-CaA', 6aq: long flat plates.—CaA', 5aq.—BaA', 8aq. S. 3·3 at 0°; 14 at 21°.—CuA', 4aq: blue needles.—CuA', 3aq.—AgA': pp.

Sulpho-mesitylenic acid. Amic acid C_eH₂Me₂(SO₂NH₂).CO₂H [5:3:4:1]. [276⁵ cor.]. Formed as above (J.). Long needles, v. sol. alcohol and ether, more sol. hot water than its isomeride. Conc. HClAq at 200° forms mesitylenic acid. Soda-fusion gives oxy-mesitylenic acid.—BaA'₂ 2aq. S. 2·05 at 0°.—CaA'₂ 2aq: prisms.—CuA', aq: blue monoclinic prisms. SULPHO.DI.METHYL.BENZOIC ACID.

Amic acid C,H,, NSO, i.e. C,H,Me,(SO,NH,).CO,H[4:2:5:1]. [268°]. Formed by oxidation of the sulphonic amide of ψ -cumene (Jacobsen a. Meyer, B. 16, 190). Long needles (from water). Yields di-methyl-benzoic acid on

(from water). Trents al-methyl-nenzois aud on heating with conc. HClAq at 210°.—KA'aq.

Sulpho-di-methyl-henzoic scid. [180°-190°].

Amic acid C₄H₂Me₂(S₀2NH₂).Oc₂H [1:2:5:3].

(a) - Sulphamine - hemimellitic acid. [238°].

Formed, together with the more soluble (\$\beta\$):so

meride, by oxidising the sulphonic amide of hemimellithene with alkaline KMnO, (Jacobsen, B. 19, 2519). Needles, sl. sol. cold water. HClAq at 150° forms sulpho-di-methyl-benzoic acid and, finally, hemimellitic acid [144° Potash-fusion yields an oxy-hemimellitic acid. -BaA', 5aq: small tables, m. sol, water.

Sulpho-di-methyl-benzoic acid. Amic acid $C_6H_2Me_2(SO_2NH_2)$ $CO_2H[1:3:5:2]$. [174°]. Formed as above. Stellate groups of minute needles. Converted by heating with HClAq into a very soluble sulphonic acid, and finally into m-xylene. Potash-fusion gives an easily soluble oxyhemimellitic acid.—BaA'₂4aq: needles.

Isomeride v. Sulpho-Mesitylenic acid. SULPHO-METHYL-TEREPHTHALIC ACID. A mic acid $C_aH_aMe(SO_aNH_a)(CO_aH)_a$ [2:5:4:1]. [295°-300°]. Formed by oxidation of ψ -cumene sulphonic amide by alkaline KMnO, (Jacobsen a. H. Meyer, B. 16, 190). Small needles (from water).—BaA" 2, aq: stellate groups of prisms.

SULPHONAMIDE v. Sulphamide, p. 567; and IMIDO-SULPHONAMIDE v. SULPHIMIDO-AMIDE,

SULPHONAMIDES. Amides of sulphonic acids. They contain the group SO, NH, attached by S to carbon.

SULPHONAMIDO- compounds v. Amic acids derived from Sulpho- compounds.

SULPHO-NAPHTHALENE-AZO- compounds v. Azo- compounds.

(' α')-SULPHO-(α)-NAPHTHOIC ACID

 $C_{11}H_8SO_3$ i.e. $C_{10}H_4(SO_4H).CO_2H.$ [235°]. Formed, together with the (β) - and (γ) - isomerides, by warming (a)-naphthoic acid with fuming H₂SO, at 70° (Battershall, A. 168, 119; Stumpf, A. 188, 1). Prisms, v. sol. water. Not deliquescent. Yields (a)-oxy-naphthoic acid by potash fusion. — K₂A" 2aq. — CaA" 3aq. — BaA" 4aq. Monoclinic crystals, sl. sol. water.
—BaH₂A"₂ 2aq: prisms, more sol. than BaA".

(β)-Sulpho-(α)-naphthoic acid. [218³-222°]. Crystalline mass, v. e. sol. water.—BaA" 3½aq:

needles, m. sol. water.—BaH₂Λ"₂ 4aq. (γ)-Sulpho-(α)-naphthoic acid. [182°-185°].

(γ)-suipno-(a)-naphthoic acid. [182"-185"], Needles, v. sol. water.—K,A".—BaA" 1½nq: m. sol. water.—BaH_AA", aq: almost insol. cold Aq. Sulpho-(a)-naphthoic acid. Nitrile C₁₀H_aCy,SO₂H. Formed by sulphonating (a)-naphthonitrile (Dutt, B. 16, 1251; Armstrong a. Williamson, C. J. Proc. 3, 43).—BaA'₂6aq: glistening plates.—KA' 3aq: prisms. Chloride of the nitrile C₁₀H_aCy,SO₂Cl. Prisms sol hangen.

Prisms, sol. benzene.
('a')-Sulpho-(β)-naphthoic acid. Formed, together with the ('8')-isomeride, by sulphonating (β)-naphthoic acid (B.; S.). Crystalline.—BaA" aq.—BaA" ω̄laq.—BaH₂A"₂ 6 laq. ('β')-Sulpho-(β)-naphthoic acid.—BaA" 2aq.

Less sol, water than the acid salt.

Reference .- OXY-SULPHO-NAPHTHOIC ACID. SULPHO- NAPHTHYL ETHYL DI-THIO-CARBONATE. The salt SO, K.C., H., S.CS.OEt, formed from potassium xanthate and diazotised naphthonic acid, crystallises from water in colourless plates, converted by boiling dilute alcoholic potash into S₂(C₁₀H₀:SO₃K)₂ (Leuckart, J. pr. [2] 41, 218). The corresponding salt from (8) naphthylumine (9) sulphylic acid swrttlings. (β)-naphthylamine (β)-sulphonic acid crystallines in small plates.

SULPHO · (B) · WAPHTHYL - PHOSPHORIC ACID SO₂H.C.₁₀H₄.O.PO(OH)₂. Formed, together with the anhydride O(PO(OH).C.₁₀H₄.SO₃H)₂, by heating potassium (B)-naphthol sulphonate (1 mol.) with PCl₂ (2 mols.) at 100° (Claus a. Zimmermann, B. 14, 1482). Decomposed by boiling alkalis into phosphate and (B)-naphthol sulphonate. The Ba salt is a white powder, sl. sol. water.

SULPHONES. Compounds of the form R.SO, R' where R and R' are attached by means of C to S. They may be formed from the corresponding sulphides and sulphoxides by oxidation with KMnO₄ (Beckmann, J. pr. [2] 17, 475). Aromatic sulphones can be prepared by the action of AlCl, on a mixture of a sulphonic chloride and an aromatic hydrocarbon (Beckurts a. Otto, B. 11, 472, 2066), and by heating a sulphonic acid with a hydrocarbon and P.O. at 200° (Michael a. Adair, B. 10, 583). Sulphones are often formed by the action of sulphuric acid on aromatic hydrocarbons. The sulphones are volatile, and are not reduced by nascent hydrogen. They are not attacked by PCl, or KMnO,. Chlorine in daylight converts di-phenyl-sulphone into chloro-benzene (1 mol.) and C₆H₂,SO₂Cl, while in sunlight it yields chloro-benzene (2 mols.) and SO₂Cl₂. Disulphones CHR(SO₂R')₂ are not attacked by alcoholic potash at 140°, while disulphones of the form R'.SO, CH2.CH2.SO, R' are converted by alcoholic potash into a sulphinic acid and an oxy-sulphone (Otto a. Rösspnnine acid and an oxy-sulphone (Otto & Nossing, B. 20, 185). The disulphones CMe.(SO_Et)_(sulphonal), CHMe(SO_Me). CHEt(SO_Et)_2 (Etg(SO_Me)_2, CMeEt(SO_Et)_2 (trional), and CEt_4(SO_Et)_2 (tetronal) are powerful hypnotics (Baumann a. Kast, H. 14, 52).

SULPHONIC ACIDS (organic). Acids con-

taining the group SO. OH united to C by S. Fatty sulphonic acids may be formed by the action of silver sulphite on alkyl iodides, the resulting ether being saponitied. Fatty sulphonic acids may also be got by boiling alkyl icdides with K.SO₃ or (NII.).SO₃Aq for a long time. Both fatty and aromatic sulphonic acids may be got. by oxidation of the corresponding mercaptans, sulphides, and sulphocyanides. The sulphonic acids of fatty acids and alcohols are formed by the action of SO₃ or ClSO₃H on fatty acids and of SO₃ on alcohols; SO₃H taking the α-position (Hemilian, A. 176, 1). Aromatic compounds readily yield sulphonic acids on treatment with SO3, with H2SO4, or with ClSO3H. As a rule not more than two SO, H groups enter a benzene nucleus. Aromatic sulphonic acids may also be obtained by the action of SO, on diazo- com-pounds. On adding NaCl to the product of sulphonation of aromatic compounds, the Na salt of the sulphonic acid frequently separates in crystalline form (Gattermann, B. 24, 2121). Nitric acid does not attack fatty sulphonic acids, while usually it nitrates aromatic sulphonic acids, although it sometimes displaces SO,H by NO. PCl, forms sulphonic chlorides which are reduced by zinc and dilute H2SO, to mercaptans. Aromatic sulphonic acids are partially converted into the corresponding amido- compounds by fusion with NaNH. In this way benzene sulphonic acid yields 15 p.c. of aniline (Jackson a. Wing, Am. 9, 75). Aromatic sulphonic acids are decomposed by superheated steam at 200°-

210° into the hydrocarbon and H.SO. (Kelbe, B. 19, 92). Hydrolysis may also be effected by passing superheated steam into a solution of the sulphonic acid containing H.SO. or H.PO. (Armstrong; Friedel a. Crafts, C. R. 109, 95). Aromatic sulphonic acids when fused with potash yield K.SO. and phenols. Fusion with KCN or K.FeCy. yields the corresponding nitriles. Fusion with sodium formate displaces SO. H by CO. H.

SULPHONIC ACIDS AND DERIVATIVES. Several inorganic acids, and derivatives of these acids, will be described here, most of which are regarded as derived from SO₂.OH.OH by replacing one OH by a monovalent radicle -- such as Cl, F, or NH₂—or as derived from SO₂.OH.H by replacing H by a monovalent radicle. A few sulphonic acids must be formulated as derived from 2(SO,,OH,OH), or 2(SO,,OH,II), by replacing 2OH, or 2H, by a divalent radicle; and one as derived from 3(SO, OH.OH), or 3(SO, OH.H), by replacing 30H, or 3H, by a trivalent radicle (v. supra). The sulphonic acids, therefore, are all looked on as compounds of the monovalent radicle SO₂OH. The term sulphonic is also frequently applied to organic acids containing this radicle; but in this dictionary such acids are described as sulpho-acids, e.g. sulpho-benzoic acid C.H.(SO.,OII)CO.H. The compositions of the sulphonic acids are expressed by the formulæ R'SO₂.OH, R'(SO₂.OH)₂, and R''(SO₂.OH)₃, where R' = NH₂,Cl,F,NO₂,NH.OH, or N(NO.OH); $R^{11} = NH$, or N.OH; and $R^{111} - N$.

AMIDOSULPHONIC ACID AND SALTS NH₂(SO₂,OH) and NH₂(SO₂,OM). These compounds are described in the article Sulphamo acid and Sulphamates (q.v. p. 567).

CHLOROSULPHONIC ACID AND SALTS CI(SO, OH) and CI(SO, OM). The acid has also been called chlorhydrosulphurous acid, monochlorosulphuric acid, sulphuric chlorhydrate or hydrochloride, sulphuric chlorhydrin, and sulphuryl hydroxyl chloride.

Chlorosulphonic acid Cl(SO,OH).

Formation.—1. By the direct union of SO₄ and HCl (Williamson, Pr. 7, 11; Baumstark, A. 140, 75; Williams, C. J. [2] 7, 804; Dewar a. Cranston, C. N. 20, 174; Michaelis, J. Z. 6, 235, 292).—2. By the reaction of PCl., POCl., or PCl., with cone. H.SO, (Müller, B. 6, 227; Geuther, B. 5, 925; Thorpe, C. J. 37, 358).—3. By distilling fuming H.SO, with P.O. in a current of HCl (Müller, Lc.).—4. By the reaction of HCl with crystallised fuming H.SO, (Beckurts a. Otto, B. 11, 2058).—5. By the action of Cl, S₂Cl., or S₂O₂Cl., with cone. H₂SO₄; or of Cl with moist SO₂ in presence of Pt at a red heat. 6. By warming S₂O₂Cl₂ with water (Billitz a. Heumann, B. 10, 602).

Preparation.—1. Three parts of the most conc. H₂SO₄ (preferably the residue from preparing SO₃) are warmed in a long-necked flask, and two parts PCl₃ are added little by little; when HCl ceases to be given off the contents of the flask are fractionated, the part boiling between c. 152²-156⁹ being believed apart.—2. Very conc. oil of vitriol, 200 parts, is mixed with POCl₃, 226 parts, the mixture is gently heated and then distilled [2(SO₂OH.OH) + POCl₃ = 2(Cl.SO₂OH) + HPO₃ + HCl] (Thorpe, Lc.).—

3. A mixture of P2O, and fuming H2SO, is distilled in a current of HCl, and the product is fractionated; this method removes all traces of P chlorides (Müller, l.c.) .- 4. Commercial crystalline fuming H2SO4 (approximately pure H₂S₂O₃).is placed in a retort connected with a good condenser, dry HCl gas is passed in so long as absorption occurs, the liquid is distilled, and the product fractionated; the yield is very satisfactory (Beckurts a. Otto, B. 11, 2058).

Properties .- A colourless liquid, furning much in air, and having a powerful, penetrating odour. S.G. $\frac{0^{\circ}}{4^{\circ}} = 1.78474$ (Thorpe, C. J. 37, 358); Michaelis (J. Z. 6, 235, 292) gives 1.776 at 18°. Boils at 15:3° at 760 mm. pressure (T., l.c.; v. also M., l.c.; Clausnitzor, B. 11, 2008; Beckurts a. Otto, l.c.; Behrend, B. 8, 1004). Ogier (C. R. 96, 616) gives H.F. [SO³ solid, HCl] = 14,400. Baumstark (A. 140, 75) found V.D. 59.3 (calc. = 58.12) (temp. is not given); Williams (C. J. [2] 7, 304) found V.D. at 216° to be 32.8; Heumann a. Köchlin (B. 16, 602) found V.D. 34.7 at 184° and 30.4 at 410°. The gas is therefore dissociated at a temperature not much above its b.-p. When CISO, OH is repeatedly heated above 158° it is partly resolved into SO Cl2; distilled, it gives SO₂Cl₂ (Williamson, C. J. 10, 97). By boiling the compound for a long time with an inverted condenser, Clausnitzer (B. 11, 2008) obtained H₂SO₄, SO₂, and Cl; Beckurts a. Otto (l.c.) heated ClSO₂OH for a long time in a sealed tube at c. 170°, and found that part remained unchanged, and that Cl and SO₂ were produced. Heumann a. Köchlin (l.c.) think that the decomposition at c. 440 is represented as follows: 2(ClSO₂OH) = $SO_2 + SO_3 + Cl_2 + H_2O$; they regard the high value obtained by Baumstark for the V.D. as due to presence of S₂O₅Cl₂ (v. also Claesson, J. pr. [2] 19, 235).

Reactions .- 1. Action of heat, v. supra. Propertics.—2. Water produces HClAq and H_SO₄Aq.
3. Hydrogen sulphide reacts at ordinary temperatures, forming HCl, S₂Cl₂, S, and H_SO₄ (Prinz, A. 223, 371).—4. Carbon distulphide, at 100°, produces HCl, SO., S, and COS. -5. Phosphorus pentoxide or pentachloride produce S20, Cl2 C. R. 96, 1146).—6. Heating with silver nitrate torms AgCl and NO. SO. OH (Thorpe, C. J. 41, 297) .- 7. Fusion with potassium sulphate forms K.S.O, and HCl; heating with sodium chloride forms HCl and Cl.SO. ONa (Müller, B. 6, 227).

8. The reactions of ClSO₂.OH, with several elements were examined by Heumann a. Köchlin (B. 15, 416).

Chlorosulphonates. The salts of Cl.SO.OH. which reacts as a monobasic acid, are formed by the reaction of the acid with metallic chlorides. It is very difficult to obtain these salts pure. When heated they form sulphates, giving off SO, and Cl; with water they decompose to chlorides and acid sulphates; and with alcohol HCl and salts of Et.H.SO, are formed (Müller, B. 6, 227). No accurate description of any salts has yet been given.

SO₂.Cl SO₂.Cl CHLOROSULPHONIC ANHYDRIDE SULPHUR OXY-

Pyrosulphuryl chloride, under SHLORIDES, p. 618.

FLUOSULPHONIC ACID AND SALTS F.SO2.OH and F.SO2.OM. Only the acid has been isolated.

Fluosulphonic acid F.SO, OH. Isolated and examined by Thorpe a. Kirman (C. J. 61, 921 [1892]). Prepared by placing pure SO, in a Pt vessel, surrounded by ice and CaCl. (for description of apparatus v. Thorpe a. Hambly, C. J. 55, 163), leading in excess of pure HF (made by heating KHF2), and removing excess of HF by passing in a stream of dry CO₂ for many hours, the liquid being kept at 25°-35°. A thin, colourthe liquid being kept at 25°-35°. A thin, colour-less liquid, with a slightly pungent smell, and fuming in air; boils at 162.6°, a little being decomposed with formation of H₂SO₄, and probably also SO₂F₂. Reacts rapidly with Pb, forming PbSO₄ and PbF₂; slowly attacks glass. Reacts violently, and sometimes explosively, with

water, forming H.SO.Aq and HFAq.
IMIDOSULPHONIC ACID AND SALTS NH(SO₂OH)₂, NH(SO₂OM)₂, and NM(SO₂OM)₂. By passing dry NH, into SO₃, H. Rose (P. 32, 81; 47, 41; 49, 183 [1834-40]) obtained two compounds, which he named sulphatammon and parasulphatammon, and to both of which he assigned the composition 2NH₃.SO₃. These compounds were examined by Jacquelain (A. Ch. [3] 8, 293 [1843]), Woronin (J. R. 3, 273 [1859]) and others; in 1875 Berglund (Lunds Universitets Arsskrift, 12 and 13; Bl. [2] 25, 455; 29, 422) showed that Rose's parasulphatanimon was diammonium imidosulphonate NH(SO2ONH4)2 and that sulphatammon was probably the triammonium salt N.NII₄(SO₂ONH₄)₂. Berglund's conclusions were confirmed, partly by Raschig (A. 241, 161 [1887]), and Mente (A. 248, 232 [1888], and partly by Divers a. Haga (C. J. 61, 943 [1892]). A full discussion of the constitution of Rose's compounds, with reference to the work of other chemists and an historical summary of researches on the imidosulphonates, will be found in the memoir by D. a. II

Imidosulphonic acid NH(SO2.OH)2Aq. This acid is known only in solution, which is obtained by suspending lead imidosulphonate in water, decomposing by a stream of H,S, and rapidly filtering from PbS. The solution gives a pp. with excess of BaOAq, soluble in HNO₂Aq; and a pp. of NH(SO₂OK)₂ with K.C₂H₂O₂Aq. The acid solution is very unstable, soon becoming changed to NH₂(SO₂OH)₂Aq and H₂SO₂Aq. (Jacquelain, l.c.; Fremy, A. Ch. [3] 15, 408; D. a. H., l.c. p. 945).

Imidosulphonates. The normal salts are of the types NH(SO₂.OM)₂ and NM(SO₂.OM)₂; besides these many basic salts have been isolated. The di-alkali imidosulphonates are prepared by mixing solutions of alkali nitrites and sulphites, dissolving the pp. which forms in water, heating this solution for some time, allowing to crystallise, and then boiling the nitrilosulphonate, N(SO₂OM), thus obtained (v. p. 601, NITRILO-SULPHONATES) with acidified water (for instance N(SO₂OK), + H₂O = NH(SO₂OK)₂ + KHSO₄);

also by heating the alkali amidosulphonates (e.g. 2(NH₂SO₂OK) = NH(SO₂OK)₂+NH₃); the diammonium salt NH(SO₂ONH₃)₂ is also obtained by the reaction of NH₃ with SO₃, CISO₂OH, SO₂O₂, or S₂O₂O₁. Most of the other di-salts are obtained by double decomposition from the alkali salts. The tri-salts

are generally prepared by dissolving the di-salts in excess of an aqueous solution of the base and crystallising. A number of mixed salts, such as N(NH₄)(SO_xO)_xBa, have been prepared, generally by double decomposition. Basic salts, chiefly of such slightly positive metals as Pb or Hg, have also been isolated. For references v. Divers a. Haga (C. J. 61, 943). The di-alkali salts give off NH_s, N, and SO₂ when heated; water reacts to form amidosulphonates amidosulphonates NH₂(SO₂OM)₂ and sulphates.
The chief imidosulphonates are those of NH₂

Ba, Ca, Hg, Pb, K, Ag, and Na; basic salts of Pb and Hg are known; mixed salts containing NH and Na, NH, and Ba, Ba and Hg, Ba and Na, Ca and Na, Hg and K, and Ag and Na have been isolated; some of the imidosulphonates also form double compounds with KNO3 and NaNO3. Full accounts of the preparation and reactions of the chief imidosulphonates are given in the memoir

of D. a. H.

NITRILOSULPHONIC ACID AND SALTS N(SO,OII), and N(SO,OM). The acid has not been isolated, and only a few salts are known.

Potassium nitrilosulphonate N(SO, OK), Solutions of K2SO3 and KNO2 are mixed in the ratio 4K2SO3:KNO2; after crystallisation occurs the mixture is heated at 100° till the crystals dissolve, a little water is added, and heating at 100° is continued for a little; on cooling the salt crystallises in well-formed crystals with The water of crystallisation is removed at 100°-110°; at a higher temperature decomposition occurs to K2SO4, (NH1)2SO4, SO4, and SO₂. The salt may be crystallised from dilute KOHAq; it is decomposed by water at 40° to

NH(SO₂.OK), and KHSO₄. Claus prepared this salt in 1871 (B. 4, 186), giving it the formula NH2(SO3K)3 and the name potassium trisulphammonate; Raschig (B. 20, 584 [1887]) showed that the salt was probably N(SO2.OK)3, and this composition was confirmed both by the earlier work of Berglund (B. 9, 252, 1896 [1876]) and by the more recent work of Divers a. Haga (C. J. 61, 943).

For description of a salt NO(SO₃K), v. Raschig (A. 241, 225); this is the trisulphooxyazotate of Claus and Raschig. R. regards it

as $(SO_2.OK)_3N < {\atop O} > N(SO_2.OK)_3$.

Sodium nitrilosulphonate N(SO2.ONa)3. Formed by passing SO, into a solution of NaNO, and Na₂CO₃ (in the ratio 2NaNO,:3Na₂CO₃. 10aq) until the solution is feebly acid to litmus (v. D. a. H., l.c.).

NITROSULPHONIC ACID NO2(SO2.OH), AND DERIVATIVES. The acid and its potassium salt have been isolated. The anhydride SO₂(NO₂).O.(NO₂)SO₂, the chloride NO₂(SO₂.Cl), and an oxy-anhydride S2O5O(NO2)2 have also been obtained.

Nitrosulphonic acid NO₂(SO₂.OH). (Nitrosylsulphuric acid SO₂.OH.O(NO). Lead chamber crystals. Nitrosyl hydrogen sulphate NO.H.SO.) This acid is produced by the reaction be-Name of the reaction between H₂SO₄ and any oxide of nitrogen except N₂O (Henry, P. 7, 135; A. Rose, P. 50, 161; Reibling, J. 1861. 152; Kuhlmann, 4. Ch. [3] 1, 116; Sestini, Bl. [2] 10, 226). It is also formed in the leaden chambers in making H₂SO₄ (first observed by Clement a. Desormes,

A. Ch. [2] 59, 329). The acid is produced by A. Ch. [2] 59, 529. Ine acta is produced by the reaction of SO₂ with NO or NO₂ in presence of water (Davy); also by burning 1 part S mixed with 2.5-3 parts KNO₂ in moist air (Girard a. Pabst, Bl. [2] 30, 531; Reinsch, N. J. P. 12, 3). The acid is best prepared by leading No, into well-cooled fuming H.SO, till the whole solidifies, and then drying over H.SO, (Weber, J. pr. 85, 425; 100, 37; Tilden, C. J. 28, 630); or by adding NO, in excess to conc. H.SO, washing the crystals with liquid NO,, and drying in a stream of dry air at 20°-30° or in vacuo (Müller, A. 122,

1; Gaultier de Claubry, P. 20, 467).
Colourless rhombic plates, melting at 73° (Tilden, l.c., gives m.p. 85°-87°), and easily remaining liquid below this temperature (Weltzien, A. 115, 213; De la Provostaye, A. Ch. [2] 73, On melting in air the anhydride (S2O5(NO.)2) is formed, and the water given off (S₂O₃(NO₃)₂) is formed, and the water given on causes decomposition of part of the acid to H₂SO, and oxages of N (Michaelis a. Schumann, B. 7, 1075; Fremy, C. R. 70, 61). With dry and C reacts to give NaHSO, and NOCl; on heating for a little HCl is given off (Tilden, l.c.). Dissolves unchanged in H.SO₄ (Döbereiner, S. 8, 239; cf. Lunge, B. 12, 1058; 21, 67). SO₂ is without action on dry NO2(SO,OH), but in presence of water, or H2SO4Aq with S.G. less than 1.55, decomposition occurs with formation of H₂SO₄, N₂O₃, and other oxides of N, according to Lunge (l.c.).

Potassium nitrosulphonate NO2(SO2.OK) seems to be obtained by the reaction of SO, on KNO2, also by adding liquid SO2 to dry KNO2; the salt cannot be prepared by neutralising the acid by KOHAq. The salt is decomposed by water (Schultz-Sellack, B. 4, 113).

Nitrosulphonic anhydride

S.O.(NO.). $[O < \frac{SO.(NO.)}{SO.(NO.)}]$. Formed by heating NO.(SO.OH) (Michaelis a. Schumann, B. 7, 1075); also by the reaction of SO. with NO in absence of O and moisture (H. Rose, P. 47, 605; Brüning, A. 98, 377); also by adding liquid NO to liquid SO, without warming (De la Provostaye, A. Ch. [2] 73, 362); by passing electric sparks through a dry mixture of N, O, and SO, or of S vapour and N.O. or NO (Morren, A. Ch. [4] 4, 293; Chevrier, C. R. 69, 136). Hard, regular plates; S.G. 2·14; melts at 217°; may be distilled unchanged at c. 360°. Decomposed by water to NO, H.SO₄Aq, and HNO₄Aq. NO₂(SO₂OII) crystallises from a solution in

OXYNITROSULPHONIC ANHYDRIDE

 $S_2O_2O(NO_2)_2$ $\left[O < SO_2(NO_2) \atop SO_2(O(NO_2))\right]$. A white, fusible, crystalline solid; formed by leading vapour of NO₂ into SO₃ till saturated. Gives S₂O₃(NO₂)₂ when heated (Weber, P. 123, 333; cf. Thorpe, C. J. 41, 297).

Nitrosulphonic chloride NO2(SO2-Cl). (Nitrosulphuryl chloride.) A white, crystalline solid; formed by the action of SO, on NOCl in absence of moisture, also by the reaction of AgNO, with SOCl₂ (Thorpe, C. J. 41, 297); dissolves unchanged in funing H₂SO₄; dissolves in conc. H₂SO₄, giving off HCl, and forming Cl(SO₂OH) on heating; decomposed by moist air or by water, giving HClAq, H₂SO₄Aq, HNO₂Aq, and NO (Weber, l.c.).

NITROSO-OXY-AMIDOSULPHONIC ACID AND SALTS N(NO.OH)(SO, OH). (Nitrosohydroxylamine sulphonic acid nyaroxyummne supponta acta N(NO)(SO₂OH)OH. Dinitroso-sulphuric acid SO(NO)₂(OH)₂ or (SO₂OH)₂(NO)₂H.) The acid has not been isolated, but the NH₄, Ba, Pb, K, and Na salts are known. These salts are de-

scribed as Nitrososulphates under SULPHATES,

p. 581.

OXY-AMIDOSULPHONIC ACID (Hydroxylamine SALTS NH(OH)(SO2.OH). sulphonic acid [Raschig]. Sulphydroxylamic acid [Claus]. Sulphazidic acid [Fremy].) The K salt of the acid is obtained by the action of water on N(OH)(SO₂.OK)₂ (v. Oxy-IMIDOSUL-PHONIC AGID AND SALTS, infra). The acid itself is known only in aqueous solutions. Two Ba salts, a K salt, and a Na salt have been isolated. The alts have been investigated by Fremy (A. Ch. [8] 15, 408), Claus a. Koch (A. 152, 336; 158, 52, 194), Raschig (A. 241, 161), and Divers a. Haga (C. J. 55, 760).

Oxy-amidosulphonic acid NH(OH)(SO...OH)Aq. An aqueous solution of this acid (the acid has not been isolated) is this acid (the acid has not been isolated) is prepared by heating an aqueous solution of N(OH)(SO₂OK)₂ (v. infra) to boiling (whereby NH(OH)(SO₂OK)Aq, H₂SO₄Aq, and KHSO₄Aq are formed), neutralising by NH₂Aq, adding BaCl₄Aq, filtering off BaSO₁, adding BaOAq to ppt. Ba(N(OH)SO₂O)₂Ba.H₂O, washing this pp., adding enough H₂SO₄Aq to ppt. half the Ba in the salt as BaSO₄, filtering, and so getting a solution of the (soluble) salt (NH(OH)SO₂O₂O₃D.Ba. solution of the (soluble) salt (NH(OH)SO...O).Ba. On now heating this solution with an equivalent quantity of H.SO,Aq (the Ba in solution must be estimated) and filtering, a solution of the acid is obtained (Fromy, modified by D. a. H.). The solution of NH(OH)(SO.OH) is fairly stable, but slowly decomposes; in presence of hot acid the decomposition is more rapid, giving 2NH2OH.H2SO4Aq and H2SO4Aq (Raschig, confirmed by D. a. H.). Oxy-amidosulphonates. The normal salts

Oxy-amidosulphonates. The normal salts are of the form NH(OH)(SO₂OM¹) and (NH(OH)SO₂O)M¹, where M¹=K or Na, and M¹=Ba; there is also a dibarium salt Ba\(\text{N(OH)}.SO₂O\)Ba.H₂O. The salts are best obtained from the solution of the soluble salt (NH(OH).SO₂O).Ba.H₂O (v. supra) by adding the equivalent quantity of a sulphate. The dibarium salt is itself prepared as described under the acid (supra); the monobarium salt is btained by decomposing the di-salt by enough H₂SO₄Aq to ppt. half the Ba, filtering, and evaporating over H₂SO₄ (D. a. H.). The oxyamidosulphonates are fairly stable; they are decomposed by heating with acid into hydroxylamine sulphate and H₂SO₂Aq; caustic alkalis produce only sulphite and hyponitrites (the latter rapidly undergo further change, giving off N₂O) (D. a. H., l.c.; v. also C. J. 61, 988 note). Basic oxides, such as CuO and Ag₂O, in presence of alkali produce sulphite, sulphate, and N₂O and at the same time the basic oxide is reduced

(D. a. H., l.c., p. 770).
Raschig's sulphasinate (A. 241, 197)
(SO₂.OK)N(OH).O.(OK)N.(SO₂.OK) may be derived from 2NH(OH)(SO, OH) by replacing 2H

OXY-IMIDOSULPHONIC ACID SALTS N(OH)(SO₂OH)₂. (Hydroxylamine disulphonic acid N(SO₂OH)₃OH (Raschig). Disulphydroxy-azic acid (Claus).) Only the potassium salt has been isolated.

Potassium oxy-imidosulphonate

N(OH)(SO, OK), 2aq (Claus, A. 158, 83; Raschig, B. 20, 584; cf. Divers a. Haga, C. J. 51, 659). Prepared by passing a rapid stream of SO₂ through well cooled KNO₂Aq made strongly alkaline by KOHAq; allowing N(SO₂OK); (v. Nitrilosulphonates, p. 601) to crystallise out, pouring off, and allowing to stand. Large, lustrous crystals; almost insol. cold water, more sol. water at 40°-60°; heated with water gives KHSO₄Aq and NH(OH)(SO₂.OK)Aq (v. supra, Oxy-AMIDOSULPHONIC ACID). Three Na salts and several other oxy-imidosulphonates have been prepared by D. a. H. (C. J. Proc. 1893-4. 61).

The salts described by Fremy (l.c.) as sulph-The saits described by Fremy (i.e., as such-azotates, and further examined by Raschig (A. 241, 211), and formulated by him as N(OH)(SO₂.OK)₂.N(OM)(SO₂.OK)₂, where M = K or Na, and N(OK)(SO₂.OK)₂.N(OK)(SO₂.OK)₂. may be regarded as derived from oxy-imidosul-

phonic acid N(OH)(SO...OH).

The oxysulphazotate of Claus (sulphazilinate of Fremy) examined by Raschig (i.c., p. 223) and formulated by him as

 $(SO_2.OK)_2N < O > N(SO_2.OK)_2$, may be looked on as derived from oxy-imidosulphonic acid by the removal of 2H from 2N(OH)(SO₂.OH)₂... M. M. P. M.

SULPHONO-DI-ACETIC ACID v. DI-METHYL

SULPHONE DICARBOXYLIC ACID SULPHONO-DI-BUTYRIC ACID

SO₂(CHEt.CO₂H)₂. [152°]. Formed by oxidation of sulphido-dibutyric acid (5 g.) in neutral solution by KMnO, (5 g.) in water (500 g.). Its ether is got from SO_{*}(CH_{**}CO_{*}Et)_{**}, Na, and EtI (Lovén, J. pr. [2] 33, 104). Octahedra. Sulphono-di-isobutyric acid

SO₂(CMe₂.CO₂H)₂. [182°-186°]. Formed by oxidising S(CMe₂.CO₂H)₂ (Lovén). Plates.— BaA" 2½aq. Groups of needles (from hot water). SULPHONO DIPROPIONIC ACID v. Di-

ETHYL-SULPHONE DICARBOXYLIC ACID. SULPHONO-DI-ISOVALERIC ACID

SO.(C,H,,CO,H). Formed by oxidation of S(C,H,,CO,H), and by the action of PrI (2 mols.) on sulphono-di-acetic ether (1 mol.) and NaOEt (2 mols.) at 120°; the product being saponified by baryta (Lovén, J. pr. [2] 33, 114).—BaA" 7aq. SULPHO-OXY-BENZOIC ACID v. Oxy-

SULPHO-BENZOIC ACID.

SULPHO-PHENYL-ACETIC ACID C,H,SO, e. CHPh(SO₃H).CO₂H. Formed by saponifying the product of the action of K2SO3Aq on a-bromothe product of the action of K.SO.4q on a-bromophenyl-acetic ether (Papilsky, J. 1880, 856). Very deliquescent mass.—Salts: K.A".—CaA".

—BaA": plates, m. sol. hot water.—ZnA".—ChPh.(SO.NH.).CO.Et. Tables, v. sol. water.—CHPh.(SO.NH.).CO.Et. Tables, v. sol. water.—CHPh.(SO.NH.).CO.Et. Tables, v. sol. water.—CHPh.(SO.4K.).CO.Et. thin plates, v. e. sol. Ag. SULPHO-PHENYL-AMIDO-ACETIC ACID. SH. NSO. aq i.e. SO.H.C.H.,NH.CH. CO.H. [185°]. Formed by heating phenol (1 pt.) with hippuric acid (1 pt.) and H.SO.4 (3 pts.) at 140° (Zehenter, M. 5, 332; 6, 528). Monoclinic prisms (containing aq); a:bx=98:1:128. Sol.

prisms (containing aq); a:b:c = 93:1:1-28. Sol.

water and alcohol. Coloured violet by FeCl3. Decomposed by HCIAq at 140° into phenol, glycocoll, and H.SO,. Aqua regia gives $C_0H_2(OH)Ol(NO_2)_2$ [1:2:3:5].—BaH.A''₂ aq.— AgHA" Saq: concentric groups of needles

p-SULPHO-PHENYL-CARBAMIC ACID The acid ether C_eH_{*}(SO_sH).NH.CO_sMe [188°] is formed by dissolving methyl phenyl-carbamate in fuming H_{*}SO_{*} (Hentschel, B. 18, 979) and also by adding NaOH to a cooled mixture of CICO₂Me and aqueous p-amido-benzene sulphonic acid (Noelting, Bl. [2] 50, 622).

SULPHO-PHENYL-GLYCOCOLL v. SULPHO-

PHENYL-AMIDO-ACETIC ACID.

m-SULPHO-PHENYL-PROPIONIC ACID C.H.SO. i.e. C₆H₄(SO₃H).CH₂.CH₃.CO₃H₄ Formed by treating bromo-sulpho-phenyl-propionic acid with sodium-amalgam (Göring, C. C. 1877, 793, 808). Yields m-oxy-benzoic acid by potash fusion.

exo-Sulpho-phenyl-propionic acid C_aH_a.C₂H₃(SO₃H).CO₂H. Formed by boiling cinnamic acid with aqueous K2SO3 for 12 hours (Valet, A. 154,62). Cinnamic aldehyde is converted by K₂SO₃ into PhC₂H₃(SO₃K).CH(OH).SO₃K, which crystallises in needles (containing 2aq) and is converted by boiling dilute H.SO, into exo-sulpho-phenyl-propionic acid (Heusler, B. 24, 1805). Crystals, v. sol. water and alcohol. Converted by boiling conc. KOHAq into cinnamic acid. Not affected by boiling dilute II.SO₁.—
KHA". S. 4 at 15°.—K.A" xaq. Efflorescent crystals.— CaA" xaq. Plates.— BaA" aq.—
K₂ZnA".—Ag.A" aq: white crystalline pp.
SULPHO-PHENYL-THIO-CARBAMIC ACID.

Anhydride C,H,NS,O, i.e. C,H, <NH,CS [183°]. Formed from phenyl-thio-carbimide and SO₃ (Magatti, B. 11, 2267). Crystals (from benzene), insol. water, alcohol, and ether. Insol. acids and alkalis. Decomposed by water at 100° into H2S, CO2, and amido-benzene p-sulphonic acid.

SULPHO-PHLORETIC ACID C.H.SO. Formed from phloretic (oxy-phenyl-propionic), acid and SO, (Nachbaur, J. pr. 75, 45). Sour syrup. — Na,A" xaq. — BaA" 3aq. — MgA" 5aq. — CAA" 4aq. Crystalline.

c.SULPHO-PHTHALIC ACID

 $\mathbf{C_{\bullet}H_{\bullet}}(\mathbf{SO_{\bullet}H})(\mathbf{CO_{\circ}H})_{\circ}[3:2:1].$ (a)-Sulpho-phthalic Formed by oxidising naphthalene (a)-sulphonic amide by KMnO, (Remsen, Am. 5, 107), and got also, in small quantity, together with the (β) -acid, by the action of fuming H₂SO, on phthalic acid (Rée, C. J. 49, 514). Minute orystals, v. sol. water, m. sol. alcohol. Soda-fusion gives c-oxy-phthalic acid.—Ba,A'''₂ 8aq. Needles, sl. sol. hot water.—PbHA'''11aq.—Ag,KA'''2aq. Ppd. by adding AgNO, to a solu-tion of the K salt (Stokes, Am. 6, 280).

Amic acid C₄H₁NSO₄i.e.

C₅H₄(SO₂NH₂)(CO₂H)₂. [155°-160°]. Formed by oxidation of naphthalene (a) sulphonic applied by alkaline KMnO. Thick needles (containing aq). At 155° it splits up into H₂O and the anhydride. Conc. HClAq at 150° forms c-sulphophthalic acid.—KHA": slender needles, v. sl. sol. cold water.—K₂A". [300°]. Amorphous, v. e. sol. water. Vields, when heated, the compound $C_{e}H_{2}(COCl) < SO_{2} N.POCl_{2} [120^{\circ}-126^{\circ}]$ whence

MeOH produces $C_0H_1(CO_2Me) < \frac{SO_2}{C(OMe)} > NH$ [144°] (Stokes, Am. 6, 274).—PbA".—AgHA": needles.—AgA". Insol. hot water. Anhydride of the Amic Acid

C_eH_s(CO₂H) SO₂NH. Formed as above. Begins to sublime at 200°, but is not melted at 240°. Its silver salt C,H,AgNSO, is converted. by MeI into $C_0H_3(CO_2H) < SO_2 > NMe [191° cor.]$.

The compound C_aH_a(CO₂Me) < SO₂ NMe [180° cor.] has also been prepared.

i-Sulpho-phthalic acid CoH3(SO3H)(CO2H)2[4:2:1]. (B)-Sulpho-phthalic acid. (7)-Sulpho-phthalic acid. [140] (when hydrated). The chief product of the sulphonation of phthalic acid or anhydride at 100 - 2000 (Loew, A. 143, 257; Rée, B. 18, 1629). Formed also by oxidation of naphthalene (B)-sulphonic amide (Remsen, Am. 5, 110) and by the action of hot HNO, (S.G. 13) on potassium di-nitro-(a)-naphthol sulphonate (naphthol yellow S) (Graebe, B. 18, 1126; Rée, C. J. 49, 516). Crystalline (containing aq), very hygroscopic, v. sol. water and alcohol, insol. ether. At 180° it yields the anhydride C₈H₈SO₆. Soda-fusion forms i-oxyphthalic acid. The K salt fused with sodium formate yields trimellitic acid. Heated with resorcin it yields fluoresceïn sulphonic acid. PCl₅ forms C₆H₃(SO₂Cl)(CO₂H)₂ [170° $C_0H_3(SO_2CI)$ $C_{CCI_2}^{CO}$ > 0 and C_0H_3CI $C_{CCI_2}^{CO}$ > 0. The mono-chloride is converted by NH, into C.H.(SO.NH.)(CO.H). [192°-202°] which crystal-

lises in plates, sol. water, alcohol, and ethor.
Salts.—KH₂A''' 2aq. Needles, v. sol. water.
—K₂HA''' ²aq.—(NH₄).HA''' 1¹₂aq. At 200° it yields $C_0H_3(SO_3NH_4) < \stackrel{CO}{CO} > NH$ [c. 300°]. Crys. 4 tallising in monoclinic prisms. - Ba, A", 2aq. Ball, A''', 5aq. S. 5 at 15°; 50 at 100°. At 250° it yields Ba(C, H, SO,), BallA''' 2aq.

s-Sulpho-isophthalic acid C,H,(SO,H)(CO,H),[5:3:1]. $[258^{\circ}].$ by sulphonation of isophthalic acid (Aronstein a. Kramps, B. 13, 489; Lönnies, B. 13, 704). Long deliquescent needles (containing 2aq). Potash-fusion yields s-isophthalic acid. KH2A'" 3aq: long needles.—K3A'" xaq: prisms. -Ba₂A''₂8aq: needles, v. sol. water. i-Sulpho-isophthalic acid

 $C_8H_3(SO_3H)(CO_3H)_5[4:3:1].$ [244°]. Formed by oxidation of m-xylene (a) sulphonic acid (Jacobsen a. Lönnies, B.13, 1556), and by oxidation of C_aH₃Me(SO₂NH₂).CO₂H (Remsen a. Iles, Am. 1, 114; Remsen a. Coale, Am. 3, 206). Hygroscopic needles (containing 2aq), v. e. sol. water. Potashneedles (containing 2aq), v.e. sol. water. Potashfusion yields (a)-oxy-isophthalic acid.—Salts:
KH_A^M' 2aq: needles, sl. sol. cold water. S.
1-59 at 26°.—K_A^M'.—CaHA'' 4jaq. Crystals.—
BaHA'' 3aq: small needles. S. 073 at 23°.
—BaHA'' 4aq.—Ba_A^M'. 3aq.
Amic acid C,H,NSO, i.e.
C,H,(SO,NH,)(CO,H),. Formed by oxidation of
C,H,SO,NH,)(CO,H),. Leg. (Remsen, B.
11, 464; 12, 1436; Am. 1, 122; 3, 209). When
set free from its salts it changes at one to the.

set free from its salts it changes at once to the anhydride C_aH₂(CO₂H) < NH [284°], S. ·45

at 10°.—KHA" aq. S. 2·3 at 26°.— K_2A'' 4aq: v. e. sol. water.— Ca H_2A'' , 2aq.— CaA'' 5aq.—Ba H_2A'' , 2aq: monoclinic tables.—BaA'' 3aq.— $Ag_4C_8H_1$ NSO $_4$: crystalline pp. (Jacobsen, B. 12,

c-Sulpho-isophthalic acid. Amic acid C₆H₂(SO₂NH₂)(CO₂H)₂[2:3:1]. Formed by oxidation of the corresponding m-xylene sulphonic amide (Jacobsen, B. 11, 902). Its acid potassium salt is sl. sol. water.

a-SULPHO-PROPIONIC ACID C3H6SO, i.e. CH, CH(SO, H).CO, H. Formed by boiling a-chloro-propionyl chloride with aqueous ammonium sulphite and also by warming propionic acid with CISO₃H (Kurbatoff, B. 6, 563; A. 173, 5). Syrup, v. sol. water and alcohol.-K,A" aq: needles (Rosenthal, A. 233, 27).—(NH.), A" aq: prisms.—BaA" 2aq. S. (of BaA") 745 at 18°.
—CaA" 2aq.—CdA" 2aq.—Ag, A": small needles. Got also by mixing propionic anhydride with SO_8 (Franchimont, R. T. C. 7, 27).

B-Sulpho-propionic acid CH2(SO3H).CH2.CO3H. [68°]. Formed by boiling B-iodo-propionic acid with an aqueous solution of (NH₄)₂SO₃. Got also by the action of ammonia-cal AgNO₃ on the compound of acroleïn with NaHSO₃ (Rosenthal, A. 233, 15) and obtained likewise by the oxidation of thiohydantoic acid NH:C(NH).S.CH,.CH,.CO.H (Andreasch, M. 6, 838; 7, 169). Hygroscopic crystals, sol. water and alcohol. Decomposes at 150°. Successive

and alcohol. Decomposes at 150°. Successive treatment with PCl₂ and with tin and HClAq converts it into sulphydro-propionic acid.

Salts.— K₂A" aq.— KIIA" aq.—Na,A" aq.—(NH₄),A" 4aq. Ethyl ether Et,A". Liquid.

Sulpho-dipropionic acid is DI-ETHYL-SUL-PHONE DICARBOXYLIC ACID.

SULPHO-PROPYL-BENZOIC ACID v. SULPHO-CUMINIC ACID.

SULPHO-ISOPROPYL-SUCCINIC ACID

CMe2(SO3H).CH(CO2H).CH2.CO2H. Got by action of HNO₃ on sulphocamphylic acid (Königs a. Hoerlin, B. 26, 2044). When heated in vacuo at 170° it splits up into water, SO, and terebic acid. Tables (containing 3aq), v. a. sol.

SULPHO-PYROMUCIC ACID C.H.SO, i.e. CH:C(CO₂H) O. Formed by dissolving pyromucic acid in cold fuming H2SO4, and got also by the action of zinc-dust and ammonia on diby the action of since as and aminoma of the formo-sulpho-pyromuoic acid (Schwanert, A. 116, 268; Hill a. Palmer, B. 18, 2095; Am. 10, 373, 409). Deliquescent prisma.—K₂A"4aq.—KHA".—Na₂A"5aq.—NaHA"aq.—BaA"4aq. Small prisms. Yields fumaric acid when heated with excess of bromine.—Salts: BaH₂A"₂, 4aq.—

BaH₂A''₂ 6aq. - CaA'' 3aq. - PbA'' 2aq. - Ag₂A''.

A mide C₅H₂SO₄(NIL₂)₂ [213°]. Crystalline. (β)-Sulpho-pyromucic acid

C.H.O(SO.H)(CO.H). Formed by sulphonation of brome-pyromucic acid and debromination of st be product by zinc-dust and NH₂ (H. a. P.).—
Salts: K₂A"2½aq.—CaA"2aq.—BaH₂A"; 3aq.
—BaA"3aq.—BaA"aq: small concentric prisms.

SULPHO - PYROTARTARIC ACID C,H,SO. i.e. C3H3(SO2H)(CO2H)2. Formed by boiling k.s. c₃L₃(100₂L)(100₂L)₃. Formed by boiling ita-, citra-, and mesa- conic acids with aqueous K,SO, (Wieland, A. 157, 34). Crystalline, v. e. sol. water.—Ca₂A'''₂7aq. Sl. sol. cold water.—SULPHO-QUINOLINE CARBOXYLIC ACID

C,H,N(SO,H).CO,H. (a)-Sulpho-cinchoninic acid. Formed by heating cinchonic acid with SO₃ or with H₂SO₄ and P₂O₅ at 180° (Weidel a. Cobenzl, M. 1,844). Triclinic crystals (contain-

cinchoninic acid. Formed at the same time as the preceding acid (Weidel, M. 2, 565) and prepared by heating cinchoninio acid (1 pt.) with H₂SO₄ (7 pts.) at 300° (Von Georgievitch, M. 8, 639). The same acid (crystallising with aq) appears to be formed by oxidation of benzylidenelepidine sulphonic acid by alkaline KMnO, (Busch a. Koenigs, B. 23, 2683). Colourless needles (containing 2aq), v. sol. hot water. Very bitter. Potash-fusion yields (3)-oxy-cinchoninic acid.—(NII₁)HA'' 2aq.—BaA'' aq.—PbA'' 4aq.

SULPHO-SALICYLIC ACID v. Oxy-sulpho-

BENZOIC ACID.

SULPHO-SUCCINIC ACID C.H.SO. i.e.

CO,H.CH,CH(SO,H).CO,H. Formation.—1. By exposing cooled succinio acid to SO, vapour (Fehling, A. 38, 285; 49, 203).—2. By boiling fumaric and maleïc acids with aqueous K₂SO₃ (Credner, Z. [2] 6, 77; Strecker a. Messel, A. 157, 15; Z. [2] 6, 459, 671).-3. From succinyl chloride and Ag2SO4 (Carius a. Kümmerer, A. 131, 167). -4. By oxidation of thio-malic acid with HNO, (Carius, A.

Properties .- Deliquescent mass, v. e. sol. water, alcohol, and ether. Yields fumaric acid

water, alcohol, and other. Yields tumaric acid when fused with potash.

Salts.—K₃A'' aq: efflorescent crystals.—
K₃A''' 2 ½aq.—K₄A'' 1½aq. Crystals.—KH₂A'''.—
K₂A''' 2 ½aq.—K₄A'' 1½aq.—(NH₄),A''' aq.—(NH₄)H₂A''' aq.—(NH₄)H₂A''' aq.—(NH₄)H₂A''' aq. crystals.—Ba₂A'''₂ (dried at 100°).
Pp.—Ca₃A'''₂ 6aq.—Pb₂A'''₂ 4aq.—Pb₂A'''₂ 3aq.—
Pb₂OA'''₂—Pb₂OA'''₂—Ag₂A'': n. sol. water.

SULPHO-TEREPHTHALIC ACID C₈H₈SO,

i.e. $C_8H_3|SO_3H)|CO_3H|_2|2:4:1]$.

Formation.—1. By heating terephthalic acid with fuming H₃SO₄ at 250° (Ascher, A. 161, 2; Schoop, B. 14, 223).—2. By oxidation of sulphontoluic acid (Remsen a. Burney, Am. 2, 410; Weber B. 25, 17:40), of a vilence subposition of the supposition of the supp Weber, B. 25, 1740), of p-xylone sulphonic acid (Remsen a. Kuhara, Am. 2, 414), and of C_sH₂Me(SO₂NH₂).CO₂H (Hall a. Remsen, B. 12, 1432; Am. 2, 56).

Properties.—Hygroscopic needles or tables. Salts.—KH,A''' jaq. Needles (Remsen L. Approxes.— Aygroscopic needles of tables. Salts.—KH_A'" & qq. Needles (Remsen a. Keiser, Am. 5, 170).—KH_A'" aq (W.).—K_A'" aq.—BaHA'" aq.—CaHA'" ½ aq.—BaHA'" ¼ aq.—BaHA'" aq.—Ba_A'", 8aq.—BaH_A''', 5aq.—PbHA'' 2 aq.—Ag,HA'''.

Amic acid C_sH_s(SO,NH_s)(CO,H)_r. Formed by oxidising p-xylene sulphonic amide with alkaline K.FeCy. (Noves a. Walker Am. a all

line K.FeCy. (Noyes a. Walker, Am. 9, 94).

Consentric needles, sol. hot water. Not melted at 310°.—KHA" ½aq. —BaA" aq: nodules.

Imide C₈H₃(CO₂H) < CO NH. [284°] (W.); [299° cor.] (N. a. W.). Formed by oxidation of C₈H₃Me(SO₂NH₂),CO₂H by KMnO₄. Short thin prisms (from ether), in. sol. cold water. AgNO₃ gives a pp. insol. HNO₃.—KC₈H₄NSO₃ aq.—BaC₈H₃NSO₃ 3aq. Scales, v. sl. sol. water.—Ag₈C₈H₃NSO₃.
SULPHO-TOLUENE DICARBOXYLIC ACID.

**SULPHO-TOLUENE DICARBOXYLIC ACID.

*Amic acid C₈H₂Me(SO₂NH₂)(CO₂H)₂(1:4:3:5].

[c. 300°]. Formed by oxidation of ψ-cumene sulphonic amide (Jacobsen a. Meyer, B. 16, 190).

Needles, sol. water, alcohol, and ether. —

BaA" 2 jaq: small prisms, sl. sol. water.

SULPHO-o-TOLUIC ACID C₈H₄SO₅ i.e.

SULPHO-o-TOLUIC ACID C₈H₈SO₈ i.e. C₈H₈Me(SO₃H).CO₂H [2:3:1]. Formed by heating o-toluic acid with H_.SO₄ (5 pts.) for 3 hours at 160° (Jacobsen a. Wierss, B. 16, 1960). Crystalline, v. e. sol. water. Potash-fusion yields o-oxytoluic acid.

Sulpho-o-toluic acid. Amic acid

C₄H₁Me(SO₂NH₂).CO₄H [2:5:1]. [243°]. Formed, together with about an equal quantity of the (2,4,1)- isomeride, by oxidation of m-xylene o-sulphonic amide by alkaline KMnO₄ (Jacobsen, B. 14, 38). Long needles, sol. alcohol, ether, and water. Potash-fusion yields the corresponding oxy-toluic acid. Further oxidised by KMnO₄ to C.H.(SO.NH.)(CO.H).

C₄L₄(SO₂NH₂)(CO_.HI)₂.
Sulpho-o-toluic acid. Amic acid
C₄L₃Me(SO₂NH_.).CO_.H [2:4:1]. [217]. Formed as above. Long needles, sl. sol. cold water, v. sol. alcohol and ether.—KA': crystals.

s-Sulpho-m-toluic acid

C₂H₃Me(SO₃H).CO₂H [3:5:1]. Formed, together with the (3,4,1)- isomeride, by sulphonating m-toluic acid with fuming H₂SO₄ at 180° (Jacobson, B. 14, 2355).

Sulpho-m-toluic acid. Amic acid C₂H₁Me(SO₂NH₂).CO₂H [3:4:1]. [248⁻]. S. 2 at 15°. Formed by oxidation of m-xylene sulphonic amide (Remsen, Am. 1, 37; 3, 205; Jacobsen, B. 11, 895). Needles (from water), m. sol. alcohol, sl. sol. ether. Potash-fusion gives (4,3,1)-oxym-toluic acid. KMnO₁ yields sulpho-isophthalic acid.—CaA'₂1!aq: small concentric needles.— BaA'₂4aq.—BaA'₂5aq.—AgA': needles (from hot water).

Sulpho-m-toluic acid. Amic acid C_bH₂Me(SO₂NH₂).CO₂H [3:2:1]. [203°]. Formed by oxidation of the corresponding m-xylenc sulphonic amide [96°] (J.). Converted by potash-fusion into the corresponding oxy-toluic acid.

Sulpho-p-toluic acid $C_6H_3Me(SO_3H).CO_2H$ [4:3:1].

Formation. — 1. By oxidation of thio-carvacrol (Flesch, B. 6, 480; Bechler, J. pr. [2] 8, 170).—2. By oxidation of cymene sulphonic acid (Remsen, Am. 2, 411; R. Meyer a. Baur, A. 220, 18).—3. From p-toluic acid and SO, (Fischli, B. 12, 616).—4. By oxidation of p-xylene sulphonic acid (Remsen, Am. 8, 264). Needles (containing 2aq). Not hygroscopic. V. sol. water, insol. ether. Decomposes at 185°—190° without melting. Potash-fusion-gives oxyptoluic acid [204°]. Conc. HClAq at 190° forms p-toluic acid.

Salts. - KHA" 3aq. - KHA" 2aq.-

K,A"1 jaq. — MgA"8aq. — MgA"7aq. — BaA"8aq.—BaA"4aq.—PbA"aq.—PbA"8aq.—PbA"8aq.—PbA"8aq.—PbA"8jaq.—Ag,A"aq.

Amide C,H,Me(SO,NH.).CONH. jaq. [218°].

Amid & C.H., Me(SO,NH.). CONH., § aq. [218°].

Amid acid C., H., Me(SO,NH.). CO., H. [267°].

Formed by oxidation of dynene sulphonic amide and of p-xylene sulphonic amide by chromic acid mixture (Remsen a. Hall, Am. 2, 50; B. 11, 229; Noyes a. Walker, Am. 9, 98). Needles, sol. cold alcohol, insol. ether, sl. sol. cold water.—

BaA'_2 2aq. — CaA'_2 4aq. — MnA'_2 5aq: needles. Probably the same amic acid [242°] is formed by oxidising p-butyl-toluene sulphonic amide by KMnO_4 (Kelbe a. Baur, B. 16, 2505). Sl. sol. water, nearly insol. alcohol.

Sulpho-p-toluic acid C₆H₁Me(SO₃H).CO.H [4:2:1]. [182°] (W.); [190°] (F.). that by oxidising thio-thymol (Fittien, A. 172, 329) and by evaporating its imide with HClAq (Weber, B. 25, 1741). Crystals (containing 3aq).—NH.HA".—MgA".—Ag.A".

Anhydride C_eH₂Mo < CO SO₂ > O. [97°]. Got by treating the acid with AcCl.

Amic acid C₆H₃Me(SO₃H).CONH₂. [186°]. Prisms (containing aq).—NH₄A'. Got from the anhydride in benzene by the action of dry NH₃.—

AgA' aq: scales (from water).

A mic acid C₀H₃Me(SO₂NH₂).CO₂H. [185°].

Got by boiling the imide with water (Weber, B. 25, 1739). Yellowish crystals. Probably identical with the preceding amic acid.—BaA'₂2aq.—AgA'.—MeA'. [145°].—EtA'. [95°].

Imide C_aH₂Me ⟨SO₂⟩NII. Mcthyl-sac-charin. 1240°]. Got from p-toluidine sulphonic acid vid C_aH₄MeCy.SO₂H, C_aH₃Me(Cy.SO₂Cl, C_aH₃MeCy.SO₃NH₂, C_aH₃Me(Cy.SO₂NH₂), C_aH₃Me(Cy.SO₂NH₂), the last body being heated (Kreis, G. P. 48,583; B. 22, Ref. 719; Weber, B. 25, 1737). Sl. sol. cold water, v. sol. alcohol, ether, and alkalis. Yields C_aH₃Me ⟨SO₂⟩NAg, whence MeI forms

 $C_cH_2Me < {SO_2 \over CO} > NMe~~[153^\circ],~~while~~EtI~~gives$ $C_cH_2Me < {SO_2 \over CO} > NEt~~[106^\circ]~(Weber).~~The imide is converted by warming with aqueous KOCl into <math>p$ -toluidine sulphonic acid.

Di-sulpho-o-toluic acid C_uH₂Me(SO₃H)₂CO₂H [2:3:5:1]. Formed by sulphonation of o-toluic acid with H₂SO₄ containing SO₂ (Jacobsen a. Wierss, B. 16, 1960). Minute needles, v. e. sol water.—×Ba₂Δ'''₂: amorphous, v. sol. water. Di-sulpho-p-toluic acid C_aH₂Me(SO₃H)₂CO₂H.

Di-sulpho p-toluic acid C.H.Me(SO.H).CO.H. Formed by heating p-toluic acid with fuming H.SO. and P.O. (Weinreich, B. 20, 982).—BaHA''' 5aq. Crystals.

Reference.-NITRO-SULPHO-TOLUIC ACID.

SULPHO-UVITIC ACID C₅H₈SO, i.s. C₄H₈Me(SO,H)(CO,H)₂ [5:6:3:1]. Formed by evaporating its amic acid with conc. HClAq (Jacobsen, A. 206, 185). Needles (from dilute H.SO₄). Potash-lusion yields oxy-uvitic acid.— KH.A" 2ac.—Ba.A", S. 3:23 at 12:5°. Needles

(Jacobsen, A. 206, 185). Needles (from dilute H.SO₄). Potash-fusion yields oxy-uvitio acid.—
KH₂A" 2aq.—Ba₂A"'₂. S. 3·23 at 12·5°. Needles.
A mic a cid C_bH₂Me(SO₂NH₂)(CO₂H)₂. A product of oxidation of mesitylene sulphonio amide with KMnO₄ (Hall a. Remsen, Am. 2, 136; Jacobsen). When set free from its salts it changes at once into the anhydride C_bH₁NSO_a [270°], S. 5 at 100°.—KHA".—BaA"-BaA" 8aq.

SULPHO-ISOVALERIC ACID C₃H₁₀SO₅ i.e. C₄H₁₀(SO₅H),CO₂H. Formed by heating isovaleric acid (1 pt.) with CISO₃H (1 pt.) at 150° (De Varda, G. 18, 91). Deliquescent crystalline mass. Its aqueous solution partially decomposes when heated .- BaA" aq .- PbA" 2aq.

SULPHOXIDES. Organic compounds R.SO.R' formed by the action of conc. HNO, on sulphides. Decomposed by heat. Reduced by Zn and H₂SO₄ and by HI to sulphides. Attacked by PCl₃, sulphides being formed. They reduce KMnO₄, being converted into sulphones. Sulphoxides containing monovalent alcohol radicles form unstable

mg monovaries acono ranteres form district compounds with HNO₃, such as Et₂SO,HNO₃ (Beckmann, J. pr. [2] 17, 475).

SULPHO-XYLENE CARBOXYLIC ACID.

Amic acid C₆H₂Me₂(SO₂NH₂).CO₂H [1:3:4:5].

[268° cor.]. Formed by oxidising ψ-cumone sulphonic amide (Jacobsen a. Meyer, B. 16, 190). Long needles, sl. sol. hot water. - KA'aq.

BaA'₂2½aq.
SULPHUR. S. At. w. 31.98. Mol. w. 63.96; probably also 191.88 and 255.84 (v. infra). probably also 19188 and 25584 (v. infra). The following data apply to ordinary rhombic S. Melts at c. 115°; different observers give from 111° to 115° (v. Helff, Z. P. C. 12, 219; Spring, A. Ch. [5] 22, 170; Kopp, A. 93, 129; Brodie, J. pr. 62, 336; Gernez, C. R. 83, 217; for m.p. at high pressures v. Hopkins, J. 1854. 48). Boils at 440° (Dumas, A. Ch. [2] 36, 83; Troost a. Hautefeuille, C. R. 76, 76, 219). Callender a. Griffiths (T. 182, 119) give 44:453° as lendar a. Griffiths (T. 182, 119) give 444.53° as within '1° of the true temperature of the vapour of sulphur boiling freely under a pressure of 760 mm.' (This determination was made with Pt resistance thermometers with great care, but unfortunately no special precautions were taken to insure the purity of the S used. For other determinations v. Carnelley's Melting- and Boiling-point Tables, 1, 11. For b.p. under different pressures from 1 to 760 mm. v. Monckman, Pr. 46, 136.) S.G. c. 2.03 (for numerous data v. The following data apply to monoclinic S. Melts at 117.4° (Gernez, C. R. 83, 217); at 120° (Brodie, J. pr. 62, 336). S.G. 1.982 (Marchand a. Scheerer, J. pr. 24, 129); 1.958 (Deville, J. 1, 365). S.V.S. 16.4. H.C. [S,O'] = 71,720 (Th. 2, 247; Petersen, Z. P. C. 8, 601). For volumes occupied at different temperatures v. Toepler (W. 47, 169). Crystallises in secondary forms of a monoclinic prism; a:b:c=1.004:1:1.004, angle $b:c=84^{\circ}$ 14'. Sol. CS₂, from which solution rhombic S crystallises out.

Insoluble sulphur is amorphous; insol. CS,; S.G. c. 2.04 (Troost a. Hautefeuille, C. R. 69, 248); S.G. after compression at 8,000 atmos. 1.9556 at 0°, 1.9643 at 100° (Spring, Bl. Acad. Belg. [3] 2, 83).

Cf. Allotropy of Sulphur (p. 609). Occurrence. — Native, in beds, in Sicily, Mexico, New Zealand, &c.; in the lava fissures of volcanic districts; in small quantities in the mud from the sea-bottom (Buchanan, Pr. E. 1891. 1). Many metallic sulphides also occur native-e.g. sulphides of Sb, As, Cu, Fe, Pb, Hg, and Zn. Sulphates occur in large quantitiese.g. gypsum, celestine, heavy spar; these and other sulphates are found in the earth's crust, in the sea, and in many river and spring waters. (For more details v. Dictionary of Applied CHEMISTRY, iii. 682.) S is a constituent of albumen, hair, feathers, horn, and some other parts of animals; it is also found in many plants. Small quantities of S compounds are found in the atmosphere near volcanoes. According to Young sulphur occurs in the solar atmosphere (Am. S. [3] 4, 356).

Sulphur has been known from very early times. The quantitative work of Lavoisier, in 1772, on burning S showed this substance to be an element, but it was not finally placed on the list of elements until after the experiments of

Gay-Lussac and Thénard in 1809.

Formation.—1. By the interaction of SO_3 and H_2S ; $2SO_2+4H_2S=3S_2+4H_2O.$ —2. By the partial oxidation of H₂S, either by incomplete combustion or by exposure of H₂SAq to a limited quantity of air; $2H_2S + O_2 = 2H_2O + S_2$. Also by the oxidation of FeS by exposure to moist air; $2\text{FeS} + 3\text{O} = \text{Fe}_2\text{O}_3 + \text{S}_2 - 3$. By distilling certain metallic sulphides out of contact with air, e.g. $3F_0S_2 = F_0S_4 + S_2 - 4$. By decomposing solution

5r65_= re,5,+5,:-4. By decomposing solution of an alkali or alkaline polysulphide by acid; e.g. CaS,Aq + 2HClAq = CaCl₂Aq + H₂S = 2S₂. Also by adding acid to solution of a thiosulphate; e.g. Na,S₄O,Aq + 2HClAq = 2NaClAq + H₂O + SO₂Aq + S. — 5. By decom-

SULPHUR. 607

posing S₂Cl₂ by water (2S₂Cl₂+2H₂O+Aq=4HClAq+SO₃+3S).—6. When sulphates, e.g. CaSO₄, are in prolonged contact with decaying organic matter (such as plant-leaves) they are reduced to sulphides, and if these come into contact with acids S is among the products of the reactions that occur. For a fuller account of some of these processes, whereby native S is probably formed, v. DICTIONARY OF APPLIED CHEMISTRY, iii. 683. For methods of forming the various varieties of S v. infra, Preparation.

Preparation .- 1. Ordinary S is dissolved in pure, dry CS,; a part of the CS, is distilled off, and the rest is allowed to deposit crystals of S. This process is repeated once or twice; the S crystals are powdered, kept in vacuo for some days to remove all CS, and then repeatedly distilled in vacuo, the middle portion of the distillate being collected each time.—2. Ppd. S is distilled several times in S₂Cl₂ to remove H compounds; the distillate is then repeatedly distilled in vacuo, the middle portion only being collected; the distilled S is finely powdered, repeatedly washed with water, dried, distilled over a few small pieces of pure Zn in vacuo (to remove traces of S_2Cl_2), and then repeatedly distilled in vacuo.—3. S is ppd. by adding HClAq to pure Na₂S₂O₃Aq, the pp. is repeatedly washed till free from chlorides, dried, distilled repeatedly, and finally distilled several times in vacuo (v. Monckman, Pr. 46, 149).

Ordinary rhombic sulphur is prepared by melting S and allowing to cool very slowly at 90° (Schützenberger, C. R. 66, 746), or by melting and throwing in a crystal of rhombic S when the liquid has cooled nearly to the crystallisation point (Gernez, C. R. 83, 217); also by crystallising from CS₂; and, in very well formed crystals, by saturating pyridine or picoline with H₂S and allowing to saand (Ahrens, B. 23, 2708).

Monoclinic sulphur is prepared by melting a considerable quantity of roll sulphur in a Hessian crucible, allowing to cool till a crust forms on the surface, piercing this crust, and pouring out the S that is still liquid; the walls of the crucible are covered with monoclinic crystals. This form of S can also be prepared by evaporating alcoholic solutions of (NH₄)₂S (Mallard, J. 1885. 383; Ruys, J. 1884. 336; Gernez, C. R. 100, 1539; 101, 312); also, along with rhombic crystals, from solution of S in boiling alcohol, benzene, &c. (Maquenne, Bl. [2] 41, 238). By melting S, and throwing in a crystal of the monoclinic form when the liquid is near the crystallisation point, the S solidifies in monoclinic crystals (Gernez, C. R. 83, 217).

Soft soluble sulphur is prepared by decomposing S.Cl., by water, or Na_S.O.Aq or a soluble polysulphide by a limited quantity of acid, or many metallic sulphides by fuming HNO, or SO.Aq by H.SAq (Weber, A. 141, 432, 180se, P. 47, 166; Deville, Ph. C. 1848, 200; Fordos a. Gélis, Ph. C. 1854, 294). This preparation is not homogeneous; it contains both soluble and insoluble S.

Insoluble sulphur (insol. in CS₂) is prepared by heating ordinary S nearly to boiling and then cooling rapidly (most easily by slowly pouring into a large quantity of cold water), rubbing the plastic mass so obtained with a glass rod, under water, till it becomes hard, and

removing soluble 8 by treatment with warm CS₂ (cf. Deville, Ph. C. 1848. 200). Insoluble 8 is generally present in 'flowers of sulphur' (which is formed by rapidly cooling vapour of S); by treating this with CS₂ the soluble S is removed, and the insoluble form remains. Soluble S becomes covered with a film of the insoluble variety by exposure to sunlight or electric light when melted (Berthelot, J. pr. 31, 396; Lallemand, C. R. 70, 182). Insoluble S is also said to be obtained by decomposing Na S2O, Aq by HClAq, dissolving the ppd. S in CHCl, evaporating, and keeping the crystals that separate for some time (for details v. Engel, C. R. 112, 866; Friedel, C. R. 112, 834). Insoluble S is also formed, mixed with the soluble variety, by the incomplete combustion of H.S or CS2; by decomposing H2S by fuming HNO2 aqua regia, Fe Cl, Aq, S2Cl2, or CrO, Aq; and by the reaction of HNO, Aq, SO,, or halogens with melted S (v. Wöhler, A. 86, 373; Vogel, J. Ph. [3] 29, 433; Schiff, A. 115, 68; Nöllner, A. 108, 19; Dietzenbacher, C. R. 56, 39). Insoluble S is also formed by decomposing thiosulphates by acid, or S2Cl2 or S2Br2 by water, &c., and washing the soft magma so obtained with C5, to remove soluble S (cf. Preparation of soft soluble sulphur, supra; and v. Weber, A. 141, 432; Rose, P. 47, 166; Deville, Ph. C. 1848, 200).

Colloidal sulphur, soluble in water, is prepared by passing H₂S into SO₂Aq at a little above 0° till all the SO₂ is decomposed, filtering, and concentrating over KOll in vacuo. The yellow solid so obtained is sol. water, but changes to ordinary S on keeping (Debus, C. J. 53, 282). According to Engel (C. R. 112, 866) this form of S exists in the solution obtained by adding 1 vol. Na₂SO₂Aq, saturated at the ordinary temperature, to 2 vols. HClAq saturated at 25°-30° and let cool to c. 10°, and filtering from NaCl that separates. This form of S has not been isolated in a state of purity.

Regarding the formation of the varieties of S one from the other, cf. Allotropy of sulphur, p. 609.

Properties.—S exists in several modifications. The chief are (1) soluble in CS_2 , (2) insoluble in CS_2 , (3) soluble in water.

1. Soluble sulphur exists in two, perhaps in three, varieties, differing in S.G., crystalline form, &c.

A. Ordinary rhombic (octahedral) sulphur is a pale-yellow, tasteless, very brittle solid. By crastallisation from CS, it forms clear, yellow, transparent, lustrous crystals; the colour becomes paler at low temperatures, until at -50° the crystals are almost colourless (Schönbein, J. pr. 55, 161); by immersion in boiling water it becomes easily powdered (Daguin, C. R. 20, 1667). The crystals are derived from the fundamental form of a rhombic pyramid; about thirty varieties are known. When held in the hand S emits a distinct adour, probably because of slight volatilisation; according to Berthelot (C. R. 100, 1826) S is wholly volatilisable at a temperature not much above the ordinary. Sis said to phosphoresce in air or O at 200° (Heurmann, B. 16, 139). When S is rubbed it becomes strongly (negatively) electrified. S is a bad conductor of heat, and a very bad conductor of electricity; the conductivity varies slightly,

SULPHUR.

according as the light is or is not allowed to fall on the S (Monckman, Pr. 46, 136). Insoluble in water; easily sol. CS₂ (data at beginning of article); also sol. C₄H₆, CHCl₈, &c. Sol. warm conc. acetic acid (Liebermann, B. 10, 866); sol. liquid SO₂ (Sestipi, Z. 1868. 718). As octahedral S changes to prismatic S near the m.p. of the former, it is evident that hot solutions of the former, in solvents which boil near to, or above, the m.p. of S must contain some prismatic S. Rhombic S slowly changes to monoclinic S when kept near its m.p. (v. p. 609, Allotropy of sulphur); the change is accompanied by absorption of heat (c. 650 g.-units for 32 grams S) and expansion of volume (v. Petersen, Z. P. C. 8, 601). According to Gernez (C. R. 83, 217), if a fair quantity of rhombic S is heated till melting begins on the surface, the interior portions change to microscopic monoclinic crystals, and the surface parts solidify again; this occurs only if the m.p. of monoclinic S (117.4°) is not exceeded. S melts to a clear yellow liquid; at c. 150° the liquid begins to darken and thicken; between 170° and 200° it is black, and so viscid that it does not pour out when the vessel containing it is inverted; at 330°-340° the liquid becomes thin, but it remains dark coloured until it boils at c. 444°. These changes are accompanied by very considerable changes in the electrical conductivity of S: the conductivity is almost constant from 270°-290°: it increases considerably up to 340°-350°, and then very rapidly up to the b.p. (v. Monckman, Pr. 46, 136). The expansion-coefficient, for each interval of 10°, decreases from 110° to 180°, and then increases gradually, but not regularly, to the b.p. (v. Moitessier, J. 1806. 27). Melted S may be cooled below 95° without solidifying (cf. Gernez, C. R. 97, 1298, 1366, 1433). For S.G., S.H., and other physical properties of S, v. beginning of this article.

B. Monoclinic sulphur, obtained by cooling molten S, forms transparent, yellowish brown needles; as obtained by crystallisation from solutions the crystals are nearly colourless. The crystals gradually become pale yellow and opaque, due to change into the rhombic form. The crystals are secondary forms of a monoclinic prism. This form of S is sol. CS₂; rhombic S crystallises from this solution; it also dissolves in alcohol, C₆H₆, CHCl₃, &c. On evaporation, crystals, both of rhombic and monoclinic S, separate (Maquenne, Bl. [2] 41, 238); monoclinic S may be recrystallised from alcoholic solution of (NH₄), S (for references v. p. 607, Preparation of monoclinic S). The change of monoclinic to rhombic S is hastened by scratching with a glass rod, or by covering with CS₂; heated to 95.1° at 760 mm. pressure, monoclinic changes to rhombic S; the change is accompanied by appearance of heat and contraction of volume (v. p. 609, Allotropy of sulphur). For S.G. &c. of monoclinic S v. beginning of this article.

C. Soft soluble sulphur (v. Preparation of soft soluble sulphur, p. 607) is only partly sol. CS,; it contains both soluble and insoluble amorphous S; it is a very pale yellow, or nearly white, soft, amorphous, magma that gradually hardens; when heated it gives off H.S (Weber, A. 141, 432; Rose, P. 47, 166; Deville, Ph. C. 1848. 200; Fordos a. Gélis, Ph. C. 1854. 294).

2. Insoluble sulphur. It is doubtful whether more than one variety of this form of S exists, or whether substances described as varieties are not merely mixtures of ordinary insoluble S with impurities.

D. Plastic sulphur is a citron-yellow. soft, caoutchouc-like, amorphous solid, formed by suddenly cooling molten S (v. p. 607, Preparation of insoluble sulphur); as prepared from ordinary S it is dark brown, but Mitscherlich (J. pr. 67, 369) found that the dark colour is caused by the presence of small quantities of fatty substances (cf. Dietzenbacher, C. R. 56, 39). The S.G. of brown, plastic S is c. 1.91 to 1.96; but the substance is not homogeneous; it contains both soluble and insoluble S. Plastic S soon hardens and becomes yellow, more quickly when broken up and rubbed with a glass rod, or when immersed in turpentine, or when heated to c. 100°; heat is given out in this change (v. p. 609, Allotropy of sulphur). For determinations of the volumes occupied at different temperatures by plastic S v.

Toepler (W. 47, 169).

E. Amorphous yellow sulphur is prepared from plastic S, or flowers of S, or the S obtained by decomposing thionates by acid, or H2S by oxidisers &c. (v. p. 607, Preparation of insoluble sulphur), by washing with warm CS, till all soluble S is removed. This variety is an amorphous, buff-yellow powder; kept under CS, it seems white; when dried and rubbed it forms a loose, flocculent powder. Insol. CS₂; somewhat sol. CHCl₃, Et₂O, and alcohol, according to Deville (J. pr. 56, 359). Unchanged at the ordinary temperature, but slowly converted the ordinary temperature, but slowly converted to crystalline soluble S at 100° (v. Berthelot, J. pr. 70, 941; 71, 364; Favre, J. Ph. [3] 24, 344; F. a. Silbermann, A. Ch. [3] 34, 447). S.G. 2-046 (v. data at beginning of this article). H.C. [S,O²] = 71,990 (Petersen, Z. P. C. 8, 601). The accounts of this variety of S vary considerably.

F. Black sulphur. When S mixed with a very little oil is thrown into a hot Pt dish, a black substance is obtained which has been looked on as a modification of S (Magnus, P. 92, 367; 99, 145; Dietzenbacher, P. 124, 644; Gross, B. B. 1879. 788; Jones, C. N. 41, 244; Keller, Bl. [2] 4, 346). Knapp (J. pr. [2] 38, 48; 43, 305) has shown that the black substance contains c. 55 p.c. S and c. 33 p.c. carbonaceous matter; K. thinks it is probably a modification of S adhering to carbonised products of the oil. This substance is said to be non-volatile above the b.p. of S; it is a lustrous, amorphous, solid, insol. CS2, alcohol, Et2O, oils, H2SO4, &c.
3. Colloidal sulphur soluble

water. This form of S is said to exist in Wackenroder's solution (the milky liquid formed by passing H₂S into SO₂Aq), and also in the solution obtained by adding HClAq to Na₂S₂O₂Aq (v. p. 607. Preparation of colloidal sulphur). This p. 607, Preparation of colloidal sulphur). This form of S has not yet been obtained free from impurities; it is a plastic, gummy, pale-yellow solid; it dissolves in water, forming a turbid liquid. By ppg. by NaCl, filtering, drying on bibulous paper, shaking with water, and repeating this treatment, Debus (C. J. 53, 284) obtained colloidal S that dissolved in water so as to form an almost clear, opalescent liquid which became quite clear on warming, and turbic

on cooling. This solution yielded ordinary S on addition of several salts; evaporation left a viscous, transparent residue; the S in solution did not diffuse through a porous membrane.

did not diffuse through a porous membrane.

Other modifications of sulphur. Various experimenters have described forms of S different from those usually recognised, but there is much doubt as to whether any of these are really distinct varieties, or merely mixtures of known varieties (v. Maquenne, Bl. [2] 41, 238; Gernez, A. Ch. [6] 3, 266; C. R. 100, 1326; Engel, C. R. 112, 866; Berthelot, C. R. 100, 1328; Brame, C. R. 101, 533, 639).

Allotropy of sulphur. The following table presents the best established allotropic forms of S:—

Insoluble in water.

Soluble in CS₂

Rhombie; S_a

Monoclinie; S_b

Amorphous, soft

Insoluble in CS₂
Plastic; S_r
Amorphous, yellow

Soluble in water. Colloidal; S.

The amorphous forms of S (soft, soluble; yellow, insoluble; and plastic, insoluble) and colloidal S have not been obtained pure; the soluble amorphous always contains insoluble, and the insoluble forms always contain soluble S; the colloidal contains S insoluble in water (cf. Magnus, J. pr. 70, 215; 72, 48; Weber, J. pr. 70, 354). It would probably be more accurate to make only three divisions of amorphous S: soluble in water, insol. water but sol. CS2, insol. both water and CS. Berthelot (J. pr. 71, 364; 78, 244) holds that there are two main varieties of S: soluble in CS, and insoluble in CS, separated from compounds wherein it acts as the positive radicle, or part of the positive radicle (e.g. S₂Cl₂, SO₂Aq), is insoluble, according to B.; whereas when separated from compounds wherein it forms the negative radicle, or part of the negative radicle (e.g. H₂S, K₂S), S is soluble in CS₂. B. distinguishes the two varieties of S as electro-positive and electro-negative. Cloëz (J. pr. 74, 266; 78, 241) asserts that insoluble S is obtained from S.Cl., when this compound is rapidly shaken with water, but that soluble (crystalline) S separates from the same compound by the gradual action of moist air; and that insoluble S is obtained by electrolysing H.SAq provided the electrolysis is rapid (cf. Weber, P. 141, 432).

Any form of S changes gradually to the rhombic crystals (S_a); this change is hastened by raising the temperature within certain limits. Berthelot (J. pr. 71, 360) examined the amount of soluble (crystalline) S changed to insoluble at different temperatures; he found that rhombic S heated to 130° 140° and rapidly cooled was still wholly soluble in CS_a, that much insoluble S was formed by heating to c. 170°, and not much more at c. 230°. These results can be taken only as very roughly approximate, on account of difficulties in cooling, &c. (cf. Deville, J. pr. 56, 365; Frankenheim, J. pr. 54, 436). According to experiments of Gernez (C. R. 97, 1298, 1366, 1433; 100, 1343, 1882), Ruys (R. T. C. 8, 1), and Reicher (J. 1885, 247), monoclinic S(B_g) changes to rhombic (S_g) in c. 12 days at — 36° Vol. IV.

to -15°, and in c. 80 minutes at 40°. Reicher (R. T. C. 2, 246; Z. K. 8, 593) says that the temperature of change of S_s to S_s is 95.6° at the ordinary pressure, and rises 05° for each increase of 1 atmosphere pressure; at 96:1° S. changes to S., and at 95:1° S. changes to S.. The change of any form of S to rhombic crystals is accompanied by the appearance of heat and contraction of volume; the data for the heats of combination of Sa, SB, and amorphous insoluble S give c. 650 gram-units as the quantity of heat produced when 32 grams Ss change to S., and c. 900 gram-units for the change of 32 grams insoluble amorphous S to S. (cf. Berthelot, C. R. 70, 941; and Mitscherlich, P. 88, 328). By keeping S molten for some time at 100°, and then inducing crystallisation by dropping in a crystal of S, either rhombic or monoclinic crystals can be obtained, according as the crystal dropped in is rhombic or monoclinic. When rhombic S is melted and allowed to cool under ordinary conditions the solid contains both S, and S_s; if the cooling is rapid, some amorphous S (both soluble and insoluble) is also produced; hence ordinary 'flowers of sulphur,' formed by rapidly cooling S vapour, contains both soluble and insoluble S, and generally also, when freshly prepared, both rhombic and monoclinic crystals. The crystals of S that separate from solutions in CS, are rhombic; both forms of crystals separate from solutions in alcohol, OaHa, CHCla, &c.; and monoclinic crystals separate from solutions in alcoholic (NH4)2S. Light brings about the change of soluble into insoluble S; if bright sunlight, or light from the electric arc, falls on molton Sat c. 130°, a film of insoluble S is produced. Similarly, light concentrated by a lens and directed on to a conc. solution of S in CS, quickly causes the formation of a speck of insoluble S, which soon increases in size till the liquid becomes turbid (Berthelot, J. pr. 31, 396; Lallemand, C. R. 70, 182). No differences have been observed between the chemical behaviour of the soluble and insoluble varieties of S (v. Schmitz-Dumont, B. 25, 2659).

Atomic weight of sulphur. The at w. of S has been determined (1) by converting AgCl into Ag,B (Berzelius, P. 65, 319 [1845]; Svanberg a. Struve, J. pr. 44, 320 [1843]; (2) by reducing Ag,SO, to Ag by H (Struve, A. 80, 203 [1851]; Stas, Stas R. 125 [1860]); (3) by direct synthesis of Ag,S (Dumas, A. Ch. [3] 55, 147 [1859]; Stas, Stas R. 53 [1860]); (4) by determining S.H. of S (Kopp, T. 1865, 71); (5) by determining V.D. of, and analysing, SH, SO, S,Cl., &c.

Molecular weight of sulphur. The V.D. determinations of Dumas (A. Ch. [2] 50, 170) gave c. 95 at 450°-500°, pointing to the molecular formula Se,; Bineau (C. R. 49, 799) found V.D. 39 from 714° to 743°, and 34 between 840° and 1160°, indicating the molecular weight S_s. chemical behaviour of the soluble and insoluble

Molecular weight of sulphur. The V.D. determinations of Dumas (A. Ch. [2] 50, 170) gave c. 95 at 450°-500°, pointing to the molecular formula S₄; Bineau (C. R. 49, 799) found V.D. 39 from 714° to 743°, and 34 between 840° and 1160°, indicating the molecular weight S₄. The determinations by Deville a. Troost (C. R. 56, 891) at 860°-1040° confirmed the number 32 and the molecular weight S₄. Troost (C. R. 95, 30) got the number 42·5 at 665°, indicating a mol. w. of c. S₄ (V.D. corresponding to S₄—48). In 1888 Biltz determined V.D. of S at intervals from 468° to 606°, and got results ranging from 113·2 at the lower temperature to 68·4 at the higher (S₇=112; S₄=64). The V.D. constantly decreased as temperature rose; the V.D. was constant only between 502° and 524°, but the

values were between those calculated for S, and S. Biles concluded that the only molecules which exist as gas through any considerable range of temperature have the composition S2. Ramsay (Z. P. C. 3, 67 [1889]) thought that Biltz's results did not negative the existence of gaseous molecules more complex than S2. Schall (B. 23, 1701 [1890]) got numbers for V.D. varying from 115 to 122, at 573° and pressures from 10-20 mm., in an atmosphere of N or CO.; S. concluded that molecules S, probably exist in the vapour of S. Riecke (Z. P. C. 6, 430 [1890]) regarded the decrease of V.D. with increasing temperature as a dissociation of S, to S, and S,; by making certain assumptions, his calculated results agreed well with the experimental numbers of Biltz. In 1888 Paterno a. Nasini (B. 21, 2153) determined the depression in the freezing-point of benzene caused by dissolving S therein; their results indicated S_a as the molecular for-mula of S in solution in benzene. By determining the increase in the boiling-point of CS, produced by dissolving S in that solvent, Beck-nann (Z. P. C. 5, 76 [1889]) got values for the mol. w. of S varying from 245 to 280 (S_a = 256). Sakurai also used this method in 1892 (C. J. 61, 989); his values for mol. w. of S in CS, varied from 252.3 to 254.9. From observations of the effect of dissolving S in naphthalene on the f.p. of the solvent, Hertz (Z. P. C. 6, 358 [1890]) concluded that the mol. w. of S in solution in naphthalene is $256 = S_s$. Helff (Z. P. C. 12, 196) in 1893 also got S, for mol. w. of S in CS2, and in molten P. These results leave little doubt that molecules S, exist in solutions of S in CS, and in naphthalene, and S, in solutions in benzene; that molecules of greater complexity than S₂—probably as complex as S₃—exist in S vapour, but these are stable only through a small range of temperature, and gradually dissociate as temperature rises until all the molecules existing above c. 700° have the composition S₂. Biltz a. Meyer (B. 22, 725 [1889]) have shown that the V.D. of S corresponds with the mol. w. S₂ up to 1600°-1700°.

Reactions.—1. Reacts with water at 100° to form H.S. Cross a. Higgin (C. J. 35, 249; B. 16, 1195) found that the solution contained thionic acids; they supposed that these were produced by reactions between the H.S and SO. formed by the action of the S on the water (cf. Payen, J. Ph. 8, 371; Mulder, J. 1858, 84; Meyer, C. R. 74, 195; Gélis, C. R. 56, 1004). Senderens (Bl. [3] 6, 800) regarded the production of H.S as due to interactions between the S and the glass vessels employed; C. a. H. (C. J. 35, 252) found H.S was produced when dilute H.SO.Aq was used in place of water, and they concluded that the alkaline constituents of the glass were without influence. Becquerel (C. R. 56, 287) says that when water containing S in suspension is electrolysed, H.SO., forms at the positive, and H.S at the negative, electrode (cf. Colson, Bl. [2] 34, 66). When S is moistened with water and let stand in the air, H.SO., Aq is said to be produced (Polacci, C. C. 1884, 484; Böhm, M. 3, 224).—2. S is oxidised to H.SO., Aq by heating with nitric acid, aqua regia, or polassium chloruric acid is reduced, giving off SO.,—4. Cone, hydriodic acid gives H₃S and I (I de-

composes dilute H.SAq to HIAq + S) .- 5. Chlorosulphonic acid when heated with 8 produces S₂Cl₂, SO₂, and HCl (Heumann a. Köchlin, B. 15, 416).—6. S dissolves in boiling alkali solutions, also in molten alkalis and alkaline car. bonates, to form mixtures of polysulphides and thiosulphates. Boiling ammonia solution forms polysulphides; heated in a sealed tube above 100° some (NH),28,0,4A is produced (v. Brunner, D. P. J. 150, 371).—7. Sulphur trioxide dissolves S, forming a blue solution of S2O3 (v. SUL-PHUR OXIDES) .- 8. Carbon dioxide reacts with boiling S to form COS (Cossa, B. 1, 117; Berthelot, Bl. [2] 40, 364). The same compound is produced by volatilising S, by an electric current, in carbon monoxide (Chevrier, C. R. 69, 56) .- 9. PSCl. is formed by the interaction of S and phosphorus trichloride at 180° (Henry, Bl. 13, 495). Phosphorus pentachloride forms PCl. and S.Cl. (Goldschmidt, C. C. 1881. 489). 10. S decomposes many sulphates and carbonates at high temperatures, forming sulphides and SO₂, or CO₂ (v. Sestini, Bl. [2] 34, 490; Berthelot, Bl. [2] 40, 364).—11. Solutions of salts are very often reduced by boiling with S, sulphides being generally ppd. (v. Vortmann a. Padberg, B. 22, 2642; and, more fully, Senderens, Bl. [3] 6, 800; 7, 511).

Combinations.—1. Sulphur combines directly with most of the elements. The binary compounds of S—with the exception of those with Br, Cl, F, I, or O, and also compounds of S with more than one other element (except these be some of the five just mentioned)—are described under the least negative of the component elements; e.g. compounds of S with P and Cl are described (as sulphochlorides) under Phosphorus. For the conditions of formation of the binary compounds of S reference must be made to the various elements, except in the cases of bromide, chloride, fluoride, iodides, and oxides of S, which are described in this article in their proper (alphabetical) places.—2. Chlorine monoxide Cl,O is said to combine directly with S (suspended in S,Cl₂), at -12°, to form SOCl₂ (Wurtz, C. R. 62, 460).

Sulphur, acids of. Reference should be made to Hydrogen sulphide, vol. ip. p. 725; Sulphur oxyacids, this vol. p. 619; Sulphur oxyacids, nitrogen derivatives of, this vol. p. 619; Sulphogranic acid, vol. ii. p. 303; Sulphomo acids and derivatives, this vol. p. 599; Thiocarbonic acid, vol. i. p. 703. For acids, and salts of acids, containing S and P, and S, P and O, v. Phospidores sulphides, this vol. p. 145 (beginning of article); also Phosphorics sulphide, Reactions 7 and 8 (p. 146), Phosphoric sulphide, Reaction 8, and also end of that article (p. 147).

Reaction 8, and also end of that article (p. 147). Sulphur, bromides of. It is very doubtful whether any definite compound of S and Br exists. Powdered S dissolves in Br with evolution of a little heat; the deep ruby-red liquid begins to distil over at c. 60° and the thermometer rises steadily to c. 190°, when it secends slowly to c. 200°, after which it steadily rises till S remains; the fraction coming over at 190°-200° agrees fairly in composition with the formula S₂Br₂ (Pattison Muir, Ö. J. 28, 845). M. found that by passing CO₂ through a solution of S in excess of Br for some hours, at 15°, 50°, and 90°, the residual liquid had nearly the com-

position S.Br₂; Hannay, however, by passing air through such a liquid for 400-500 hours found that the whole of the Br was removed and that pure S remained (C. J. 33, 284; 35, 16). It is, however, possible that at the temperature of this experiment, c. 15°, dissociation of S.Br. was induced by the stream of air. H. also found that the vapour given off by the supposed S.Br., even at 0°, showed the absorption-spectrum of Br. Spring a Lecrenier (Bl. [2] 45, 867) examined the reaction of the supposed S₂B₂ with K₂SO₃. S. had before shown that S₂Cl₂ and K₂SO₃ produce KCl and K₂S₄O₄; but Cl and S acting as free elements produce K₂SO₄, KCl, K₂S₂O₃ and SO₄. S₂Br₂ ought then to produce KBr and K₂S₁O₅, whereas S and Br would form K.SO., KBr, K.S.O., and SO.; by determining the quantities of the products S. a. L. calculated that the supposed S.Br. contains c. 27 p.c. of the elements uncombined. Various reactions of the supposed S2Br2 are described in the memoirs already referred to (v. also Rose, p. 44, 327; Michaelis, J. Z. 6, 297; Ogier, C. R. 92, 922).

Sulphur, chlorides of. Three compounds of S and Cl are known: S₂Cl₂, SCl₂, and SCl₄. These compounds are liquids; S₂Cl₂ boils unchanged at c. 138°, SCl₂ begins to decompose to S₂Cl₂ and Cl at c. 10°, and the decomposition of SCl, to SCl, and Cl begins at c. - 20°.

Suiphur Monochioride S.Cl., (Sulphur protochloride, Sulphur sulphochloride, Sulphur thionyl chloride, Thio-thionyl chloride.) Mol. w. 134.7. Boils at 138.12°; S.G. 42 1.70941, S.G. at b.p. 149201 (Thorpe, C. J. 37, 356). S.V. 90.28 (T., l.c., p. 372). V.D. 68-4 (Dumas, A. Ch. [2] 49, 204; Marchand, J. pr. 22, 507). $\mu_{\rm in}$ = 1·64449 (Haagen, P. 131, 117). H.F. [S^{*},Cl^{*}] (from S_s) = 14,257 (Th. 2, 310); 17,600 (Ogier, C. R. 92, 922).

Formation .- 1. By the interaction of S and Cl.-2. By distilling S with 9 parts SnCl, or 8.5 parts HgCl₂.—3. By reacting on PCl, with S (Goldschmidt, C.C. 1881, 489).—4. By decomposing PSCl₂ by Cl or by heating to redness.—5. By the interaction of P₂S₂ and SOCl₂, the other product being P_2O_3 (Carius, A. 106, 331). – 6. By the action of CS_2 on ICl_3 (Weber, P. 128, 459).

Preparation.—A stream of dry Cl is passed into a flask, or retort, containing S (flowers or sticks) until most, but not quite all, S is dissolved to a yellowish red liquid, the vessel being gently warmed. The liquid is repeatedly distilled until it boils constantly at 138°-139°. If the passage of Cl is continued until the S is completely dissolved, the liquid must be distilled from a little 8 (to decompose SCl, quickly).

Properties. - A yellowish-red, oily liquid, with a very characteristic, rather disagreeable, odour and an acid taste; the vapour affects the mucous membranes rapidly, causing tears, and affecting the breathing. Does not become viscid at -75° (Haase, B. 26, 1052). Fumes in air. Dissolves in CS, and C,H, also in alcohol and ether with decomposition. S,Cl. dissolves large quantities of S; solution of S,Cl., containing free S, in CS, is used for vulcanising (v. Dictionary or APPLIED CHEMISTRY, vol. iii. p. 706).

SO,Aq, and S, with a little H,SAq, H,S,O,Aq, and some of the thionic acids.—2. Bydrogen sulphide produces HCl and S; hydrogen iodide reacts at the ordinary temperature to form HOl, I, S.I., and then H.S (Hautefeuille, Bl. [2] 7. 198). - 3. By passing S.Cl., vapour, mixed with and Cl are formed (Donny a. Mareska, C. R. 20, 817; Spring a. Lecrenier, 18. [2] 45, 867). A. Heating with phosphorus produces PCl_s, PSCl_a and S if a little P is used; or PCl_s, P sulphides, and red P if much P is used (Wöhler a. Hiller, A. 93, 274; Chevrier, C. R. 63, 1003) .- 5. Heated with many metals, S.Cl. gives metallic chlorides and S; the more volatile the metallic chloride the more readily does the reaction occur (v. Chevrier, C. R. 64, 302).-6. S.Cl. combines with chlorine, forming SCl. and SCl. (q.v., infra). Br and I are absorbed by S.Cl.; according to Evans a. Ramsay (C. J. 45,65) no compound is formed with Br. -7. With oxides of arsenic and antimony S.Cl. forms AsCl, and SbCl, giving off SO, and separating S; selenion dioxide produces Sc.Cl, and SO, oxides of phosphorus, boron, and silicon do not react (Prinz, A. 223, 355).—8. S₂Cl₂ absorbs sulphur trioxide, below 0°, forming a brownish-yellow liquid, from which excess of SO, crystallises out; a little above 6" SO, is given off, rapidly at 10°; S.O.Cl. is formed on distillation (Rose, P. 44, 291) .- 9. By passing vapour of S2Cl2 along with the vapours from sulphonic acid through a hot tube, SO., H.S., S. HCl, and Cl are produced (Brault a. Poggiale, J. Ph. 21, 140) .- 10. Heating S₂Cl, with sulphates generally produces SO,Cl₂ chlorides, S, and SO₂; heated with sulphuryl chloride to 250°, S,OCl, is formed (v. Schneider, J. pr. 104, 83; [2] 33, 18; Demarcay, C. R. 92, 720, 111, S,Cl, combines with supersystems 720).—11. S.Cl. combines with anumonia gas to form S.Cl. 4NH, stable in air, sol. alcohol, decomposed by water giving NH,ClAq, (NH,),S,O,Aq, and S (Brault a. Poggiale, J. Ph. 21, 140) .- 12. Reacts with organic compounds containing oxygen, generally forming Cl compounds and small quantities of S compounds, and also HCl, SO, and S .- 13. Combines with unsaturated hydrocarbons; e.g. with C.H. forms $\mathbf{C}_{2}\mathbf{H}_{4}\mathbf{S}_{2}\mathbf{Cl}_{2}.$

SULPHUR DICHLORIDE SCl. Mol. w. (in solution in benzene or acetic acid) 102.72. S.G. tion in benzene or acetic acid 102°72. S.tr. 1-6482 at 15·4° (Costa, G.20, 367). $\mu_{\rm Ha}$ =1·5716 (Costa, Lc). No constant b.p. (v.infra). This compound was prepared by H. Rose in 1831 (P. 21, 431; 27, 167); the experiments of Dumas (A. Ch. [2] 49, 204) and Marchand (J. pr. 22-507) led to its recognition as a definite compound (v. also Carius, A. 106, 291); Hübber a. Gueront (Z. 1870. 455) isolated the compound satisfactorily, and their results were confirmed satisfactorily, and their results were confirmed by Thorpe a. Dalzell, in 1871 (C. N. 24, 159). Costa, in 1890 (G. 20, 367), determined the mol. w. of the compound in solution.

Preparation.-Dry Cl is led into S2Cl, surrounded by a freezing mixture, until the liquid becomes deep red; excess of Cl is removed by a stream of dry CO₂. The temperature must not rise above 6°; the vessel containing the S_cCl₂ should be kept filled with Cl continually, and of Applied Chemistry, vol. iii. p. 700).

Reactions and Combinations.—1. S₂Cl₂ sinks in water, and then decomposes, giving HClAq,

A. Ch. [2] 67, 64; Michaelis, A. 170, 1). Properties. — A thin, dark, brownish-red, liquid, with smell and taste like S.Cl.; does not solidify at -30°; gives off Cl when exposed to sunlight, and should, therefore, be kept in a sealed tube in the dark. Easily decomposed by heat to S,Cl, and Cl; Michaelis (B. 6, 995) gives a table showing amount of dissociation from 20° to 130°; the temperature whereat 50 p.c. of the SCl, is dissociated is c. 86°. SCl, reddens dry litmus paper. The depression of the freezingpoint of benzene or glacial acetic acid by solution therein of SCl2, shows that the mol. w. agrees with the formula SCl₂ (Costa, G. 20, 367).

Reactions and Combinations .- 1. Heat, or direct sunlight, causes dissociation to S.Cl., and Cl (v. supra, Properties).—2. Water produces HClAq and H.S.O.AAq.—3. Oxidised violently by nitricacid to HClAq and H.SO.Aq.—4. Ammonia solution produces N₁ClAq, N, and S; ammonia gas combines to form SCl₂2NH₃ and SCl₂4NH₃, soluble, unchanged, in absolute alcohol and ether (Soubeiran, A. Ch. [2] 67, 74).—5. Thionyl chloride (SOCl₂), when heated with SCl₂, forms S₂OCl₄(Ogier, Bl. [2] 37, 293).—6. Alkali sulphites produce chlorides and trithionates (Spring a. Lecrenier, bl. [2] 45, 867).—7. Some inetals, e.g. Cu, Fe, K, react with SCl., with production of heat and light, and formation of chlorides and sulphides.—8. Combines with arsenious chloride, forming AsCl, SCl, according to H. Rose (P. 27, 107).—9. SCl, reacts with oxygenised carbon compounds similarly to, but more readily than, S₂Cl₂; it combines with several unsaturated hydrocarbons (v. Heintz, A. 100, 370; Guthrie, C. J. 12, 109).

SULPHUR TETRACULORIDE SCI,. This compound exists only at temperatures under -20°. The molecular weight is probably 173.46 (SCl.).

Preparation.—S₂Cl₂ is cooled to below -20°

Preparation.—S₂Cl₂ is cooled to below -20° (c. -22°) and a slow stream of dry Cl is passed in until absorption of Cl ceases. Michaelis a, Schifferdecker (B. 6, 993) found that 67.5 g, S₂Cl₂ kept at -20° to -22°, absorbed 106 g, Cl in 10 cm s - 20° (c. 10 cm s). 10 hours, that absorption of Cl then ceased, and that the liquid had the composition SCl.

Properties.—A mobile, yellowish-brown liquid; when removed from the freezing mixture used in the preparation, the liquid gives off Cl, and boils with an absorption of much heat. M. a. S. give the following data showing the dissociation of SCl₄ to SCl₂ and Cl:—

Temp.	P.c. SCl	P.c. SOL
- 22°	100.0	0.0
- 15	41.95	ີ 58⋅05
- 10	27.62	72:38
- 7	21.97	78·0 3
- 2	11.93	88.07
+0.7	8 ·8 7	91·13
+6.2	2.43	97.57

Reactions .- 1. Water causes rapid decomposition to HClAq and SO,Aq, with more or less S according to the mass and temperature of the water.—2. With sulphur trioxide, in the ratio SOI:SO, the products are SOCl, and S,O,Cl, in the ratio SCI,:2SO, the products are SOCI, SO, and Cl (M. a. S., Le.; also B. 5, 924). Sulphur dioxide does not react.—8. Chlorosulphonic acid reacts at a low temperature to form S.O.Cl. and HCl (M. a. S., B. 6, 996).—4. With some hydroxylic organic compounds, e.g. C.H.OH and

C.H. CO.OH, OH is replaced by Cl and SOCL is formed.

Combinations .- 1. Compounds of SCI, with several metallic chlorides are produced by warming the chlorides with S₂Cl₂ and passing in Cl; the compounds 2AlCl₂SCl₄ AuCl₂SCl₄ and 2TiCl₄SCl₄ are formed thus (Weber, P. 104, 421; Rose, P. 42, 517; Casselmann, A. 83, 267). The compound with AlCl, may be distilled in a closed shaped tube; the other two compounds A shaped tube; the other two compounds give off Cl when heated. The compounds SbCl, 3SCl, and SnCl, 2SCl, are produced by passing Cl over SnS, and Sb, s, respectively (R., l.c.; C., l.c.).—2. With iodine trichloride forms ICl, 3Cl, (Weber, P. 128, 459; cf. Jaillard, A. Ch. [3] 59, 451, who gives the composition SCl, 2ICl, Prepared by passing Cl into I dissolved in CS, till the liquid is wine-red, cooling, and drying the red-yellow, prismatic, very deliquescent, crystals, in a tube in a stream of dry Cl. Also formed by passing Cl into a mixture of 2 pts. S and 1 pt. I. Melts to a brown liquid when heated in a closed tube: heated in an open tube forms Cl, ICl, and S2Cl2; decomposed by water or dilute HNO, Aq.

Sulphur, chloro-iodide of, SCl.I(= SCl.,ICl.): v. supra, Sulphur Tetrachloride, Combinations, No. 2.

Sulphur, chloronitride of, S.CIN; v. NITROGEN SULPHOCHLORIDE, vol. iii. p. 571.

Sulphur, cyanides of, v. Cyanogen, sul-PHIDES, vol. ii. p. 358.

Sulphur, fluoride of. According to Gore (Pr. 20, 70 [1871]) the heavy colourless gas produced by fusing AgF with S is a fluoride of S. This gas is not liquefied at 0°, at the ordinary pressure; it fumes in the air, and attacks glass; no analyses are given by G.

Sulphur, haloid compounds of. The most stable of these compounds belong to the forms S₂X₂; where X = Cl. Br, or I. The chloride S₂Cl₂ may be distilled unchanged; the bromide, S.Br., is exceedingly easily decomposed if, indeed, it has been isolated; the iodide, S₂I₂, has been very slightly examined. The compounds SCl₂ and SCl, also exists; the former at temperatures below c. 10°, and the latter below c. -20°. The compound SI_s perhaps exists; it gives up I at the ordinary temperature. The only haloid compound of S that has been gasified unchanged is S₂Cl₂.

Sulphur, hydrides of, SH2 and (?) S3H2; v. HYDROGEN SULPHIDES, vol. ii. p. 725.

Sulphur, nitride of, SN; v. NITROGEN SUL-PHIDE, vol. iii. p. 570.

Sulphur, iodides of. S and I probably combine when heated together, but no definite compound has been isolated by this method (cf. Gay-Lussac, G. A. 48, 372; H. Rose, P. 27, 115; Lamers, J. pr. 84, 349; Sestini, J. 1863. 153; Wheeler a. Lüdeking, Fr. 26, 602).

SULPHUR MONO-IODIDE S.I.. Guthrie (C. J. 14, 57) obtained this compound by placing 2½ parts ÉtI and 1 part S₂Cl₂ in a sealed tube, opening after 12 hours, evaporating EtCl by warming with the hand and removing excess of Eti by gently warming; the S.L. crystallised out in lus-trous crystals resembling I. (One analysis is given, but no full description of properties.)

Ogier (O. R. 92, 922) gives H.F. $[S^2, I^2]$ (from gases) = 10,800.

SULPHUR HEXA-IODIDE SI. This compound is said to be formed by slowly evaporating, at a low temperature, a solution of I with slight expess of S in OS₂. Grey-black crystals; resembling, and isomorphous with, I; I evaporates on exposure to air and eventually only S remains; ticohol, conc. KOHAq, or KHAq, also withdraws all I (G. vom Rath, P. 110, 116; Lamers, J. pr. 84, 349). It is very doubtful whether the crystals examined by vom Rath were a compound or only I retaining a little S.

By passing H.S into a dilute solution of KCl.ICl₃, Lamers (l.c.) obtained an orange-red pp. which dried in an exsiccator to a brown amorphous mass containing S and I in the ratio S.I..

By subliming SnS₂ with I, Schneider (J. 1860. 186) obtained a compound to which he gave the composition SnSI₂.SI₂.

Sulphur, iodochloride of, SICl, (= SCl, ICl₃) v. Sulphur tetrachloride, Combinations No. 2.

Sulphur, oxides of. Four compounds have been isolated; S₂O₃, SO₂, SO₃, and S₂O₄. S and O combine directly to form SO₂ and SO₃; S dissolves in SO₃ to form S₂O₃; S₂O₃ is formed by the action of an electric discharge on a mixture of SO₂ and O, or SO₃ and O.

SULPRUR SESQUIONIDE S₂O₃ (Hyposulphurous anhydride). The production of a blue substance, on distilling funing H₂SO₄ and S, was noticed by Buchholz in 1804 (Gehlen's J. 3, 7); Vogel, in 1812, obtained the blue body by bringing together S and SO₃ (S. 4, 121); the substance was examined by Wach (S. 50, 1), Berzelius (Lehrbuch [5th edit.] 1, 485), and Stein (J. pr. [2] 6, 172). Weber, in 1875, isolated the compound and found its composition to be S₂O₃ (P. 156, 531).

S₂O₂ is prepared by adding well-dried flowers of sulphur, little by little, to SO₂ quite free from H₂SO₄, more S being added when the previous quantity has all combined. The process is conveniently conducted in a test tube, covered with a small porcelain crucible to exclude moisture, and plunged into water cooled to c. 12°; the S disappears in the SO₂ and blue drops are formed; the tube should be tilted so that the blue drops come into contact with the sides of the tube where they form a thin crust (if the drops solidify as they float in the SO₂, the solid S₂O₂ retains SO₃, from which it cannot be freed). When c. 1g. S has been added, excess of SO₄ (which should be colourless) is poured off, the last traces being removed by gently and carefully warming not above 35°; the solid S₂O₂ is seraped out of the tube by a glass roal

(which should be colourless) is poured off, the last traces being removed by gently and carefully warming not above 35°; the solid \$,0, is scraped out of the tube by a glass rod.

\$\(\text{S}_2\text{O}_2\) is a blue-green solid, consisting of a mass of microscopic crystals. Insoluble pure \$\text{S}_0\text{, if a little \$H_SO_1\) is present the \$S_0\text{, dissolves to a deep-blue liquid. Melts with decomposition; decomposes slowly in dry air, quickly on heating, to \$\text{S}_0\text{ and \$S}; deliquesces in moist air to a brown liquid from which \$S\text{ soon separates; reacts violently with water, giving \$H_SO_4\text{A}, \$H_S^2_0\text{Aq}, \$P_0\text{Aq}, \$P

S.O. may be regarded as the anhydride of H.S.O.; although the acid has not been ob-

tained from the oxide, nor the oxide from the acid.

For the compounds SSeO, and STeO, v. Sclenion thio oxide (p. 441) and Tellurium thio oxide (under Tellurium oxides).

SULPHUR DIOXIDE SO. (Sulphurous oxide. Sulphurous anhydride. Thionyl oxide.) Mol. w. 63-9. Melts at c. -76° (Faraday, T. 1845. 155); c. -80° (Mitchell, A. 37, 356). Boils at c. -10³ (Bunsen, P. 46, 97; Andréeff, J. 1859; Pictet, C. C. 1877. 81). S.G. (liquid) 1-4911 at -20-5°, 1-4384 at -2-20-8°, 1-4252 at +2-28°, 1-363 at 20°, 1-3258 at 38-65° (Andréeff, A. Ch. [3] 56, 317); 1-4338 at 0°, 1-2872 at 52°, 1-1845 at 82-4°, 1-1041 at 102-4°, 956 at 130-3°, 7317 at 151-75°, 52 at 156° (Cailletet a. Mathias, C. R. 104, 1563). S.G. (gas at 0° and 760 mm.) 2-2639 (Leduc, C. R. 117, 219). V.D. 32-23 (Gay-Lussac, Berzelius, Buff; Biltz, B. 21, 2769). S.H. (equal wt. water = 1) -1544; (equal volume air = 1) -3414 (Regnault, J. 1863, 84). Ratio of S.H. constant pressure to S.H. constant volume = 1-2562 (Müller, W. 18, 94). C.E. -00423 for 1° between 0° and 10°, 004005 10° to 20°, 003686 at 50°, 003757 at 160°, 003765 at 150°, 003795 at 200°, 003686 at 250° (Amagat, C. R. 73, 183; cf. C.R. 68, 1170). Leduc (C. R. 117, 219) gives C.E. between 0° and 20° as 00396. For C.E. of liquid SO₂ v. Drion (A. Ch. [3] 56, 5) and Andréeff (A. 110, 1). The

ratio PV >1; Amagat (l.c.) gives these values,

1.0185 at 15°, 1.0110 at 50°, 1.0054 at 100°, 1.0032 at 150°, 1.0021 at 200°, 1.0016 at 250°. II.F. [S,O²] = 71,070 from solid rhombic S; 71,720 from solid monoclinic S (Th. 2, 247). Heat of liquefaction of gaseous SO₂ = 5644 (Favre, A. Ch. [5] 1, 209). Critical temperature = 156° (Caillett a. Mathias, C. R. 104, 1563); 155·4° (Sajotscheffski, P. B. 1879. 741); 157°—161° (Ladenburg, B. 11, 821). Heat of vaporisation of liquid SO₂, at 0°, = 91·2, at 60° = 60 (C. a. M., l.c.; cf. Chappuis, C. R. 104, 897). Regnault (C. R. 50, 1063) gives vapour pressures as follows:

Temp.		Temp.	Vap. pressure	
- 25° - 20 - 10 0 + 10	373·79 mm. Hg 479·46 " 762·49 " 1165·06 " 1719·55 "	30° 40 50 60	3131·80 mm. Hg 4670·23 ", 6220·01 ", 8123·80 ",	•
20	2462.05 ,,	-	,, ,, ,,	

Vapour-pressure at critical temp. = 78-9 atmos. (Sajotscheffski, P.B. 1879. 741). \bullet S. in water between 0° and 20° (gaseous SO₂) = 79-789 - 2-60774 + 029349 t^* ; 1 vol. of the saturated SO₂Aq contains 68-861 - 1-87025t + 01225 t^* vols. SO₂; S. (water) between 21° and 40° = 75-182 - 2-1716t + 01903 t^* ; 1 vol. of the saturated SO_AQ contains 60-952 - 1-3889t + 0072 t^* vols. SO₃ (Bunsen a. Schönfeldt, A. 95, 2). S. in alcohol, at 760 mm. = 328-62 - 16-95t + 3119 t^* ; S.G. of solution = 1-1193t - 014091t + 00025 t^* (Carius, A. 94, 148). Sims (C.J. 14, 1) gives the table on the next page, which presents both the weight of SO₂ in grams and the volume of gaseous SO₂ in c.c. dissolved by unit weight of water at the normal pressure and different temperatures:

	Grams SO.	. o.c. SO,		
Temp.	absorbed by 1 g., vater			
8°	·168	58· 7		
12	.142	49.9		
16	·121	42.2		
20	·104	36.4		
24	.092	32.3		
28	.083	28.9		
82	.073	25.7		
86	.065	22.8		
40	.058	20.4		
44	.053	18.4		
48	.047	16.4		
60	•045	15.6		

The quantity of SO₂ dissolved by a given weight of water varies with pressure, and only at c. 40° and upwards is the quantity proportional to the partial pressure of the gas (v. Sims, C. J. 14, 1). For S.G. and composition from 5 to 10 p.c. of SO₂Aq v. Anthon (C. C. 1860, 744); also Giles a. Schearer (S. C. I. 4, 303). [SO²/3Aq] = 7,700 (gaseous SO₂) (Th. 2, 249); 1500 (liquid SO₂) (Berthelot, C. R. 96, 142, 208; Chappuis, A. Ch. [2] 19, 21). H₂SO₂Aq absorbs the following quantities of gaseous SO₂ (Kolb, D. P. J. 209, 270; cf. Dunn, C. N. 43, 121; 45, 270):—

B.G. H.SO.Aq	Kilos, SO ₂ per kilo, acid	litres SO, per litre acid
1.841	.009	5-8
1.839	.014	8.9
1.540	.021	11.2
1.407	.032	15.9
1.227	.068	29.7

SO₂ is absorbed by charcoal; 1 c.c. charcoal = 1·57 g. was found by Favre (A. Ch. [5] 1, 209) to absorb 165 c.c. SO₂. Camphor absorbs c. 308 times its vol., glacial acetic acid c. 318 times, SO₂Cl₂ c. 187 times, its volume of SO. (Schulze, J. pr. [2] 24, 168; Bineau, A. Ch. [3] 34, 326). $\mu_{\rm Na}=1\cdot35$ at 15° (Bleckrode, Pr. 37, 359). For surface tension of liquid SO₂ v. Clark (C. N. 38, 294; 40, 8). For absorption-spectrum v. Liveing a. Dewar (C. N. 47, 121).

Occurrence.—In volcanic gases, and in river and spring water near volcanoes (v. Ricciardi, G. 18, 38).

Formation.—1. By burning S in O. Baker (Pr. 45, 1; C. J. 47, 349) found that the combustion of S in O is retarded the drier the O is; using very carefully dried O there was no flame. According to Hempel (B. 23, 1456) c. 2 p.c. of the gas formed when S is burnt in O at the ordinary pressure is SO₃, 98 p.c. being SO; at a pressure of 40°-50° atmos. c. half the S is burnt to SO, and half to SO; at higher pressures c. 70 atmos. the proportion of SO, increases.—2. By heating S with oxide of Pb, Mn, Hg, Zn, Xc.—3. By heating various sulphates with S, also SO, with S, or cone. H, SO, with C, Cu, Hg, or S; by heating Na, SO, with charcoal and BiO₂.—4. By the decomposition, by acids, of alkali thiosulphate or polythionate solutions.—5. By burning H,S, CS, and various organic compounds containing S.—6. By decomposing cone. H, SO, by heat.—7. By the action of electric sparks on a mixture of sulphur with CO, NO, or N,O (Chevrier, C. R. 69, 136).

Preparation. -1. Pure H.SO, mixed with half to two-fifths its volume of water, is heated with pure Cu; the SO, that comes off is passed through water in a large flask, and then through a couple of bottles filled with pumice, broken into small pieces and moistened; the pumice should be twice moistened with pure H.SO, and heated to redness before being used, to remove chlorides and fluorides (Stas, Chem. Proport. chlorides and fluorides (Stas, Chem. Proport. 115). The SO₂ may be dried by passing it through pure conc. H₂SO₄, and then over CaCl₂.—2. A mixture of 3 parts pure CuO and 1 part S in powder is heated in a tube of hard glass; the anterior part of the tube contains CuO only, to oxidise S that may subline (Marchand, P. 42, 114).—3. Neumann (R. 20, 1584) obtains a require stream of any (B. 20, 1584) obtains a regular stream of ap-(B. 20, 1964) obtains a regima sardam of approximately pure SO₂ by placing a mixture of three parts CaSO₃ and 1 part CaSO₄, made into small cubes, in a Kipp's apparatus, and decomposing by ordinary oil of vitriol. The acid should be allowed to come into contact with sufficient cubes, and no more, to give the stream of gas that is required. Using c. 500 g. of the cubes, N. obtained a constant stream of SO₂ for 30 hours. The cubes are made by mixing the CaSO, and CaSO, moistening with water so that a semi-solid mass is obtained that can be worked with the fingers with some difficulty, pressing this in an iron mortar, hammering it into an iron frame c. 10-12 mm. in height, covering with oilcloth and pressing strongly, cutting into cubes while still in the frame, removing and drying at c. 20° (v. Winkler, B. 20,

Properties.—A colourless gas, at ordinary temperatures and pressures, with the strong penetrating, choking odour of burning S; causes coughing and blood-spitting if inhaled in any quantity. Incombustible in air, and extinguishes flame; when mixed with O and passed over heated spongy Pt it is oxidised to SO₃. Dry SO₃ is said not to redden litmus paper (Wilson, C. J. 1, 332). Bleaches many vegetable colours; the colours are generally restored by alkalis. Bad conductor of electricity (v. Bleekrode, P. M. [5] 5, 375, 439). Is not decomposed by passing through a red-hot, tube. Condensed at c.—10° under the ordinary pressure—by passing the dry gas into a tube surrounded by a mixture of snow and salt; may also be condensed at the ordinary temperature by evolving the gas (by warming charcoal saturated with SO₂, or a mixture of 1 part S and 5 parts SO₃ in one limb of a closed tube, the other limb being placed in cold water. Convenient apparatus for fiquefying SO₃ is described by Wohler (4. 137, 371) and Hofmann (B. 2, 262).

(B. 2, 262).

Liquid SO, is a colourlyss, mobile liquid. Exposed to air it evaporates very rapidly, with disappearance of much heat; an air thermometer placed in liquid SO, at 10°, in an open vessel, falls to -57°. Liquid SO, dissolves P, S, I, Br, and many gums. It is miscible in all proportions with liquid SO,; partially miscible with CS₂, Et,O, CHCl₃, and C,Ia, on warming; but immiscible with conc. H₂SO, (Sestini, Bl. [2] 10, 226). Liquid SO, is a n-on-conductor of electricity (Magnus, P. 104, 532).

By evaporating liquid SO, r'apidly in an airpump, part of it solidifies to a white, woolly

mass: the liquid may also be solidified by placing it in a mixture of solid CO, and ether.

Reactions and Combinations.-1. SO, is not decomposed by passing through a red-hot tube. But by heating to c. 1200° it is changed to SO. and S (3SO. = 2SO. + S); the action stops when the SO₂ attains a certain vapour pressure, but if the SO₂ is removed (by conc. H₂SO₄) the whole of the SO₂ is decomposed (Deville, C. R. 60, 317). Induction sparks effect the decomposition of SO, to SO, and S (v. Buff a. Hofmann, A. 113, 129); light acts similarly (Morren, C. R. 69, 397).—2. H₂O and S are produced by passing SO, mixed with hydrogen through a red hot tube.—3. Ohlorine combines with SO₂, in sunlight, to form SO₂Cl₂ (v. SULPHURYL CHLORIDE). SO₂Cl₃ is also formed by passing SO₂ and Cl into glacial acetic acid, even in the dark; also by passing SO₂ over charcoal saturated with Cl (Melsens, C. R. 76, 92),—4. Ozone produces SOs; the same compound is formed by passing SO₂ mixed with oxygen over heated spongy Pt, or by burning SO₂ in O under a pressure of several atmos. (v. supra; Formation, No. 1). According to Berthelot (A. Ch. [5] 12, 463), S.O. is formed by the action of the silent discharge on SO₂ mixed with oxygen. The compound S2O, N2 is said to be formed by passing electric sparks through a mixture of SO₂ and air. This compound is probably S₂O₅(NO₂)₂ (v. NITROSULPHONIC ANHYDRIDE, p. 601). -5. Passed over red-hot carbon the products are CO, CO, and S; COS and CS2 are also sometimes formed, probably by secondary reactions (Scheurer-Kestner, C. R. 114, 296; cf. Berthelot, Bl. [2] 40, 362; Eilsart, J. 1885. 457).—6. Potassium burns when heated in SO., giving K₂SO₄, K₂S₂O₃, and polysulphides.—7. Many other *metals*, especially when in fine powder, burn in SO2; Sb and Sn form oxides and sulphides; Fe, sulphide and sulphate; Pd and Pt, sulphides and SO3; Au, sulphate; Fa and Ft, sulphates and SO₃, I.a., S and SO₃; Mg, sulphate, sulphite, and sulphide; Al, Co, Ni, and Zn also burn; Bi and Hg do not react (Schiff, A. 67, 94; 117, 92; Uhl, B. 23, 2151).—8. Water dissolves SO₂, 9. Several metallic peroxides combine readily with SO, forming sulphates; e.g. PbO₂+SO₂ = PbSO4; in this reaction much heat is produced .- 10. Nitrogen dioxide is said to react ausea.—10. Nurogen aboxase is said to react with liquid SO, to form nitrosulphonic anhydride S₂O₅(NO₂)₂ (v. p. 601). With nitric oxide or dioxide, in presence of water, nitrosulphonic acid NO₂(SO₂OH) (q. v., p. 601) is formed. Nitric oxide in presence of alkali produces salts of SO₂OH(NO)₂H (v. NITROSOSUL-PHATES, p. 581).—11. Selenion dioxide does not react with SO (Schulze J. gr. [2] 32 not react with SO₂ (Schulze, J. pr. [2] 32, 890). -12. Dry hydrogen sulphide does not react; moist H₂S, at the ordinary temperature, produces H₂S, O₄, S, and H₂O (Cluzel a. Schmid, Chem. Zeitung, 11, 50); there is said to be no reaction in presence of water above 400° (Mulder, J. 1858. 84).—13. Phosphoretted hydrogen reacts at the ordinary temperature to form H₂O and P₂S₄ (C. a. S., l.c.).—14. Ammonia combines with SO₂ probably producing SO₂,NH₂ (= SO.OH.NH₂) and SO₂2NH₂ (= SO.ONH₂,NH₂) (v. Thionamio acid).—15. Hydrochloric or hydriodic acid produces H₂O, S, and Cl or I.—16. Many oxysails, e.g. nitrates and chlorates, react with

SO₂, when heated, to form sulphates and Noxides; at higher temperatures SO₃ is sometimes produced (v. Hodgkinson a. Young, C. N. 66, 199).—17. Alkali nitrites yield salts of nitrilosulphonic acid N(SO,OH), (q. v., p. 601), and salts of oxy-imidosulphonic acid N(OH)(SO,OH), (q. v., p. 602).—18. Combines with aluminium chloride at 50°-60°, forming AlCl. SO, which gives off SO, at a higher temperature (Adrianoffski, B. 12, 688). - 19. Phosphorus pentachloride produces POCl, and SOCl, (Kremers, A. 70, 297; Schiff, A. 102, 111).

SULPHUR THOMBS SO. (Sulphuric oxide. Sulphuric anhydride.) Mol. w. 79:86. Melts at 14:8° (Weber, B. 19, 3189; Rebs, A. 246, 356). Some other observers have given m.p. as high as 20.5° (v. Buff, A. Suppl. 4, 129; Bussy, A. Ch. [2] 26, 411; Fischer, P. 16, 119; Marignac, A. 88, 230). Boils at 46.2° (Weber, l.c.; v. also Buff, l.c.; Fischer, l.c.; Schultz-Sellack, P. 139, 480). S.G. 1.94 at 16° (Weber, Lc.); 197 at 203 (Bussy, Lc.); 19086 at 253 (Buff, Lc.). V.D. 3978 (Schultz-Schack, P. 139, 480; Perman, Pr. 48, 45). H.F. [S,0³]=103,240 (liquid SO, from solid S; Th. 2, 254); [SO³, O]=32,160 (liquid SO, from gaseous SO²; Th., l.c.); [SO³, Aq]=39,170 (liquid SO₃; Th., l.c.). For heat of vaporisation v. Berthelot (C. R. 90, 1510). Schultz Sellack gives vapour-pressure at 20° as 15°2 mm. Hg (P. 139, 480).

Formation.—1. By the interaction of ozone and SO.. Also by the action of an induction

current on a mixture of SO₂ and O₂ (Buff a. Hofmann, A. 113, 129; Deville, Bl. [2] 3, 366); Berthelot (C. R. 86, 20) says that the product is S.O .. -- 2. By burning S in O under a pressure of several atmos. (v. Sulphur Dioxide, Formation Nc. 1). Also by heating pyrites (Scheurer-Kestner, G. R. 99, 917; Lunge, B. 10, 1824). 3. By passing a mixture of SO, and O over heated Pt (Phillips a. Magnus, P. 24, 610), spongy Pt (Hodgkinson a. Lowndes, C. N. 57, 102) 193), or certain oxides, e.g. Fe₂O₃, GuO, Gr₂O₃ (Mahla a. Wöhler, A. 81, 255).—4. By heating certain sulphates or bisulphates, c.g. Fe2(SO4), Bi₂(SO₄)₃, Ag SO₄, or NaHSO₄.—5. By distilling Nordhausen sulphuric acid (v. Osann, D. P. J 151, 158); also by heating conc. H,SO, with P,O, (Barreswil, C. R. 25, 30; Evans, Ph. 8, 127).

Preparation.—1. Fuming sulphuric acid is

heated at as low a temperature as possible; the impure SO, is collected in a dry retort and redistilled once or twice, the most volatile portion being collected each time. The partially purified SO, is then distilled into a small tube, c. 8-10 mm. wide and about the length of a finger, containing some dry P.O.; this tube is narrowed at one end and fused on to a thick-walled tube c. 1-1.5 mm. wide, which is bent round and fused to a receiving tube c. 12-15 mm. wide and 300 mm. long; the tube containing the SO₃ and P₂O₅ is heated in a water-bath to 90°-100° for 6 or 8 hours, the receiving true projecting upwards, so that the distillate flows back again into the distilling-tube. The position of the apparatus is then changed, so that the receiving tube is lower than the distilling tube, and the SO is distilled from the P₂O₂ on a water-bath. When sufficient SO, has been collected, the narrow connecting tube is fused off, and the SO, is kept in the sealed receiving tube (Weber, B. 19, 3189).— 2. A mixture of SO₂ and O, in the ratio SO₂:O, is passed over platinised asbestos beated nearly to redness; the SO₂ is condensed in a small dry tube, in which it is sealed up. The mixture of SO₂ and O is obtained by strongly heating cone. H₂SO₂ and removing H₂O (H₂SO₄ + H₂O + SO₂ + O) by cooling and passing through coke moistened with 60 p.c. H₂SO₄Aq (Winkler, D. P. J. 218, 128). The asbestos is platinised by soaking in PtCl₁Aq made alkaline by soda, and mixed with sufficient HCO₂Na to reduce the Pt, drying at 100°, carefully washing out the salts with water, and drying (Thomsen, B. 3, 496). The SO₃ thus obtained is not quite pure. It may be purified by distillation with P₂O₃ (v. supra).

Properties.—A colourless, mobile liquid, so-

Properties.—A colourless, mobile liquid, solidifying at c. 15° to long, prismatic, transparent crystals, which melt at 14.8°. According to some observers (v. Marignac, Ar. Ph. 22, 225; 58, 228; Schultz-Sellack, P. 139, 480) the crystals of SO, slowly change to a mass of tough, opaque, lustrous needles, which melt above 50°, and constitute a distinct modification of SO, is but the experiments of Weber (P. 139, 480; B. 19, 3187; cf. Rebs, A. 246, 356) have shown that pure SO, exists only in one form, and that the substance with higher mp. is formed by the action of traces of H₂SO₄ in the SO₃; a small trace of moisture suffices to cause the gradual change. SO₄ is very acrid and poisonous; it chars paper, wood, and organic matter generally. SO₃ is extremely hygroscopic; it dissolves in water with a hissing sound and production of much heat ((SO³,Aq) = 39, 170), forming H₂SO₄Aq. Non-conductor of electricity (Magnus, P. 104, 558); not decomposed by electric sparks, but by passing through a red-hot tube gives SO₂ and O. SO₄ does not redden dry litmus. It is a strongly said-forming exide. Surehum care surface and surface surface and constitute surface and constitute and constitute surface and constitute surfac

acid-forming oxide (v. Sulphuric acid).

Reactions and Combinations.—1. Heated to redness (by passing through red-hot tube) gives SO₂+O.—2. Not decomposed by electric sparks (Magnus, P. 104, 553); electrolysis of SO₃ in H.SO₃ causes separation of S and O, and the solution becomes blue (Geuther, A. 109, 129).—3.

**Water reacts violently with SO₃ forming H.SO₄Aq (v. Sulphuric acid).—4. Hydrogen sulphide produces H.SO₃ and S.—5. A mixture of SO₃ and oxygen, in the ratio 2SO₃:O₃ forms S₂O₃ when submitted to the silent electric discharge (Berthelot, A. Ch. [5] 14, 345).—6. Sulphur dissolves in SO₃ forming S₂O₃; selenion and tellurium react similarly (v. Sulphur HIDO-OXIDS, BELENION THIO-OXIDS, And TELLURIUM THIO-OXIDS, PRICENION THIO-OXIDS, Torming P.O₃ and S.—8. Iodine dissolves in SO₃, apparently forming several compounds (v. Wach, S. 50, 37; Schultz-Sellack, B. 4, 109), Weber (J. pr. [2] 25, 224) describes the compounds I(SO₃), I(SO₃), and L(SO₃).—9. Iron and sinc react at red heat to give sulphides and coides; mercury produces sulphate and SO₄ (d'Heureuse, P. 75, 255).—10. Several metallic sulphides—e.g. of Sb, Pb, K.—form sulphates and SO₂ when heated with SO₃ (Weber, P. 130, 329).—11. Dry sulphur dioxide is absorbed by SO₂ at O', forming a thin, tuming liquid, approximately SO₂-2SO₂ (H. Rose, P. 89, 178), According to Schultz-Sellack, liquid SO₂ and SO₃ are miscible in all proportions (P. 189, 480).

(v. Selenion divide, Combinations, No. 4, 3, 441).—18. Nitric oxide, in absence of moisture, and O, forms S₂O₂N₂, which is generally called nitrosulphonic anhydride (q. v., p. 601) and written S₂O₂(NO₂)₂. Nitrogen dioxide (made by heating Pb(NO₂)₂) seems to form SO₂, NO₂, and on heating this and passing in more NO₂, O is given off and the compound S₂O₂N₂ remains (v. Weber P. 128, 337. Briging A. 98, 877). Weber, P. 123, 337; Brüning, A. 98, 377). The formula of the first of these compounds is generally doubled, and the compound regarded as $S_0 t_* O_* (NO_3)_2 = oxynitrosulphonic anhydride (q. v., p. 601); the second is described in some books as <math>S_0 O_1(NO)_2$ and is called nitrosyl pyrosulphate, but from the descriptions of Weber and Bruining it is evidently the same as the compound $S_1 O_2 N_2$ formed from NO and SO_3 , i.e. it is nitrosulphonic anhydride.—14. SO_3 combines with iodine pentoxide to form $SO_3 I_* O_3$ and $SO_3 \cdot S_1 O_3$ (Weber, B. 20, 86; Kämmerer, J. pr. 83, 72). With phosphorus pentoxide $SSO_3 \cdot P_2 O_3$, decomposing at $SO_3 \cdot SO_3 \cdot O_3 \cdot O_3$ and $SO_3 \cdot SO_3 \cdot O_3 \cdot O_3$ generally doubled, and the compound regarded oxide forms various unstable compounds (Adie. C. J. 55, 167; cf. Weber, B. 19, 3185; Schultz-Sellack, B. 4, 109; Reich, J. pr. 90, 176; Schafhaütl, B. J. 22, 113; and Pearce, Z. K. 20, 632). According to Baker (C. J. Proc. 1893. 130), dry SO, does not react with dry oxides of 130), dry SO₃ does not react with dry cxides of barrium, calcirum, or comper.—15. The compound SO₂.N.O₃.5H.SO₄ is said to be formed by passing SO₃ into pure, well-cooled, nitric acid (Weber, P. 123, 233; 142, 602).—16. Boric acid forms BH.O₂.8SO₃ [=B(HSO₄)₃] (D'Arcy, C. J. 55, 155; cf. Merz, J. pr. 99, 81; Schultz-Sellack, B. 4, 15).—17. Hydrobromic and hydriodic acids reported Broad Land town HSO₂ acid SO₂ separate Br, and I, and form H2SO, and SO2 --18. Hydrochloric and hydrofluoric acids form Cl(SO₂OH) and F(SO₂OH) (v. CHLOROSULPHONIO ACID, p. 599; and FLUOSULPHONIC ACID, p. 600). 19. Conc. sulphuric acid forms H,S_QO, (v. PYNO-SULPHURIC ACID, p. 625).—20. Ammonia produces NH₄(SO₂.OH) and salts of this acid (v. SULPIRMIC ACID AND SALTS, p. 567); and also salts of NH(SO₂.OH), (v. IMIDOSULPHONIC ACID AND SALTS, p. 600).—21. Phosphoretted hydrogen produces SO₂ and red P (H. Rose, P. 24, 140; Aimé, J. pr. 6, 79).—22. Phosphorus trichloride reacts violently, forming POGl, and SO₂ (Armstrong, B. 3, 732; Michaelis, J. Z. 6, 239). Phosphorus pentachloride produces pyrosulphuryl chloride S,O,Cl. (q. v. under Sulphur oxyglicheries, p. 617).—23. Boron chloride reacts at c. 120° to form S,O₃Cl₂ (Prudhomme, Bl. [2] 14, 385).—24. Nitrosyl chloride (produced by heating aqua regia) produces SO₂NOCl = NO₃(SO₂Cl) (v. NITROSULPHONIC GHLORIDE, p. 601).—25. Pyrosulphuryl bromide S,O₃Rr; (q. v., p. 617) is perhaps formed by the reaction 19. Conc. sulphuric acid forms H2S2O, (v. PYRO-(q, v., p. 617) is perhaps formed by the reaction of bromoform with SO₃.—26. Selenion tetrachloride produces SSeO₂Cl₄ (v. Selenion Thio-OXYCHLORIDE, p. 441).

SULPHURIO PEROXIDE S₂O₂. (Sulphur heptoxide. Persulphuric anhydride.) Mol. w. not known with certainty but probably 176-68 (S₂O₂). This oxide was prepared by Berthelot in 1877: (A. Ch. [5] 14, 345) by passing the 'silent' electric disoharge, for several hours, through a mixture of SO₂ and O in the ratio 2SO₂:0, or of SO₂ and O in the ratio 2SO₂:8O. (For apparatus used *e. B., A. Ch. [6] 12, 468.) Oily drops.

formed on the sides of the tube, and on redusing the temperature nearly to 0° they solidified to long, white, crystalline, needles. S₂O, resembles solid SO, in appearance; it remains schanged in a scaled tube for some days at 0°; when heated it gives SO, and O; dissolves in conc. H.SO, forming a fairly stable solution; fumes in the air; in water it rapidly decomposes forming H,SO,Aq and giving off a brisk stream of O; with BaOAq forms BaSO, and O; and also some Ba persulphate, according to Berthelot (La; no analyses given). By electrolysing H₂SO₄Aq, containing water and acid in the ratio 10H₂O:H₂SO₄, B. (C. R. 90, 269) obtained a quantity of persulphuric acid (H2S2O8; v. under Sul-PHURIC ACID, p. 625) equal to from 88 to 123 g. S₂O₂ per litre; using an acid of the concentra-tion H₂SO₄:2H₂O to II₂SO₄:3H₂O₄ B. (*l.c.*) says that a compound S2O, 2H2O2 is formed, which is decomposed by excess of conc. H₂SO₄ chiefly to H₂S₂O₈, and by dilution with water to H₂S₂O₈Aq and H₂O₂Aq which after a time decompose to H2SO, Aq, H2O, and O.

S₂O₇ is the anhydride of persulphuric acid H₂S₂O₈ (q. v., p. 625). Mendelceff (B. 15, 242) regards S₂O₇ as analogous in constitution to

 H_2O_2 , and writes the formula $\begin{vmatrix} OSO_2 \\ OSO_2 \end{vmatrix}$

looks on the corresponding acid as derived from H.O. by replacing 2H by 2SO.OH, thus: O.(SO.OH)

y (20 OH)

According to Traube (B. 22, 1518; 24, 1764; 25, 95), the liquid obtained by electrolysing 40 p.c. H₂SO₄Aq contains an oxide to which he gives the formula SO₄ and calls sulphuryl hyperoxide (or holoxide), SO_{...}O₂. Traube did not isolate this compound; his argument for its existence is based on the results of indirect analyses. In the light of the criticisms of Carnegie (C. N. 64, 158) it may be concluded that the existence of SO₄ is extremely improbable. In a later communication (B. 26, 1481) Traube thinks it is probable that SO₄ does not exist.

Sulphur, oxyacids of. For compositions of these acids, and references to articles where they are described, v. Sulphur, oxyacids of (p. 610)

Sulphur, oxyacids of, nitrogen derivatives of. For a general statement regarding these compounds, and roferences to the articles where they are described, v. Sulphub oxyacids, NITHOGEN DERIVATIVES OF (p. 619).
Sulphur, oxybromides of. There is very

Sulphur, oxybromides of. There is very little definite knowledge regarding the compounds of S, O, and Br. According to Michaelis (J. Z. 6, 239, 296) PBr, does not react with SO, and a mixture of PCl, and Br (in the ratio PCl, Br.) produces POCl, and S bromides. Rose (P. 44, 327) and Clausnizer (B. 11, 2012) could not obtain an oxybromide by the reaction of SO, and S bromide, nor by the action of SO, and HBr.

In his memoir on S₂O₂Cl, prepared by the reaction of SO₂ with CHCl₂, Armstrong (B. 2, 712) at that CHBr₂ reacts with SO₂ similarly to CHCl₂, but he does not describe the product. If the reaction of CHBr₂ with SO₂ is strictly similar

to that of CHCl, the product would be pyrosulphuryl bromide S.O.Br.. Odling (C. J. 7, 2) supposed that sulphuryl

Odling *C. J. 7, 2) supposed that sulphuryl oxy-bromide SO,Br, was formed by the action of sunlight on SO, and Br, but Sestini (Bl. [2] 10, 226) and Melsens (C. R. 76, 92) failed to obtain an oxybromide by this method.

THONYL BROWIDE SOBL. This compound was obtained, but not quite free from S bromides, by Hartog a. Sims (C. J. Proc. No. 118, 1898.

10) by the interaction of SOCL and NaBr; it is described as a very hygroscopic, orimson liquid, S.G. 268 at 18°, decomposing at 150° to Br, S bromides, &c.

Sulphur, oxychlorides of. Five compounds have been isolated, SOCl., SO₂Cl., S₂O₂Cl., S₂O₂Cl., and S₂O₄Cl.

THONUL CHLORIDE SOCI, (Sulphurous oxy chloride). Mol. w. 118-62. Boils at 78-8°; S.G. & 1-67673, S.G. at b.p. 1-52143 (Thorpe, C. J. 37, 354; for other data v. Carius, A. 106, 303; 111, 93; Wurtz, C. R. 62, 460). V.D. at c. 150° = 56; at c. 440° = 39 (Heumann a. Köchlin, B. 16, 1625). H.F. [S.O.Cl²] = 40,800; heat of vaporisation = 6,480 (Ogfer, C. R. 94, 82). S.V. 78-01 (Thorpe, L.).

Formation.—1. By the reaction of PCl, with SO₂ (Kremers, A. 70, 297; Schiff, A. 102, 111), SO₂Cl., C,H₂,SO₂Cl, and several other organic compounds containing S (v. Kekulé a, Barbaglia, B. 5, 875; Carius, J. pr. [2] 2, 262), sulphites, or thiosulphates; also by the reaction of POCl₃ with sulphates.—2. By the action of Cl₂O on CS₂, or on S in S₂Cl₂ at -12° (Wurtz, C. R. 62, 460).—3. By the interaction of SO₂ and SCl₁ (Michaelis a. Schilferdecker, B. 5, 924; 6, 993).—4. Along with SO₂Cl₂ by the gradual decomposition of S₂O₄Cl₄ (r. v. p. 619).

Preparation. -1. About 100 g. dry PCl, are placed in a retort connected with a reversed condenser, and a stream of dry SO, is led in till the PCI, has liquefied; another 100 g. PCI, is added and the stream of SO, is continued; when sufficient PCl, has thus been decomposed (PCl₅ + SO₂ = SOCl₂ + POCl₃) the liquid is heated for some time (the reversed condenser being still attached) to get rid of SO., and then fracson attached to get rid 180, and then have tionated repeatedly (SOCI, boils at 78.8° and POCI, at 107.2°) (Carius, A. 106, 303; 111, 98; Wurtz, A. 139, 375; Michaelis, A. 170, I Thorpe, C. J. 37, 354.—2. S.C.I is placed in a small flask, cooled to c. -20°, a stream of dry Cl is led in till the liquid is saturated, and then SO, is distilled into the flask from a solution in conc. H2SO,; the weights of S.Cl. and SO. used should be in the ratio S,Cl,:480, (=1:2:37) convenient quantities to use are 22 g. S.Cl., and 50 g. SO. (SCl. + 2SO. = SOCl. + S.O. Cl.). The liquid is fractionated finally from a small quantity of SO. (Michaelis a. Schifferdecker, B. S. O. C. G. O. C. 5, 924; 6, 993).

Properties.—A colourless, very refractive liquid, fuming in the air, with a very penetrating odour; vapour attacks the eyes and respiratory organs. V.D. 56 at c. 150°, but 39° at c. 440°; the smaller value corresponds with the decomposition 4SOCl₂ = S₂Cl₂ + 2SO₂ + 8Cl₂; these products are obtained by passing vapour of SOCl₂ through a red-hot tube (Heumann a Köchlin, B. 16, 1625).

Reactions and Combinations.—1. Moist air produces HOI and SO₂.—2. Water also forms HOIA4 and SO₂, warm water forming in addition H₂SO₂Aq and S (Garius, l.c.).—3. Hydrogen sulphide produces SO₂, HCl, and S (Prinz, A. 225, 371).—4. Phosphorus pentasulphide reacts to form SO₂, PSCl₃, and S, and some S₂Cl₂ (Prinz, l.c.).—5. With antimony trisulphide the products are SbCl₃, SO₂, and S.—6. Sulphur, heated to 180° with SOCl₂, forms S₂Cl₂ and SO₂; selenion forms S₂Cl₂ and SSeCl₂ (Prinz, l.c.).—7. Powdered antimony reacts without heating, forming SbCl. Reactions and Combinations .- 1. Moist air antimony reacts without heating, forming SbCl, Sb.S., and SO.—8. POCl., PSCl., and PCl., are formed by heating SOCl. with phosphorus trichloride (Michaelis, J. Z. 6, 239).—9. Heating chloride (Michaelis, J. Z. 6, 239).—9. Heating with sulphur dichloride produces S₂OCl, (q. v., p. 619) (Ögier, Bl. [2] 37, 293).—10. Ammonia does not produce thionylamide SO(NH₂)₂, but forms NS, NH₂Cl, (NH₂)₂O₃, and NH₄ polythionates (M., l.c.).—11. Reacts rapidly with silver mitrate, forming NO₂(SO₂Cl) (Thorpe, C. J. 41, 297).—12. SOCl₂ absorbs sulphur dioxide and chlorine freely (M., l.c.).—13. For reactions with various organic convocunds n reactions with various organic compounds v. Michaelis (l.c.); Heumann a. Köchlin (B. 16, 1625); Böttif ger (B. 11, 1407).

SULPHURYL CHLORDE SO₂Cl₂ (Sulphuric oxychloride). Mol. w. 134·58. Boils at 69·95° (Thorpe, C. J. 87, 859; for other determinations v. Regnault, J. pr. 19, 243; Clausnizer, B. 11, 2010; Ogier, C. R. 94, 82). S.G. 20 1.70814; at

b.p. 1-56025 (Thorpe, l.c.). V.D. 65 at 184°, 34 at 440° (Heumann a. Köchlin, B. 16, 602; cf. Regnault, J. pr. 18, 97; Behrend, J. pr. [2] 15, 23). S.V. 86'29 (Thorpe, l.c., p. 372). H.F. [S.O',Cl'] = 89,780; [SO',Cl'] = 18,700 (Th. 2, 810; cf. Ogier, C. R. 94, 82). S.H. (15°-63°) 233 (Ogier, l.c.). Heat of vaporisation 7,060 (O. l.c.).

(O., l.c.).

Formation.-1. By the direct combination of SO, and Cl in sunlight, or by reacting on a mixture of C₂H₄ and SO₂ by Cl in sunlight (Regnault, *J. pr.* 18, 93; 19, 243). Schulze (*J. pr.* [2] 23, 351; 24, 168) recommends to allow SO₂ and Cl to react in presence of camphor. Melsens and Cl to react in presence of camphor. Melsens (C. R. 76, 92) passes SO₂ and Cl into glacial acetic acid.—2. By passing SO₃ over charcoal saturated with Cl (M., l.c.).—3. By the interaction of PCl, with H₂SO₄ or SO₅ (Williamson, P. M. (4) 7, 865; Schiff, d. 102, 111); according to Michaelis (J. Z. 6, 233, 292), SO₃ and PCl₃ form 8₂O₄Ol₂—4. By heating SO₅ and BCl₃, in the ratio 2SO₂:BCl₃, to 120° in a closed tube (Gustavson, B. 6, 9).—5. By heating Cl(SO₂·OH) to a 200° for some time (Behrend, B. 8, 1004; cf. Otto a. Beckurts, B. 11, 2058). cf. Otto a. Beckurts, B. 11, 2058).
Preparation.—1. Cl and SO, are passed into

camphor, and the colourless liquid is fractionated (Schulze, l.c.).—2. Cl(SO₂.OH) (v. Chloro-sulphonic acid, p. 509) is heated to c. 200°, in a closed tube, for some hours, when it decomposes thus, $2[Cl(SO_*OH)] = SO_*Cl_2 + H_2SO_4$; the liquid

thus, $2[\mathrm{Cl}(\mathrm{SO_s,OH})] = \mathrm{SO_sCl_s} + \mathrm{H_sSO_s}$; the liquid is distilled, the portion coming over at 67° – 71° being collected separately and then repeatedly fractionated (Behrend, *l.c.*; cf. Thorpe, *l.c.*).

Properties and Reactions.—A colourless liquid, fuming slightly in air. 1. Decomposed by heating to dull redness into $\mathrm{SO_s}$ and Cl ; decomposition is complete at 440° (Heumann a. Kochlin, B. 16, 602); but does not begin at 250°

(Beckurts a. Otto, B. 11, 2060).—2. Water produces HClAq and H₂SO₄Aq; a small quantity of water is said to form Cl(SO2.OH)Aq. -3. Excess water is said to form U(SO₂, UH)Aq.—8. Excess of SO₂Cl₂ added to a little alcohol forms C((SO₂, OEt); with excess of alcohol SO₄(OEt)₂ is produced (Behrend, B. 9, 1834).—4. Phosphorus pentachloride reacts to form POCl₃, SOCl₂, and Cl (H. a. K., B. 15, 1736).—5. Phosphorus pentachloride and Collaboration and Cl (H. a. K., B. 15, 1736).—5. Phosphorus pentachloride and Collaboration and Colla SUUL, and UI (H. a. K., B. 15, 1736).—5. Phosphorus, arsenic, and antimony produce Pol, AsCl, and SbCl, respectively, and SO, (H. a. K., l.c.).—6. Ammonia forms NH₂Cl and SO₂NH₂ONH₄.—7. With many organic compounds SO₂Cl₂ reacts like PCl₃ or POCl, substituting Cl for H (v. Dubois, Z. [2] 2, 705; Michaelic 4 170 1) Michaelis, A. 170, 1).

PYROSULPHURYL CHLORIDE $S_2O_3Cl_2 = Cl.SO_2.O.SO_2.Cl.$ (Disulphuryl chloride. Pyrosulphuric oxychloride. Chlorosulphoric anhydride.) Mol. w. 214'38. Boils at 139'59' (Thorpe, C. J. 37, 360; for other determinations v. Rose, P. 44, 291; Michaelis, J. Z. 6, 235, 240, 292; Rosenstiehl, C. R. 53, 658; Schützenberger, C. R. 69, 352). S.G. 70 1.85846, at b.p. 1.60610 (Thorpe, l.c.). V.D. at slightly above b.p. = 104; between 160° and 240° = 54.8 (Heun.p. = 104; between 160° and 240° = 54°8 (Heumann a. Köchlin, B. 16, 470; Kanowaloff, B. 16, 1127; cf. Rosenstiehl, C. R. 53, 658; Rose, P. 44, 201; Ogier, C. R. 94, 82, 217; 96, 648). H.F. [S',O',Cl'] = 180,600 (Kanowaloff, l.c.); Ogier (l.c.) gives 159,400. Heat of vaporisation 7,570 (K., l.c.); 13,160 (O., l.c.). S.H. '258

(K., l.c.). Formation.—1. By the interaction of PCl_s and SO_s or Cl(SO₂.OH).—2. By heating P₂O_s and and SO₂ or Cl(SO₂.OH).—2. By heating P₂O₂ and Cl(SO₂.OH) (Billitz a. Heumann, B. 16, 483).—3. By heating SO₃ with NaCl (R., l.c.), with S₂Cl₂ (Rose, P. 44, 291), with CCl₄ (Schützenberger, C. R. 69, 352; Kanowaloff, C. R. 95, 1284), with C₂Cl₆ (Prudhomme, C. R. 70, 1137), with CHCl₄ (Armstrong, C. J. [2] 1, 244), or with SiCl₄ (Gustavson, B. 5, 332).—4. By the interaction of POCl₂ and SOCl₂ (Michaelis, J. Z. 6, 235, 240, 292). 235, 240, 292).

Preparation.-1. P2O3 and Cl(SO2.OH) are heated in a flask with a reversed condenser, using rather more Cl(SO₂OH) than P₂O₃; when HCl and SO₂ cease to be given off, the liquid is distilled, and the portion coming over between 135° and 145° is fractionated (B. a. H., l.c.).— 2. S.Cl2 in a flask is surrounded by a freezing mixture, and saturated with SO; the product is fractionated; $5SO_2 + S_2Cl_2 = 5SO_2 + S_2O_3Cl_2$ (Rose, P. 44, 291). Thorpe (C. J. 37, 360) found that the product of this reaction boiled almost wholly between 135° and 138°.

Properties and Reactions.—A colourless, mobile, very refractive liquid, fuming in the air with formation of Cl(SO₂,OH).—1. Decomposed by heat to SO₂, SO₂, and Cl (Rose, P. 44, 291); the V.D. determinations of Heumann a. Köchlin tne v.D. determinations of Heumann a. Köchlin (B. 16, 479) show that at 440° the decomposition is $S_2O_2O_1=SO_2+SO_2+Cl_2$.—2. Sinks in water, and is slowly decomposed to HClAq and H₂SO₄Aq; if a very little water is used Cl(SO₂OH) is formed, thus $S_2O_2Ol_2+H_2O$ = 2Cl(SO₂OH) (v. B. a. H., l.c.) — 3. Reacts with phosphorus suphus continuous with phosphorus, sulphur, antimony, copper, iron, sinc, and some other metals, to produce chlorides, SO, and SO, (Heumann a. Köchlin, B. 16, 479).—4. Phosphorus trichloride produces

PCl₃, POCl₃, and SO₂; phosphorus pentachloride forms POCl₃, Cl, and SO₂ (Genther, B. 5, 925). S. Selenion tetrachloride gives SSeO₂Cl₃ (Claus-nizer, B. 11, 2010).—6. Chromates react to form CrO₂Cl₂ (Rosenstiehl, C. R. 53, 658).-7. Ammonia forms a white solid, which dissolves in water, producing NH,Cl and a sulphamate of NH, (Rose, l.c.).

SULPHUR MONOXYTETRACHLORIDE S.OCI. heating equal weights of S₂Cl₂ and SO₂Cl₂ to 250° in a scaled tube, Ogier (Bl. [2] 37, 293) obtained a deep-red liquid resembling S₂Cl₂, S.G. 1.656 at 0°, decomposing under 100° to S₂Cl₂, SO2, and S, to which he gave the composition

S₂OCl₄. Decomposed by water to H₂SO₄Aq, SO₂Aq, HClAq, thionic acids, and S.

SULPHUR TRI-OXYTETRACHLORIDE SOLEHUR THI-OXYTETRACHLORIDE SOLEHUR MOI. w. not determined. This compound was obtained by Millon (A. Ch. [3] 29, 327) by the action of moist Cl on S₂Cl₂ (cf. Marchand, J. pr. 22, 507; Carius, A. 106, 295). It is conveniently propared by the reaction SCl₄+Cl(SO₂OH) = HCl+S2O2Cl; a stream of dry Cl is led into a mixture, in the ratio of equal numbers of molecules, of S2Cl2 and Cl(SO2OH), kept at c. - 20°, until a semi-solid mass is obtained (a very wide tube must be used to lead in Cl); the temperature is then kept at c. -13° and the Cl is continued till the mass gets quite solid; the freezing mixture is then removed, and the Cl is continued till the mass is white, when the excess of Cl is removed by a stream of dry CO, (Michaelis a. Schifferdecker, B. 6, 996).

S2O3Cl4 is a white, crystalline solid, with a most disagreeable odour; the vapour acts on the eyes. Melts at 57°, giving off SO, and Cl, the eyes. Ments at or, giving on 1902 and or, and leaving a liquid that solidifies chiefly to SOCl₂ and S₂O₃Cl₂; a portion sublimes in fine white needles. Ice-cold water produces SO₂Aq, H.SO.Aq, and HClAq; water at the ordinary temperature also separates S. Deliquesces in a partially closed vessel, giving off HCl, Cl, and SO₂, and leaving a liquid that gives SOCl₂ and S₂O₃Cl₂ on distillation. Conc. H₂SO₄ reacts violently, forming HCl, SO₂ and Cl(SO₂OH); CS₂ reacts violently, forming HCl, SO₂ and Cl(SO₂OH); CS₂ produces very rapid decomposition to COCl₂, CO, SO₂, S.Cl₂, and SOCl₂. On long standing in a closed tube S₂O₃Cl₄ separates into equal numbers of molecules of SOCl₂ and SO₂Cl₂ (M. a. Mathias, B. 6, 1452).

M. M. P. M. PHIDES, p. 655. SULPHUR, OXYACIDS OF. Several acids have been isolated, and salts of some others are known. The following list gives the names and compositions of the oxyacids of sulphur and their salts, with references to the articles where these compounds are described :-

HYPOSULPHUROUS ACID AND SALTS H2S2O4 and M.S.O.; v. Hyposulphurous acid under Sulphurous Acid (p. 627), and hyposulphites under Sul-

ритив (р. 592).

SULPHUBOUS ACID AND SALTS H2SO, MHSO, and M.SO.; v. SULPHUROUS ACID (p. 626), and Виденетая (р. 587).

SULPHUBIC ACID AND SALTS H,SO, MHSO, and M2SO4; v. Sulphuric acid (p. 620) and Sulphares (p. 567).

THIOSULPHURIO ACID AND SALTS $H_2S_2O_2$, MHS_2O_3 , and $M_2S_2O_3$; v. THIOSULPHURIO ACID (p. 708) and THIOSULPHATES (p. 705).

THIONIC ACIDS AND SALTS H.S.O., H.S.O. $H_2S_1O_6$, $H_2S_3O_6$ (and salts); v. Thionic acids (p. 698) and Thionates (p. 695).

Pyrosulphuric acid and salts H.S.O., MHS.O., and M.S.O.; v. Pyrosulphuric acid under Sulphumo Acid (p. 625), and Pyrosulphates under Sulphates (p. 583).

PERSULPHURIC ACID AND SALTS H.S.O.Ag. M.S.O., and MS.O.; v. Persulphuric acid under Sulphuric acid (p. 625), and Persulphates under Sulphates (p. 582). M. M. P. M.

SULPHUR OXYACIDS, NITROGEN DERI-VATIVES OF. In 1845 Fremy (A. Ch. [3] 15, 408) described the K salts of a number of acids obtained by the interaction of KNO,Aq and K,SO,Aq, and by boiling the products of this interaction with slightly acidified water; he called the compounds salts of sulphazotised acids. The examination of these salts was prosecuted by Claus a. Koch (A. 152, 336 [1874], and by Claus (A. 158, 52, 194 [1876]); Berglund (Bl [2] 25, 455; B. 9, 252, 1896 [1875]); and Raschig (A. 241, 161; B. 20, 584 [1887]) also investigated the sulphazotised acids of Fremy; and the researches of Divers and Haga (C. J. Trans. 1885, 1886, 1889, 1892) have thrown much light on many classes of these compounds. The more recent investigations noted above have shown many of the formulæ given by Fremy to be inaccurate, and they have also led to a considerable revision of Claus's results. As the compounds that have been fairly thoroughly examined are noticed under the heading Sulphonic ACIDS AND DERIVATIVES (p. 509), it does not seem necessary to give an account of the other salts of sulphazotised acids, especially as it is very probable that the formula assigned to these compounds will require modification, and that some of the compounds will be found not to exist.

The chief sulphazotised compounds that have been investigated sufficiently to establish their composition satisfactorily are the following:-

Amidosulphonic acid and salts NH2(SO2.OH) described as Sulphamic acid (p. 567).

Imidosulphonic acid and salts NH(80,0H), (p. 600).

Nitrilosulphonates N(SO, OM), (p. 601).

Nitrosulphonic acid and salts NO2(SO2.OH) (p. 601).

Nitrosulphonic anhydride (NO₂), 8,0, (p. 601). Nitrosulphonic chloride NO₂(SO₂Cl) (p. 601). Nitroso-oxy-amidosulphonates N(NO.OH)(SO2-OM); described nitroso.

sulphates under Sulphates (p. 581).

SULPHURIC ACID; also PERSULPHURIC ACID and PYROSULPHURIC ACID.

SULPHURIC ACID H₂SO₄ (Oil of vitriol).

Mol. w. probably 97.76. Melts at 10.35° (Pickering, C. J. 57, 331); 10.5° (Thilo, Chem. Zeitung, 16, 1688). Boiling begins at c. 290°, SO₄ and H₂O with some H₂SO₄xH₂O passing off; b.p. rises till 338° is reached, when it becomes constant and complete dissociation to SO₄ and H₂O occurs; for b.p. of H₂SO₄Aq from 95 to 5 p.c. H₂SO₄ v. Lunge (B. 11, 370). S.G. ¹⁸⁵_{12°} 1.8884 (Perkin, C. J. 63, 59; cf. Pickering, C. J. 57, 73, note; Rohlrausch, W. 17, 69; Schertel, J. pr. [2] 26, 246; Mendeléeff, B. 17, 30, 2536; Lunge a. Isler, Zeit. für anorg. Chemie, 1890. 129). V.D. 25 at 440°, corresponding with dissociation to SO₄ + H₂O (Deville a. Troost, C. R. 56, 891; Wanklyn a. Robinson, Pr. 12, 507). SH. (22° tq 80°) 355; (22° to 170°) 37 (Pfaundler, B. 3, 798); (16° to 20°) 3315 (Marignao, Ar. Sc. 39, 217, 273). C.E. 0005585 at 20° (Marignac, Lo.). H.F. [H²S,O⁴] = 192,920; [H²O, SO³] = 21,320 (formation of liquid H₂SO₂) (Th. 2, 255). Heat of fusion = 860 g. units (for 98 g. H₂SO₂) (Berthelot, C. R. 78, 716). T. C. v. Beetz (W. 7, 435), Weber (J. 1885. 121). μ-1. Mol. w. = 32.45 (Gladstone, P. M. [4] 36, 311). For further data v. infra.

Occurrence. — Small quantities of H.SO., from 1 to 5 p.c., are found in some rivers and springs in volcanic districts; in a pool in Texas, Mallet (C. N. 26, 147) found 5 29 g. H.SO. per litre of water. The acid is also found in certain animal secretions; the salivary glands of some molluses are said to contain c. 2 p.c. (Bödeker a. Troschel, B. B. 1854. 486; De Luca a. Panceri, Bl. [2] 9, 400; Maly, M. 1, 205). The salts of splutneric acid occur in large quantities (v. Sulphares, p. 567).

Formation.—The formation of an oily liquid by heating alum is spoken of by Geber in the eighth century; a similar liquid was formed in the fifteenth century by burning sulphur with saltpetre. These liquids were shown to be identical towards the end of the sixteenth century. Oil of vitriol seems to have been manufactured in fair quantities by heating ferrous sulphate from about the early part of the eighteenth century; the first manufactory for making the acid from sulphur was started at Richmond by Ward about 1740. The composition of sulphuric acid was determined by Lavoisier.

1. By long exposure of flowers of sulphur in the air (John, S. 14, 417; Wagenmann, P. 24, 601).—2. By heating S with H_{*}O to c. 200°; by electrolysing H_{*}O, using Pt electrodes with pieces of S attached, the H_{*}SO, forms at the positive pole (Becquerel, C. R. 56, 237).—3. By the oxidation of S in presence of H_{*}O by Cl, HNO_{*}, HCl and KClO_{*}, aqua regia, &c.; also by certain metallic salts (v. Wicke, A. 82, 146; Parkmann, Am. S. [2] 33, 328).—4. By oxidising SOAq or SO_{*} in presence of water, by Cl, Br, H_{*}O_{*}Aq,

NO., HNO., &c.; by passing moist SO., and air over hot Pt black (Phillips, A. 4, 171), through a red-hot tube containing pieces of glass (Magnus, P. 24, 610), or over red-hot sand (Blondeau, C. R. 29, 405).—5. By the oxidation of H_sS and polythionic acids (v. Cloëz a. Guignet, C. R. 46, 1110).—6. By the interaction of water and SO., SO.₂Cl., SO., Cl.OH, &c.

Preparation.—Commercial oil of vitriol is diluted until the S.G. is 1.53 (=50° Beaumé, or 106° Twaddell, =62.5 p.c. H₂SO, by weight); the acid is heated to 70°-80°, and Na₂S₂O₃ is added in quantity sufficient to decompose the As2O, present (which should be estimated beforehand), according to the equation $3Na_2S_2O_3 + As_2O_3 = 3Na_2SO_4 + As_2S_4$; the acid is stirred until the As, S, separates in flocks (Thorn, D. P. J. 217, 495); the acid is filtered from As S. through asbestos or glass-wool, and is then concentrated by evaporation in a Pt dish till it begins to fume, and then in a retort of Pt or hard glass. The cone, acid is now heated with a little pure (NH₁)₂SO₁, whereby HNO₂ and HNO₃ are decomposed (NH₄,NO₂ and NH, NO₃ are formed, and then decomposed to N and H₂O, and N₂O and H₂O). The acid is then distilled from a glass refort, heated by a ring-burner placed around the retort at about two-thirds of the distance from the level of the acid to the bottom of the retort. The distillate is re-distilled in small quantities from a Pt retort into a Pt receiver; the condenser being formed of Pt tubes, soldered with gold and fitting closely one into the other, and the temperature being such that the acid does not boil during the distillation (cf. Stas, Chem. Proport. 112). Various other methods for removing As have been proposed; for the preparation of H2SO, free from As for chemico-medical use v. Bloxam (C. J. 15, 52), also Buignet a. Bussy (J. Ph. [3] 44, 177; 46, 252).

Commercial oil of vitriol is prepared by passing SO₂, mixed with a little IINO₃, into large leaden chambers into which jets of steam are also sent. The SO₂ is prepared by burning S or pyrites in a stream of air; the hot gas is passed over HNO₃, or over pots containing KNO₂ and H₂SO₄, so that it sweeps into the leaden chambers a certain quantity of HNO₂. The interactions between the hot SO₂ and HNO₃ probably produceNO and N₂O₃(3SO₂ + 2HNO₄ + 2H O = 3H₂SO₄ + 2NO; and also 2SO₂ + 2HNO₄ + 2H O = 2H₂SO₄ + N₂O₃); the NO then combines with O in the air of the chambers to form N₂O₄(4NO + O₂ = 2N₂O₃), which interacts with SO₂ and H₂O to produce H₂SO₃ and NO(N₂O₄ + SO₄ + H₂O = H₂SO₄ + 2NO) :—if N₂O₄ is produced in the primary reaction of SO₂ with HNO₃, this N₂O₃ may take up O to form N₂O₃, which in turn may react with SO₂ and H₂O to produce H₂SO₃ and NO(N₂O₄ + 2NO). These cycles of changes proceed as long as SO₄ is sent into the chambers, and there is present a sufficient Of O₂, and SO₂ (or N₂O₃ and SO₂ (or N₂O₄ + 4NO; or SN₂O₄ + 4SO₂ + 2H₂O = 4NO₄(SO₂OH) —is formed as a solid on the sides of the chamber (3N₂O₄ + 2SO₂ + H₂O = 2NO₂(SO₂OH) + 2NO₄ (SN₂O₄OH) + 2NO₄ SN₂O₄ + 4SO₄ + 2H₂O = 4NO₄(SO₂OH) + 2NO₄

when steam is now sent into the chamber the nitrosulphonic acid is decomposed to H,SO_3 and N_2O_3 ($2NO_3$ (SO_2 .OH) + $H_2O=2H_3SO_4+N_2O_3$). It is possible that the formation of NO_3 (SO_2 .OH) and the interaction of this with water may form normal stages in the series of reactions that occur in the chambers. Lunge (C.J.47, 405) regards N_2O_3 as the chief carrier of O from the air to the SO_3 ; he formulates the two main interactions as

$$\begin{array}{ll} \textbf{(1)} & 2SO_2 + N_2O_3 + O_2 + H_2O = 2NO_2(SO_2.OH), \\ \textbf{(2)} & 2NO_2(SO_2.OH) + H_2O = 2H_2SO_4 + N_2O_3; \end{array}$$

moreover, he insists that the interactions take place for the most part between gases in contact with the surface of the vesicles of liquid water formed by the condensation of the steam sent into the chamber. (A fuller discussion of the reactions that occur in the leaden chambers will be found in the DICTIONARY OF APPLIED CHEMISTRY, vol. iii, p. 726.)

Some portion of the oxides of N is swept through the chambers and so lost (part of this is recovered in the Gay-Lussac towers); some is lost by leakage, solution in the acid formed in the chambers, and in other mechanical ways; but some portion of the available oxides of N is also destroyed by secondary reactions that occur in the chambers, and result in the formation of N₂O and sometimes of N or NH₃(v. Weber, P. 130, 329; Pelouze, A. Ch. [2] 60, 162; Lungo, B. 14, 2196; cf. Dictionary of Applied Chemistry, vol. iii. p. 729).

Properties .- A clear, colourless, oily, hygroscopic liquid; solidifying at c. 10.5°. The liquid may be cooled much below its freezing-point without solidifying, but addition of a crystal of H2SO, or a small quantity of SO, causes crystallisation; the presence of a trace of water lowers the freezing-point to c.0°. II SO, is exceedingly acrid and burning, and is a violent poison. H2SO, fumes very slightly in air at the ordinary temperature: at 30°-40° it fumes much, giving off SO₃; according to Colefax (C. N. 63, 179), H₂SO₄ is probably slightly volatilised at ordinary temperatures. The mol. w. of H₂SO₄ has not been determined directly, but from the mol. weights of such derivatives as SO2Cl2, SO, (OMe), &c., the formula H.SO, is most probably molecular. H,SO, is decomposed when heated, and does not show a definite b.p.; boiling begins at c. 290°, and the temperature gradually rises to 338°, at which temperature dissociation to H₂O and SO₂ is complete. The residue has the composition H₂SO₄-T₂H₂O; acid with this composition is obtained by boiling down either H.SO., 2H.O or H.SO., 2SO. (Marignac, A. Ch. [3] 89, 184; Dittmar, C. J. [2] 7, 446). The sp. tr. of the vapour given off at c. 440° corresponds with that calculated for the dissociation of H₂SO, into SO₁+H₂O (Deville a. Troost, C. R. 56, 891; Wanklyn a. Robinson, Pr. 12, 507). The b.p. of H₂SO₄A₁ containing from 95 p.c. H₂SO₄ (b.p. 295°), to 5 p.c. H₂SO₄ (b.p. 101°) is given by Lunge (B. 11, 370). H₂SO₄ freezes at 10·352° (v. Pickering, C. J. 57, 10°). 831; where a long series of determinations is given of f.p. of H₂SO₄Aq containing from 005 to 100 p.c. H₂SO₄). The S.H. and mol. heat $(=8.H.\times98)$ are given by Pfaundler (B. 8, 798) às follows :

Temp. interval	and the second	222 5
from 22° to	8.H.	Mol. neat.
80°•	·855	84.790
90	·856	84.888

140	.864	85.672
150	•365	85.770
160	-367	85.966
170	.870	86:260

For S.H. of H.SO, xH,O from 16° to 20°, varying from 0 to 400, v. Marignac (Ar. Sc. 8) 217, 273); Bode (Zeit. filr anorg. Chemie, 1885. 244) gives S.H. of H₂SO₄Aq from S.G. 1.842 to 1.037; Pickering (C. J. 57, 160) gives S.H. of H₂SO₄Aq from c. 2 to c. 12 p.c. H₂SO₄ dissolves in water in all proportions; much heat is produced, and contraction occurs; for thermal measurements v. Thomson (Th. 3, 44), Favre a. Silbermann (C. R. 24, 1081), F. a. Quaillard (C. R. 50, 1150), Plaundler (J. 1869, 122), and, especially, Pickering (C. J. 57, 164). According to Pickering (C. N. 64, 14), the maximum contraction, calculated for unit weight of solution, changes from 67 p.c. at 8°, to 70.1 p.c. at 38°; but the maximum is constant at 76 p.c., from 8° to 38°, if calculated for unit volume; for fuller data v. P. (C. J. 57, 148). The expansion to 400, xH₂O, at 20°, when x varies from 0 to 400, is given by Marignac (Ar. Sc. 39, 217, 273). The refractive indices and dispersion of H₂SO₂Aq containing from 93.87 to 088 p.c. II.SO, are given by Pickering (C. J. 63, 99; cf. van der Willingen, Ar. N. 3, 122). Perkir (C. J. 63, 57) gives Mol. R. for H.SO, Aq from 99.92 to 9.18 p.c. H₂SO₄ (= from H₂SO₄ + 53.87 H₂O to H₂SO₄ + .004 H₂O).

The electrical conductivities of H_sSO_sAq of different concentrations have been measured by Kohlrausch (P. 154, 215, 159; 233; W. 6, 1; 17, 69), also by Pickering (C. J. 57, 158), who gives determinations for H_sSO_sAq containing from 1 to 100 p.c. H_sSO_s (v. also Bouty, C. R. 108, 393; also Grotrian, P. 151, 378).

The S.G. and composition of H₂SO₄Aq of varying concentrations have been determined by many observers. Pickering (C. J. 57, 152) gives S.G. and composition of H₂SO₄Aq containing from 5 to 100 p.c. H₂SO₄ at 0°, 2°, 4°, and each 2° up to 40°. Lunge a. Isler (Zeit. flur anorg. Chemic, 1890. 129) give the following tables (cf. Mendeléeff, ZeP. C. 1887, 273; Pickering, C. N. 64, 311; Lunge, C. N. 65, 13):—

For the properties of fuming H₂SO₄ v. Pyrosulphuric acid, p. 625.

For a test for small quantities of free H₂SO₄ v. Carey Lea (Am. S. [8] 45, 478; abstract in C. J. 64 (ii.), 566).

Reactions. -1. Conc. H2SO4 is decomposed

by heat; at c. 440° the products are SO, and H₂O, and by passing through a red-hot tube SO,, O, and H₂O are formed (Deville a. Troest, C. R. 56, S91; Wanklyn a. Robinson, Pr. 12, 507, Redwood, Ph. [2] 5, 601; Deville a. Debray, A. Ch. [3] 61, 125),—2. Decomposed by the electric current; with conc. H₂SO, and a raised temperature O separates at the positive pulc temperature O separates at the positive pole, and H and S at the nogative; at 0° only H and O are given off (Faraday, T. 1834; Warburg, P. 135, 114; Luckow, Fr. 1880, 1; Berthelot, C. R. 86, 71; 90, 269). Gladstone a. Tribe (C. J. 85, 176; 43, 345) found that a little SO, was formed when the electrolysis of 98 2 p.c. H₂SO, was very slow. According to the concentration of the II.SO.Aq electrolysed, the strength of the current, and the current density, ozone, H2O2, and S2O, are formed, besides H and O. For an examination of the conditions favourable to the production of ozone v. McLeod (C. J. 49, 591, where references are given to earlier memoirs). According to Botty (C. R. 108, 393), acid of the concentration H₂SO₄ + H₂O always gives H₂O₂ on electrolysis; Richarz (A. Ch. [2] 24, 183) obtained with acid of the concentration $H_2SO_4 + 1.347H_2O$; with acid more dilute than O p.c. H_2SO_4 very little H_2O_2 is obtained, but considerable quantities of S_2O_2 and ozone (Bouty, l.c.; cf. Kuriloff, J. R. 23, 235). In connection with the electrolysis of H₂SO₄Aq, and the conditions of production of H and O only, or of Holo, coone, and S₂O, also, v. Armstrong (C. J. Proc. 1893-4. 188 [No. 127]).—3. By passing a mixture of the vapour of H₂SO₄ mixed with hydrogen through a red-hot tube, H₂O is obtained along with SO₂, S₁ or H₂S₂ according to the quantity of H (v. Warner, C. N. 28, 18). Hydrogen occluded by palladium or platinum Hydrogen occurate of pattachem or patterns partially reduces 98.2 p.c. H₂SO₃, giving SO₄ (G. a. T., l.c. p. 177).—4. SO₃, CO₄, and H₄O are formed by heating conc. H₂SO₄ with carbon; and SO₂ and H₂O by heating with sulphur.—5. Phosphorus takes fire in boiling H₂SO₄ with separation of S; red phosphorus reacts with the conc. acid when hot, forming SO, and H.PO. -6. Chlorine reacts with conc. H2SO, to form Cl(SO₂.OH) (v. Chlorosulphonic acid, p. 509).—7. Most metals interact; K and Nagive off H, Zn and Fe and several other metals also give off H with more or less dilute H.SO.Aq at ordinary temperatures; on raising the temperaordinary temperatures; on raising the tempera-ture SO₂ and H₂S are generally evolved and S is often separated. Some metals, such as Sb, Bi, Cu, Hg, react only with warm fairly cone. H₂SO₄. Cu, Hg, react only with warm fairly cone. H₂SO₂, giving off SO₂, and often also H₂S. Au, Ir, Pt, Rh, and W do not interact with H₂SO₄. Regarding the conditions of the interaction of H₂SO₄ad with metals—concentration, temperature, and products—v. Ditte (A. Ch. [6] 19, 68). Pattison Muir a. Adie (C. J. 53, 47) found that the only products of the interaction of approximately pure zinc and dilute H₂SO₄Aq (c. H₂SO₄.12H₂O to c. H₂SO₄.15H₂O) were ZnSO₂Aq and H; that with cone. acid (c. H₂SO₄.H₂O to c. H₂SO₃ SO₂ was the chief gaseous product, and that H₂S was also produced at higher temperatures; and that with acid of intermediate concentration (c. H₂SO₄.2H₂O) both SO₂ and H₂S were formed in considerable quantities at c. 160°. For experiments on the rate of action of H₂SO₄Aq ox periments on the rate of action of H.SO.Ag on

different specimens of zinc v. Divers a. Shimidzu (C. J. 47, 598), who have also examined the production of NH₂OH by the interaction of zino with H₂SO₂Aq and HNO₂Aq together (cf. Hydroxymanne, vol. ii. p. 734). For qualitative the control of the control of the superscript of the sup tive experiments on the interaction of H₂SO₄ and tin, v. Pattison Muir a. Robbs (C. N. 45, 69, where references to other memoirs are given). Pullinger (C. J. 59, 815) found that pure zinc was not acted on by H₂SO₂Aq (1 part conc. acid + 3 parts water by weight) provided the acid had been boiled for a long time before use and the surface of the zinc was quite smooth; if the surface was rough some of the zinc was dissolved. P. also found that oxidisers increased the rate of solution of zinc, and reducers, if not containing S, almost stopped the solution. P. concluded that when the surface of the zinc was rough S₂O₇ was probably formed, and then the action proceeded. Weeren (B. 24, 1785) noticed that there was scarcely any reaction between pure zinc and H₂SO₄Aq (c. 20 parts water); he supposed that a layer of H was condensed on the surface of the metal. W. thought that with impure zinc the H is given off from the surface of the more negative metal present, and so the surface of the zinc is left exposed to the action of the acid. W. found that the evolution of H proceeded more rapidly in vacuo, and that it was hastened by brushing the surface of the metal. The weight of pure zinc dissolved in 30 mins. was 2·1 mgm. at 0°, 9·3 mgm. at 98°, and 122·1 mgm. at the b.p. of the acid used. W. obtained similar results with Al, Cd, Co, and Fe. Sodium amalgam or zinc amalgam, with conc. HaSO, amalgam or zinc amalgam, with conc. H.,SO,, gives off H, then quantities of H.,S, then SO, and S, and finally only SO, (Walz, C. N. 23, 245). The interaction of H.,SO, and copper has been fully examined by Pickering (C. J. [2] 18, 112; of. Copper, vol. ii. p. 253).—8. H.,SO, reacts with the caides of nitrogen (not with N.,O) to form NO, (SO, OH) (v. NITROSULPHONIC ACID, p. 601).—9. Phosphoretted hydrogen reacts slowly with H.SO. at the ordinary temperature, giving SO, S. Phosphotetet hydrogen teach slowly with H₂SO₂ at the ordinary temperature, giving SO₂, S, and H₂PO₄ (Rose, P. 24, 139)—10. With sulphuretted hydrogen, H₂O₅ S, and SO₂ are formed .- 11. Phosphorus pentoxide withdraws H₂O from hot conc. H₂SO₄, producing P₂O₃.H₂O and SO₄ (Barreswil, C. R. 25, 30; Evans, Ph. 8, 127); phosphorus pentaciloride or trichloride forms 80, and POCl, also 80, Cl, when PCl, is used (Williamson, P. M. [4] 7, 365; Schiff, A. 202, 111; cf. Michaelis, J. Z. 6, 233, 292), and also Ol(80, OH) (Müller, B. 6, 277; Ceuther, B. 5, 278) 925; Thorpe, C. J. 37, 358).—12. H₂SO, reacts with most salts to form sulphates, and set free the said of the salt if that said is more volatile than H.SO.. In several cases secondary reactions occur between the acid set free and the H.SO.; thus, with bromides and iodides, Br and I, and SO, or H.B, are produced. The interaction of H.BO.Aq and KBr has been examined by Addyman (C. J. 61, 94), who found that the percentage of HBr decomposed varied almost directly with the quantity of H₂SO₄ used, and that when so much H₂SO₂ was present that the water produced in the reaction 2HBr + H₂SO₄ = 2H₂O + SO₂ + Br₂ caused no sensible dilution of the H₂SO₄ all the HBr was decomposed; with dilute acid, c. 30 p.c. H.SO, using excess of acid, scarcely a trace of HBr was decomposed (cf. Feit a. Kubierschki,

J. Ph. [5] 24, 159). Jackson (C. J. 43, 839) finds that the interaction of conc. H.SO, and KI varies according as the acid is present in large excess, or in quantity just sufficient for the KI used. In the first case all the I of the KI is set free along with an equivalent quantity of SO; in the second case all the I is liberated with the equivalent quantity of H2S. Many salts of acids containing much oxygen, e.g. dichromates and permanganates, are decomposed by hot conc. H.SO, with evolution of O. The reaction of H.SO, Aq with KMnO, Aq has been examined by Gooch a. Danner (Am. S. [3] 44, 301), who found that the quantity of O given off increased with (1) concentration of H.SO.Aq, (2) time, (3) temperature; no O was given off after a few hours with 20 p.c. acid at the ordinary temperature, but a considerable quantity of O was produced after five days' action, and c. the same result was obtained by heating to 80° for one and a half hours (cf. Jones, C. J. 33, 95).— 13. Conc. H.SO, reacts with many oxygenated organic compounds, withdrawing H,O; with benzenoid hydrocarbons it forms sulpho-acids; many organic compounds, such as sugar, starch, &c., are charred by warm H₂SO₄.—14. Pictet (C. R. 115, 708, 814) has examined the reactions of sulphuric acid at low temperatures, using acid of 89 p.c. H.SO.; no action occurred below -125° with such bodies as NaOH, NaCl, NH., Na₂CO₃, Na, K; in most cases action began suddenly at temperatures varying from - 120° to -60°.—15. H₂SO₄ combines with water; the hydrates H₂SO₄.H₂O₅ H₂SO₄.2H₂O₅ and hydrates H₂SO₄.3H₂O have been isolated as solids (v. infra).—16. Conc. H.SO, combines with sulphur trioxide to form H.SO, SO, and other compounds (v. Pyrosulphuric acid).

For the reactions of fuming H.SO, v. Pyro-SULPHURIC ACID (p. 625). The salts of H2SO4 are described under Sulphates (p. 567). Both amides of H2SO, viz. SO2OH.NH2 and SO2(NH2)2, have of H.SO., VIZ. 502.0H.MI. Bull SO.(H.H.), have been isolated (v. SULPHAMIC ACTD, p. 567, and SULPHAMICA CUT), p. 567, and SULPHAMIDE, p. 567); the imide SO.,NH is also known, v. SULPHAMIDE, p. 587; cf. also SULPHAMIDE NH(SO.,NH.), p. 587, and IMIDO-MULPHONIO ACID NH(SO.,NH.), p. 587, and IMIDO-SULPHONIO ACID NH(SO.,NH.), p. 600.

Constitution of sulphuric acid.—The reactions of H₂SO₄ with Cl and with PCl₃, and the reactions of the products with water, also the formation of SO₂.OH.NH₂, SO₂(NH₂)₂, and SO₂NH, show that H₂SO₄ contains two OH groups. The fact that only one compound, SO. OEt.OMe, can be formed from H.SO. shows that the two OH groups in SO2(OH), are related to the rest of the molecule in the same way; hence the formula for the acid is to be written $\rm S{<}^{O.OH}_{O.OH}$ or $\rm O_2S{<}^{OH}_{OH}$. Inasmuch as $\rm SO_2Cl_2$

is formed from SO₂(OH)₂ by the reaction of PCl₃, as certain hydrocarbons interact with SO₂Cl₂ to form SO₂R₂ (where R = Me, Ph, &c.), and as these compounds SO₂R₂ are reduced to SR, where the radicles R are certainly in direct union with S, it is extremely probable that the OH groups in SO₂(OH)₂ are in direct union with

S, and hence the formula O₂S CH is to be pre-

ferred to S < O.OH for sulphuric acid. It is

HYDRATES OF SULPHURIC ACID. Two solid hydrates have been isolated; a liquid hydrate has probably also been isolated.

Monohydrate H.SO. H.O (Tetrahydroxy-sulphuric acid SO(OH),). Large, colourless, six-sided tablets; formed by mixing 1 part conc. H.SO, with rather less than one-fifth part water (by weight), and surrounding with a freezing mixture. The crystals melt at 7.5° (Pierre a. Puchot, A. Ch. [5] 2, 164). The hydrate readily remains liquid considerably below its m. p. S.G. $\frac{1}{20}$ = 1.7943 (for the liquid) (Mendelceff, B. 19. 880); 1.77806 at 15°, 1.77423 at 20°, 1.77071 at 25° (Perkin, C. J. 49, 777; determinations made with liquid, and referred to water at same temperatures). Thomsen gives H.F. from liquid H₂SO₄ and H₂O [H²SO',H²O] = 6,379 (Th. 3, 54); Berthelot gives 6,120 (C. R. 78, 716). Heat of fusion = 3680 g. units (for 116 g.) H₂SO₄H₂O (Berthelot, C. R. 78, 716). For vapour pressures from 143° to 204° v. Tate (P. M. [4] 26. 502).

Dihydrate H₂SO₄.2H₂O (Perhydroxysulphuric acid S(OH)_d). Formed by adding 368 parts H₂O to 1 part pure H₂SO₄, by weight. This hydrate has not been obtained as a solid; the S.G. of the liquid at 60 is given by Mendelceff

(B. 19, 380) as 1.6655 (cf. Perkin, C. J. 49, 777). It is stated (v. Mendelceff, B. 19, 388) that the maximum contraction when H₂SO₄ and H₂O are mixed occurs when the compounds are present in the ratio H.SO,:2H.O, but Pickering (C. J. 57, 84) says that the maximum does not correspond with the composition of any hydrate the existence of which is indicated in other

ways.

Tetrahydrate H.SO.,4H.O. Obtained by Pickering (C. J. 57, 339) as a crystalline solid, melting at -25°, by cooling H.SO.,4q containing 57.6 p.o. H.SO., (H.SO.,2H.O corresponds with 57.66 p.o. H.SO.). The crystals are large and well defined, and resemble H.SO.,H.O.; the compound may be kept liquid at 20° to 25° below its freezing point.

Hydrates of sulphuric acid in aqueous solution .-- According to Mendeleeff (B. 19, 380; cf. his Principles of Chemistry, vol. ii. p. 234), an examination of the connections between the concentration of H.SO.Aq and the S.G. indicates the existence of hydrates that have not yet been isolated. Pickering (C. J. 57, 64) comes to the same general conclusion from an extended examination of the connections between the changes of composition of H2SO, Aq and the changes of S.G., heat capacity, electrical conductivity, heat of solution, and expansion by heat of the solution. Pickering's reasoning is a special case of that explained in the article Solutions (part ii. p. 492); for the detailed argument, and criticisms of it, v. Peckering, C. J. 57, 64; Rücker, P. M. [5] 32, 304; 33, 204; P., P. M. [5] 33, 132, 463; cf. Mendeleeft, Z. P. C. 1, 275; and Crompton, C. J. 53, 116.

PERSULPHURIC ACID H.S.O.Aq. seid is present in the solution obtained by elec-You IV.

undecided whether the group SO₂ in O₂S.OH.OH | trolysing H₂SO₂Aq of certain concentrations; Berthelot (O. R. 90, 269; 112, 1461) obtained a quantity of the soid equal to from 88 to 123 g. S₂O, per litre by electrolysing H₂SO₂Aq containing water and acid in the ratio 10H₂O:H₂SO₄ (cf. SULPHURIC PEROXIDE, p. 616; and SULPHURIC ACID, Reactions, No. 2, p. 623). According to Traube (B. 22, 1518, 1528) a solution of H₂SO₂ in H₂SO₄ does not oxidise H₂CO₂, HNO₂ CO₃ or Cr₂(SO₄); Richarz, however (B. 21, 1670), says that oxadic and nitrous acids are oxidised. The acid has and introus acids are existing. The acid has not been isolated; by electrolysing at temperatures below 0°, and then adding BaOAq or KOHAq, the Ba or K salt is obtained. The formula H.S.O. is given rather than HSO. because of the results of Bredig's measurement of the conductivities of solutions of the K salt. For salts of this acid v. Persulphates.

> PYROSULPHURIC ACID ILS.O. sulphuric acid). A solution of this acid in H.SO, is know, as funing sulphuric acid, or Mordhausen acid. This acid is obtained by adding rather more SO, to H.SO, than the proportion SO,:H.SO, cooling, and spreading out the crystals that form over meanly conc. H.SO, under a bell-jar till the excess of SO, is removed (Schultz-Sellack, B. 4, 109). Forms large crystals, melting at 35°. Easily decomposed by heat to H₂SO, and SO, H₂S₂O, is dibasic, forming salts MHS₂O, and M₂S₂O, (v. PYROSULPHATES, p. 583). Funing sulphuric acid is a solution of H₂S₂O, in H₂SO₄; it is prepared by heating dry FeSO, in fireday vessels and collecting the oily, fuming liquid that distils over. The acid fumes strongly in the air, and gives off SO₃ whon warmed. But few of the reactions described for pyrosulphuric acid, or for fuming sulphuric acid, can be set down as belonging to a definite compound, but rather to belonging to a definite compound, but rather to solutions of H.S.Q., (and perhaps other compounds of H.S.Q., and SO.) in H.SQ. Finely-divided silver dissolves easily; the solution poured into water gives Ag.SO. and SO.; mercury reacts similarly; spongy copper has a slight reaction, giving Cu.S and CuSO. (Divers a. Shimidzu, C. J. 47, 636). Distilled with phosphorus pentoxide in a stream of hydrogen chloride, Cl(SO.,OH) is formed; the same soid is formed by heating with PCl. and also hy heating chloride, Cl(SO₂OH) is formed; the same soid is formed by heating with PCl₃, and also by heating 'crystallised funing sulphuric soid 'with HCl (v. Силовозиленоми аси, р. 509). Nitrogen dioxide passed into well-cooled pyrosulphuric acid gives NO₂(SO₂OH) (v. Nitrosoulphuric acid gives NO₂(SO₂OH) (v. Nitrosoulphuric acid, p. 601). By saturating ordinary conc. H₂SO₄ with SO₃ (Jacquelain, A. Ch. [3] 30, 343), or by cooling fuming H₂SO₄ to -10° (Wackenroder, Ar. Ph. [3] 87, 267), the compound H₂SO₂,2H₂SO₄ (-3H₂SO₄,SO₉) is said to be obtained in transparent crystals. Schultz-Sellack tained in transparent crystals. Schultz-Sellack (B. 4, 109) failed to obtain any compound of H₂SO₄ and SO₃, except H₂SO₄. Crystals of the composition H₂SO₄.3SO₄ (=H₂S₁O₁) melting at 8°-10° are said by Weber (P. 159, 313) to be formed by adding cooled conc. H_SO₄, little by little, to SO₄.

SULPHURIC PEROXIDE S₂O, v. p. 616. SULPHUROSAMIC ACID SO.OH.NH₂ v

THIONAMIC ACID, p. 695. SULPHUROUS ACID and HYPOSUL-

PHUROUS ACID.

SULPHUROUS ACID H₂SO₄Aq. The acid has not been isolated; a solution of SO₂ in water reacts as a weak dibasic acid, forming salts of the types M'HSO₃, M'₂SO₃, and M'HSO₃ (v. SULPHITES, p. 587). H.F. [H'₂S,O'₂Aq] = 147,130; [H'₂O,S,O'₂Aq] = 78,780 (from rhombic S; Th. 2, 251).

The methods of formation and preparation of H₂SO₂Aq are sufficiently detailed under SUL-PHUE DIOXIDE (p. 613); it is only necessary to add water to the SO₂ obtained.

Properties.—An aqueous solution of H₂SO₃ readily decomposes, giving off C'₃; on standing for some time in the air, and more quickly by warming, H₂SO₄Aq is formed with production of much heat; [H'SO'Aq, O] = 63,634 (Th. 2, 253). H₂SO₃Aq is altered by the action of light, so that after exposure to light for some time the solution ppts. Ag₂S from AgNO₂Aq, and reduces silver haloid compounds, forming some Ag₂S; the solution after exposure to light behaves like a dilute solution of a polythionic acid (Stas, Chem. Proport. 64). Löw (L'Institut, 1873. 67) says that dilute H₂SO₄Aq is changed to H₂SO₄Aq is changed to H₂SO₄Aq is changed to H₂SO₄Aq

and S by long exposure to light.

Reactions.—1. Heated in a closed tube to 170°—180°, H.SO,Aq and S are formed, and after a time also H.S (Geitner, A. 129, 350).—2. Decomposed by an electric current, giving H.SO,Aq at the positive pole and S at the negative; with a weak current H.S.O,Aq is probably formed at first at the negative pole (Guéroult, C. R. 85, 225).—3. Phosphorus pentachloride produces SOCU, and POCI, (Kremers, A. 70, 297; Schiff, A. 102, 111).—4. Sulphurous chloride with H.SO,Aq produces polythionic acids (v. Debus, C. J. 53, 345).—5. Vapour obtained by heating H.SO,Aq produces with chlorine, when passed over red-hot Pt, to form Cl(SO,OH) (v. Chlorosulphonic acid, p. 599).—6. NO₂(SO₂,OH) (v. NITROSULPHONIC ACID, p. 601) is formed by the interaction of moist SO₂, i.e. H.SO,Aq, with mitric oxide or mitrogen dioxide.—7. H.SO,Aq is oxidised to H.SO,Aq by oxygen, the halogens, and many other oxidisers.—8. Heated with phosphorus in a closed tube to 200°, H.S is produced (Oppenheim, Bl. [2] 1, 163).—9. Reduced by sinc and dilute sulphuric acid to H.S (v. Reinsch, D. P. J. 168, 286; 181, 382); with sinc alone, H.SO,Aq is partly reduced, probably giving H.S.O,Aq (v. Hyrosulphuroos ACID, p. 627).—10. Many metals which evolve H from H.SO,Aq or HClAq react with H.SO,Aq to form sulphites and sulphides, with evolution of little or no H (v. Federoff, Chem. Zeitung, 5, 16). For a fairly full qualitative examination of the interaction of Al, Cd, Mg, Ni, and Zn with H.SO,Aq, w. Schweitzer (C. N. 23, 293).—11. Many of the oxyacids of the halogens are reduced to hydracids by H.SO,Aq and H.S.; then S, and thionic acids (Wöhler, A. 89, 252; Maquenne, Chem. Zeitung.

1890 [1] 511).—18. Phosphoretted hydrogen produces H₂PO₄Aq, and S (Cavazzi, G. 16, 169).
14. Hydrogen sulphids passed into H₂SO₄Aq forms a solution containing H₂SO₄, H₂S₂O₆, H₂S₂O₆, probably H₂S₂O₆, S in suspension, and a colloidal form of S in solution; if the passage of H.S is continued until reaction ceases the final products are S and H,O (Debus, C. J. 53, 282; cf. Thionic acids, p. 698).—15. Many metallic salts are reduced, in aqueous solutions, by H2SO3Aq; salts of Ag and Hg to the metals, ferric to ferrous salts, &c. According to Divers a. Shimidzu (C. J. 49, 575), the reduction does not consist in the withdrawal of O by H₂SO₃Aq and the oxidation of that acid thereby to H₂SO₄Aq. The first step is looked on by D. a. S. as probably the formation of a sulphite of the metal of the salt, and this is followed by either the decomposition of this sulphite by water to metal and H₂SO₄Aq, or the reaction of the sulphite with some of the original, unthe surprise with some of the original, anchanged, salt to form metal and a persulphite (or -ic sulphite) of the metal.—16. With polassium thiosulphate H₂SO₂Aq forms K tri- tetra- and penta-thionates, and S (Debus, C. J. 53, 343).—12. ISSO As 2 includes when trackly and are 17. H₂SO₂Aq dissolves many freshly ppd. metallic sulphides, e.g. MnS, FeS, ZnS, forming thiosulphates (Schönbein, P. 104, 300; Heldt, J. pr. 83, 20).-18. Alkali nitrites give salts of nitrilosulphonic acid N(SO₂.OH)₃ (q. v., p. 601), and also salts of oxy-imidosulphonic acid and also state of oxy-inmostiphome acid N(OH)(SO_{...}OH)_{...} (q. v., p. 602). Using a dilute, ice-cold solution of H₂SO₄ (=5 p.c. SO₂), and adding 40 g. KNO_{...} in 1,000 c.c. water to 3 litres of this H₂SO₂Aq, Raschig (A. 241, 234) obtained NH₂(SO₂.OK) (cf. SULPHAMIC ACID, p. 567). Under certain conditions of concentration and temperature NO and N₂O, also NH₂ and sometimes NH₂OH, are produced. With nitrous acid the final products are NH₃, NO, N₂O, and H₂SO,Aq; according to Raschig (l.c.), NH₂(SO₂OH) is always formed, and the gaseous products are to be looked on as resulting from secondary reactions between nitrous acid and NH2(SO2OH) or other nitrogenised sulphonic acids formed in the primary reaction between the nitrous and sulphurous acids. With silver and mercurous nitrites Divers a. Haga (C. J. 51, 659) found that sulphites were produced, along with some NO and H₂SO₄, and more or less NH₂OH.— 19. For the reaction of H.SO, Aq with potassium platinochloride v. Platino-sulphonates, this vol.. p. 285.

Neither the amide SO(NH₂)₂ (v. the heading Thionamide), nor the imide SO.NH, of H₂SO₂ has been isolated; and it is doubtful whether the acid SO.OH.NH₂ or SO₂.NH₂.H is known v. Thionamic acid.

Constitution of sulphurous acid. The fact that many haloid derivatives of hydrocarbons interact with NaHSO, to form sulphonic acids—e.g. EtI+NaHSO,=EtSO,H+NaI—makesit probable that the Na in NaHSO, is in direct union with the S, because the S in sulphonic acids is almost certainly in direct union with the hydrocarbon radicle; hence it is likely that one H atom in H,SO, is directly combined with the S atom, and hence the formula for H,SO, is probably H,SO,OH. This view of the constitution of H,SO, is insisted on, and illustrated, by Divers (C. J. 47, 205).

Hydrates of sulphurous acid. Colourless, ice-like crystals are obtained by passing SO, into water surrounded by ice, by cooling saturated SO,Aq, or by passing moist SO, through a tube kept at a low temperature. After filtering quickly in a covered filter, and pressing between ditter paper at 8°, the crystals have the composition H.SO, xH₂O; Dopping (Petersburg Acad. Bull., 7, 100) found x = 10, Pierre (A. Ch. [3] 23, 416) found x = 8, Schönfeld (A. 95, 22) found x = 14, Roozeboom (R. T. C. 3, 29, 59, 75, 84: 4, 65) found x = 6, and this was confirmed by Geuther (A. 224, 218). Roozeboom (l.c.) gives S.G. of the crystals as 1.21 (referred to water at 4°); Geuther (l.c.) gives 1.147 as the S.G. after melting at 14°, and 14° as the m.p. with separation of some liquid SO, under the layer of SO, Aq. R. (l.c.) gives the following dissociation-pressures, which are independent of the quantity of the hydrate: 303 mm. at 0°, 754 mm. at 7.05°, 1177 mm. at 10°, 1773 mm. at 12·1°. According to R. the critical temperature of decomposition is 7.1° in an open vessel and 12.1° in a closed vessel.

HYPOSULPHUROUS H.S.O.Aq. ACID This acid has not been isolated. An aqueous solution is probably formed by decomposing the Na salt by dilute H.SO.Aq or H.C.O.Aq, and also perhaps by digesting H.SO.Aq with zinc clippings till the liquid is brownish red; but neither the aqueous solution of the acid, nor any of its calts, has been obtained free from impurities. For preparation of the sodium salt, and for references, v. Hyposulphites (p. 592). M. M. P. M.

Crystals (containing 2aq), sl. sol. cold water.
Reduces Fehling's solution in the cold. FeCl. gives a deep violet colour.—Salts: MgA' .-

ZnA'2: minute needles.-HA'HCl.-HA'HBr.-HA'HNO, aq: needles, sl. sol. water. SULPHYDRO-ACETIC ACID v. THIOGLY-

COLLIC ACID.

SULPHYDRO-ACETONE CH., CO.CH., SH.

Ethul derivative EtS.CH, Ac. Ethyl derivative EtS.CH,Ac. (171°). Formed from chloro-acetone and NaSEt (Autencieth, B. 24, 165). Yields a phenyl hydrazide [57].

[360] Phenyl derivative Phs.CH.Ac. [36°]. (266°). Formed from CH.CO.CH.Cl and NasPh in alcohol in the cold. Crystals. Yields a phenyl-hydrazide [87] (A., cf. Delisle, A. 260, 250). Combines with KHSO, and NaHSO.

SULPHYDRO-ACETOPHENONE. Phenul derivative C_{1,}H₂SO, i.e. C₆H₃S.CH₂CO.O₆H₃. [53°]. Formed from ω -bromo-acetophenone and NaOPh (Delisle, B. 22, 309). Needles (from alcohol), v. sol. ether

and acetone. SULPHYDRO-ACETYL-PROPIONIC ETHER. Phenyl derivative C13H16SO, i.e. C.H.S.CH.CO.CH.CO.Et. (197° at 18

min.). Formed from bromo-acetyl-propionic ether and NaSPh (Delisle, B. 22, 309). SULPHYDRO-ALLYL-QUINAZOLINE. Di-

hydride C.H. CII.N.C.H., [91's]. Formed from w-oxy-tolyl-allyl-thio-urea and HClAq at 100° (Söderbaum a. Widman, B. 22, 1670). Needles, v. c. sol. alcohol and benzene.

Reference. - OXY SULPHYDRO-ALLYL QUINAZO

DISULPHYDRO-DI-ALLYL-TRIAZOLE

NH CS.N.C.H. Formed from allyl-thio-ures and HNO, (Hector, J. pr. [2] 44, 505). Oil. B',H.PtCl,: crystalline pp.
o-SULPHYDRO-BENZOIC ACID

C. H. (SH). CO.H. Thio-salicylic acid. Formed by reducing o-sulpho benzoic chloride with zinedust and H.SO. (Delisle, B. 22, 2206). Amorphous powder, sl. sol. hot water, v. sol. alcohol. Not volatile with steam. - AgA'.

Thio-amide C₄H₄(SH).CS.NH₂. Formed by heating o-oxy-benzamide with P₂S₅ (Spilker, B.

22, 2771). Minute dark-red crystals.

Phonyl derivative Collos. Collos. Formed from o-diazobenzoic acid, phenyl mercaptan, and NaOHAq at 50° (Graebe a. Schultess, A. 263, 4). Plates (from alcohol) or needles (from HOAc); sl. sol. water. - NH.A.

-KA': needles, v. sol. water. -EtA'. [151°].
m-Sulphydro-benzoic acid C,H,(SH).CO,H. "Nounpy de De La Caracter and Active and Hollag on C.H.(SO,Cl).COCl (Frerichs, B. 7, 793). Colourless plates, m. sol. water.—Bah', 2¹,aq.—HgA'.,—PbC.H.SO, 3aq.—Cu(OH)A'.—AgA'.

a.SULPHYDRO-BUTYRIC ACID

CHEt(SH).CO.II. Formed from a-bromo-butyric

acid and alcoholic KSH (Duvillier, Bl. [2] 80, 507). Sol. water, alcohol, and ether.

Sulphydro-isobutyric acid HS.CMe, CO.H. Formed from a-brome isobutyric ether by successive treatment with alcoholic K₂S and alcoholic KOH (Lovén, J. pr. [2] 33, 109). a-SULPHYDRO-CINNAMIC ACID

C.H..CH:C(SH).CO₂H. [119°]. Formed, together with sulphocyanic acid, by heating benzylidene-rhodanic acid C,H,:CH:C(SH).CO.S.CN with baryta-water (Ginsburg a. Bondzynski, B. 19, 128; M. 8, 350). Yellowish crystals. V. sol. alcohol, ether, benzene, and CS₂, nearly insol. water. By treatment with iodine in alcoholic solution it is oxidised to di-sulphido-di-cinnamic

acid S₂(C₂HPh.CO₂H)₂.

Reference.—NTRO-SULPHYDRO-CINNAMIC ACID.

BSULPHYDRO-CROTONIC ACID. Ethyl

derivative CH₃-C(SEt):CH.CO.H. [113°].

Formed from β-chloro-crotonic acid [94·5°], mercaptan, and Na (Autenrieth, A. 254, 235; B. 20, 3189). Crystals, insol. water, v. sol. ether and alcohol. Gives a dark-green colour on warming with isatin and H₂SO₄. Yields CH₃-C(SEt):CH₂ (110°) on heating above its melting-point.—

BaA'₂ aq.—AgA': silky needles, not decomposed by hot water. Ac₂O forms the compound CH₄-C(SEt):CH.CO.OAc, a brownish oil.

Isomeride of the ethyl derivative CH₊C(SEt):CH₊CO₊H. [92°]. S. (alcohol) 20. Formed in like manner from the isomeric β-chloro-crotonic acid (A.). Crystals, nearly insolwater. Forms a dark-green liquid on warming with isatin and H_sSO₊. Where heated alone it yields the same ethyl-sulphydro-propylene (110°) as its isomeride.—BaA'₂ aq: thin plates (from Aq).

as its isomeride.—BaA', aq: thin plates (from Aq).

Phenyl derivative v. Phenyl-sulphydroCROTONIC Agid.

SULPHYDRO-ETHYL ALCOHOL

HO.O.H.SH. Formed from glycolic chlorhydrin and alcoholic KSH (Carius, A. 124, 258). Oil, v. e. sol. alcohol. Oxidised by HNO₂ to isethionic acid.—Hg(O₂H₃OS)₂. Needles (from warm alcohol).

SULPHYDRO - ETHYL - QUINAZOLINE.

Dihyàride C.H. CH. NEt [103°]. Formed by warming \(\omega\)-tolyl-ethyl-thio-urea with HCl (Söderbaum a. Widman, B. 22, 2936). Needles.

B'HAUCI. [118°].—B'_HPtCl. [208°].

SULPHYDRO - METHANE DISULPHONIC

SULPHYDRO METHANE DISULPHONIC ACID HS.CH(SO.H), Formed by boiling the trisulphonic acid with HOAc (Albrecht, A. 161, 134). Gives a blue colour with FeCl₃.—K.A." ½ aq.—Pb₃(CHS₂O₆)₂ 8aq. Small needles.

-Pb₃(CHS₃O₆)₂ Saq. Small needles.
Sulphydro-methane trisulphonic acid

HS.C(SO.H). Formed by boiling CS₂ or CSCl, with K.SO.Aq.— K.A''' 2aq: triclinic crystals. S. 2 at 12°. Gives a blue colour with FeCl₂.— (NH.).A'' aq. Thin plates.

SULPHYDRO-METHENYL-AMIDO-CRESOL

[4 1/2] C₀H₃Me<0>C.SH. [217°]. Formed by
heating benzene-azo-p-cresol with CS₂ at 200°
(Jacobsen a. Schenke, B. 22, 3235). Needles.

SULPHYDRO - METHENYL, AMIDO - (a) - NAPHTHOL C₁₀H₂ N C.SH. [above 220°]. Formed by heating an alcoholic solution of S₂(C₁₀H₂,NH₂[1:2]), with CS₂ (Jacobson, B. 21, 2624). Needles. Oxidised by K₂FeCy, to a crystalline disulphide.

Sulphydro methenyl - amido - (β) - naphthol. [249°]. Formed by heating benzene-azo.(β)-naphthol with OS₂ at 250° (Jacobson, B. 21, 414). Needles, sl. sol. benzene. HClAq at 170° yields amido-(β)-naphthol. An alcoholio solution of iodine forms crystalline (C₁₀H₂CN)>C)₂S₂-

SULPHYDRO . METHENYL . α - AMIDO-WAPHTHYL MERCAPTAN $C_{10}H_{\bullet} < {N \atop S} > C.SH.$ [above 240°]. Formed by heating α -naphthyl

thiocarbimide with S at 225°, and got also by the action of CS₂ on di-amido-di-naphthyl disulphide (Jacobson, B. 21, 2625; 24, 1406). Minute rosettes, sol. alcohol. Oxidised by

 K_sFeCy_s to $(C_{10}H_s < N_S)_2S_2 - B'HgCl_2$. [210°].

Sulphydro - methenyl - amido - (\$\beta\$) - naphthyl mercaptan [232°]. Formed by heating (\$\beta\$)-naphthyl thiocarbimide with S. Minute needles, Yields a methyl ether [74°], crystallising in needles.

SULPHYDRO . METHENYL . o . AMIDO-PHENOL $C_0H_4 < \stackrel{N}{<} > C.SH$. Thiocarbamido .

phenol. [196°]. Formed by boiling an alcoholic solution of o-amido-phenol for several days with CS₂ in a current of H as long as H₄S is given off (Dünner, B. 9, 465). Formed also by heating oxy-phenyl-thio-urea, and by heating o-oxy-phenyl-allyl-thio-urea with HCl at 130° (Von Chelmicki, J. pr. [2] 42, 442; B. 20, 177). Obtained also by adding dilute alcohol to a mixture of potassium xanthogenate and amido-phenol hydrochloride (Kalckhoff, B, 16, 1825). Needles (from water), sl. sol. cold water. Sol. NH₃Aq, crystallising therefrom unaltered.

Reactions.—1. Converted in o-amido-phenol by HClAq at 170°, and by NH₂Aq at 200°.—

2. Ac₂O yields C₆H₄ $\stackrel{\sim}{O}$ C.SAc [120°].—3. BzCl forms benzenyl - amido - phenol and C₈H₄(NHBz).OBz.—4. An alcoholic solution of iodine, added to its solution in NaOHAq, forms (C₆H₄ $\stackrel{\sim}{O}$ C)₂S₂ [110°], which is reconverted by hot dilute NaOHAq into sulphydromethenyl-amido-phenol.—5. Boiling methylaniline forms a base (? C₈H₄ $\stackrel{\sim}{O}$ C.NPhMe)

which yields B'.H.,PtCla. Salt.—AgC,H.,NSO. Amorphous.

Salt.—AgĈ,H,NSÖ. Amorphous. Ethyl ether EtC,H,NSÖ. (c. 267°). Solid, melting below 35°; volatile with steam.

SULPHYDRO-METHENYL-AMIDO-PHENYL-MERCAPTAN $C_6H_4 < S > C.SH.$ [179°] (H.); [174°] (J. a. F.).

Fornation.—1. By digesting o-amido-phenol with CS₂ (Hofmann, B. 20, 1789).—2. By heating C₀H₅.N₂.C₀H₅ with CS₂ at 265° (Jacobson a. Frankenbacher, B. 24, 1403).—3. By heating phenyl thiocarbimide with sulphur.

Properties.—Needles or plates, v. sol. alcohol and ether. Forms B'HgCl₂. Oxidised by $K_2Cr_2O_7$ to $(C_0H_4 {\stackrel{N}{\le}} C)_2S_2$, which yields $B'K_2Cr_2O_7$

[180°]. MeI yields C₆H₄<\(\sigma\)\sigma\(\circ\)C.SMe [52°],
which forms B'₂H₂PtCl₈, crystallising in plates.
SULPHYDRO - METHENYL - BENZENYL -

THIO-AMIDOXIM $C_0H_3.C < N.S > C.SH.$ [162°]. Formed by the action of CS_2 on an alkaline alcoholic solution of benzenyl-amidoxim (Crayen, B. 24, 388). Needles, nearly insol. water and cold alcohol. Conc. HClAq at 150° decomposes it into benzoic acid, CO_2 , NH_3 , H_2S , and S. NaOEt and EtI yield $C_2H_3.C < N.S > CEt$ [49°].

while benzyl chloride forms, in like manner, C.H.O.N.S.O.CH.Ph [79°].

SULPHYDRO - METHENYL - p - TOLYL - METHENYL-THIO-AMIDOXIM C.H.sN.2S. i.e. C.H.Me.C NSSC.SH. [166°]. Formed from CS2 and tolyl-methenyl-amidoxim (Crayen, B. 24, 391). Crystals (from alcohol acidulated with HOAc), insol. water, sl. sol. ether. Forms salts with bases. p-Tolyl-methenyl-amidine forms the salt C₆H₄Me.C(NH₂):NHHA' [172]. Boiling EtI and NaOEt yield C_eH₁Mc.C \ll ^{N,S}_NC.SEt [37°].

SULPHYDRO - METHYL - GLYOXALINE

 $C_4H_6SN_2$ i.e. CH.NMe C.SH. [142°]. (c. 280°). Formed by boiling CH(OEt), CH₂NH₂ with methyl thiocarbimide, alcohol, and dilute (30) Plates, v. sol. water, sol. alcohol. B'₂PtCl₁.

B'AuCl₂.—C₄H₂AgSN₂.—B'McI. [148²]. Needles.

derivative CH.NMe CSMe. Methylimidazolyl methyl sulphide. (225° uncor.). Formed by treatment with MeI and alkalis. Liquid, miscible with water, alcohol, and ether. Boiling dilute HNO, forms C₃H₁(NO₂)SN₂ (85°), which yields B'₂H₂PtCl₄ [197°). C₃H₂SN₂MeI. [173°]. Needles, v. sol. Aq.

Reference. - OXY-SULPHYDRO-DI-METHYL-GLY-

SULPHYDRO-DI-METHYL-PYRIDINE

CS CH: CMe NH. [210°-215°]. Formed by heating oxy-di-methyl-pyridine with P.S. at about 160° (Guthzeit a. Epstein, B. 20, 2113). Needles, v. sol. hot water and alcohol.

SULPHYDRO - METHYL - QUINAZOLINE. Dihydride C,H, CH, NMe

Formed by warming ω -oxy-tolyl-methyl-thiourea with HClAq (Söderbaum a. Widman, B. 22, 2935). Needles.—B',H,PtCl, [195°].—B'HAuCl, [153°]. Minute needles.

SULPHYDRO-METHYL-QUINOLINE

 $C_{io}H_{o}NS$ i.e. $C_{o}H_{o} < C_{N}E:CH$ [253°]. Formed by heating (Py. 3, 1)-oxy-methyl-quinoline with P_2S_3 (Roos, B. 21, 625). Small brown needles (from alcohol). Tastes bitter. Insol. cold water. Does not react with hydroxylamine and phenylhydrazine. H₂O₂ forms C₂₀H₁₀N₂S₂ [167°] crystallising from benzene in plates. EtI and alcohol at 100° form C₆H₄ CMe:CH₁ N=C.SE₁, which is oily and yields B'HI [240°] and B'2H2PtCl 14aq crystallising in reddish prisms.

Salphydro-methyl-quinoline C.H. C(SH):CH [187°]. Got by heating (Py. 1,8)-oxy-methyl-quinoline with P₂S₄ at 150° (Roos, B. 21, 629). Yellow prisms (from water). Eti and NaOEt yield C₁dH, EtNS [56°].—B'HCl. [205°-210°] (Conrad a. Limpach, B. 21, 1972). SULPHYDRO.METHYL.THIAZOLE.

hydride CH₂—N>C.SH. [82°]. Formed from 8-bromo-propyl-amine hydrobromide, NaOHAq, and CM, (Hirsch, B. 28, 968). White needles, v. sol. hot water. Yields C.H. MeNS(SMe)

(217°), C.H.,MeNS(SEt) (229°), and the propyl ether C.H.,MeNS(SC.H.) (247°).

ψ-SULPHYDRO-(a)-NAPHTHYL-METHYLBIAZOLE O CMe:N
CS-NC₁₆H. [86°]. Formed

from acetyl (a)-naphthyl-hydrazine and CSCl2 in CHCl, (Preund, B. 24, 4184). Yellow needles, v. e. sol. alcohol. The isomeride from (3). naphthyl-hydrazine melts at 109°.

SULPHYDRO-PENTHIAZOLE. Dihydrids $CH_2 < \stackrel{CH_2.S}{CH_2.N} > C.SH.$ [132°]. Formed by shaking γ-bromo-ethylamine hydrobromide with NaOHAq 7-Diomo-Ediplantine yardololinic with radio and CS₂ in the cold (Gabriel a. Lauer, B. 23, 92). Crystals, v. sol. hot water and alcohol, insol. acids, sol. NaOHAq. Bromine-water at 100° produces CH₂(NH₂).CH₂.CO₂H.

ψ - SULPHYDRO - PHENYL - AMIDO - (α)

NAPHTHYL-THIOBIAZOLE C18H12N3S2 i.e. SC(NHPh):N . [255°]. Formed by mixing NHPh.CS.NH.NHC₁₆H, with CSCl₂ in benzene (Preund, B. 24, 4192). Colourless crystals, v. sol. acetone, sl. sol. alcohol.

ψ - SULPHYDRO - PHENYL - MENHYL - BI -AZOLE OCS. NPh. [72°]. Formed from dichloro-phenyl-methyl-biazole dihydride and alcoholic ammonium sulphide (Freund a. Kuh, B. 23, 2837). Formed also from NHAc.NHPh and CSCl. (Freund a. Goldschmidt, B. 21, 2456). Prisms (from alcohol). Yields phenyl thio-carbimide on distilling with P₂S₂. SULPHYDRO-PHENYL-GLYOXALINE

C₉H₈N₂S i.e. CH:CH NPh. [181°]. Formed boiling NHPh.CS.NH.CH2.CH(OEt)2 with dilute H.SO. (Wohl a. Marckwald, B. 22, 569, 1353). Needles (from hot water), v. sol. B'2H2PtCl.: deep-red crystals.—B'MeI. [152°].

Methyl derivative N=C(SMe) NPh. [54°]. Formed by treatment with alcoholic NaOH and MeI. White needles (from alcohol), insol. water.—B'C,H,N,O,.—B'HNO,. Needles, v. c. sol. water.—B'MeI. [177°]. Crystalline rosettes (from water). Oxidised by dilute HNO, to a nitro- compound (116°).

ψ - SULPHYDRO - PHENYL - DI - METHYL-

PYRIDINE DICARBOXYLIC ETHER

CMe:C(CO_Et) NPh. [245°]. Formed by heating CS CMe:C(CO_Et) O with aniline control of the contro and HOAc (Guthzeit a. Epstein, B. 20, 2112). Sulphur-yellow crystals (from alcohol).

. SÚLPHYDŘO - PHENYL - NAPHTHYL -BIAZOLE O CS . NC 10H7. [164°]. Formed from NHBz.NHC, H, and CSCl, in CHCl, (Preund, B. 24, 4186). Needles, v. sol. alcohol. SULPHYDRO - PHENYL - QUINAZOLIME.

Dihydride C.H. CH., NPh. [1970]. Formed by warming ω-oxy-tolyl-phenyl-thio-urea with conc. HClAq (Söderbaum a. Widman, B. 22, Needles. - B',H,PtCl, [219°]. -1671). B'HAuCl. [197°]. Needles.

Reference.—Oxy - SULPHYDBO - PHENYL - QUIM-

DI-SULPHYDRO-DI-PHENYL-THIO-UREA. Di-mathyl derivative CS(NH.C.H.SMe)2. [162°]. Formed by boiling [1:2] NH2.C.H4.SMe with CS₂ and solid KOH (Hofmann, B. 20, 1794). Prisms, v. sl. sol. alcohol. Forms, when heated, SCN.C.H.SMe (c. 270°).

B-SULPHYDRO-PROPIONIC ACID

CH₂(SH).CH₂.CO₂H. Formed from β-iodopropionic acid and KSH. Got also by reducing sulphido-dipropionio acid (Lovén, J. pr. [2] 29, 376). Liquid, miscible with water, alcohol, and ether. Easily oxidised by air. CuSO, gives a pale-violet pp., but if not in excess it forms a yellow pp. of CH₂(SCu).CH₂.CO₂H while S(C₂H₄.CO₂H)₂ remains dissolved. -Hg(S.C2H1,CO2H)2. Scales.

-Bi(S.C₂H₄.CO₂H)₃.

Isomeride. - Thiomactic acid.

SULPHYDRO - PROPYL - PHTHALIMIDE C.H.O.:N.OH., CH., CH., SH. [48°]. Formed by beating \(\gamma\)-bromo-propyl-phthalimide with KSHAq at 100° (Gabriel a. Inter, B. 23, 88). Needles (from hot ligroin). Fuming HClAq at 180° forms phthalic acid and γ-amido-propyl mercantan.

(Py. 3)-SULPHYDRO-QUINOLINE

C.H. CH:CH N:C.SH [174°]. Formed by heating (Py. 3)-oxy-quinoline with P₂S, at 140° (Roos, B. 21, 620). Yellow plates (from dilute alcohol), insol. cold water, sol. acids and alkalis. Oxidised by H.O. to C., H., N., S. [137]. Eti and alcohol at 100° 3 rm C., H. (SEt) NHI [154°], which yields (C., H. (SEt) N)_H. PtCl. aq, melting, when anhydrous, at 190°

SULPHYDRO - THIAZOLE. Dihydride CH_rS CH_rN>C.SH. [107°]. Formed from bromoethyl-amine, NaOH, CS2, and alcohol (Gabriel, B. 22, 1152). Needles, sol. alcohol and hot water. Sol. alkalis. Bromine-water yields Alcohol, KOH and MeI form oily taurine. $C_2H_4 < S > C.SMe$ (217°), insol. alkalis but sol.

Reference. - OXY-SULPHYDRO-THIAZOLE.

SULPHYDRO-ACETONE. The compound CH, C(SEt), CH, SEt (170°) is formed by passing gaseous HCl into CH, CO, CH, SEt mixed with mercaptan (Autenrieth, B. 24, 167).

w-SULPHYDRO-o-TOLUIC ACID. Methyl ringting CH.(SMe).CaH..CO2H. [138°]. derivative CH₂(SMe),C₆H₁,CO₂H. [138⁵]. Formed by the action of conc. HClAq at 100° on the nitrile CH₂(SMe),C₆H₄CN (278⁵), which is got by dissolving thio phthalimidine in alcoholic KOH and adding Me¹ (Day a. Gabriel, B. 23, 2484). Light oil.

SULPHYDRO-ISOVALERIC ACID

CHPr(SH).CO.H. Formed from a-bromo-isovaleric acid and alcoholic KSH (Duvillier, Bl. [2] 80, 507).

SUPER. Use of this prefix applied to inor-ganic compounds. The prefix super is sometimes employed to denote the presence in compounds of relatively more of the characteristic negative element, or elements, than is found in the normal compounds of the same form. The prefix per is, however, much oftener used than super. It has been proposed by Mendeléeff to designate the oxides that belong to the same type as H.O.

superoxides, to distinguish them from other peroxides (v. Oxides, vol. iii. p. 660).

M. M. P. M. SUPERBIN. A poisonous substance contained in the root of Gloriosa superba (Warden, Ph. [3] 11, 495).

SYCOCERYL ALCOHOL C.H.O. Occurs as acetyl derivative in the resin of Ficus rubiginosa (De la Rue a. Müller, C. J. 5, 62; Rennie a. Goyder, C. J. 61, 916). Thin crystals (from alcohol), insol. water and alkalis. BzCl yields a crystalline benzoyl derivative.

Acetyl derivative C34H36O2. [121°]. Flat six-sided tablets, v. sol. hot alcohol, ether, and chloroform.

SYLVANE C.H.O. (63°). S.G. 887. Got by distilling pine-wood (Atterberg, B. 13, 879). Liquid, readily resinified. Oxidised by KMnO, to acetic acid. Not attacked by Na, alkalis, or Ac.O. HCl passed into its ethereal solution forms a small quantity of C15H22O, a liquid boiling at 240°

SYLVANE-ACETIC ACID v. METHYL-FUR-FURYL-ACETIC ACID.

SYLVANE - CARBOXY-ACETIC ACID METHYL-CARBOXY-FURFURYL-ACETIC ACID and ME-THRONIC ACID.

SYLVESTRENE v. TERPENES.

H=9.7 p.c. SYLVIC ACID C = 78.7 p.c. [c. 162°]. $[\alpha]_{D} = -53^{\circ}$. This acid is obtained from colophony by repeated crystallisation from dilute alcohol, and is perhaps identical with abietic acid (Liebermann, B. 17, 1884; Haller, B. 18, 2166). By heating with HI and P it is converted into a terpone $C_{10}H_{10}$. Sylvic acid appears also to be formed by the action of gaseous HCl on an othereal solution of dextropimaric acid (Vesterberg, B. 19, 2173). A sylvic acid C₂₀H₂₀O₂ is described by Maly (Sitz. W. 44, 121) as formed by adding dilute H₂SO₄ or gaseous HCl to a solution of abietic acid. Duvernoy (A. 148, 147) obtained a sylvic acid [129°] by distilling pimaric acid in vacuo.

Isosylvic anhydride C40H58O3. 30 mm.). $a_p = +63^\circ$. Got by distilling rosin in vacuo (Bischoff, B. 23, 1921). Colourless, brittle, microcrystalline substance, insol. water, v. sol. alcohol and ether. Isosylvic acid [62°] is ppd. on adding dilute HOAc to its solution in

potash. SYLVINOLIC ACID C₂₅H₃₆O₄? [130°]. Formed, together with sylvic acid, by saturating an alcoholic solution of abietic acid with HCl (Maly, Sitz. W. [2] 44, 121). Amorphous powder, y. sol. alcohol and ether.—CaA".—Ag₂A": pulverulent pp., insol. NH,Aq.

SYMBOLS. Symbols are employed to ex-

press the composition, and, as far as possible, the interactions, of compounds; v. Equations,

the interactions, or compounds; v. Equations, CHEMICAL (vol. ii. p. 433), FORMULE (vol. ii. p. 572), ISOMERISM (vol. iii. p. 79), and cf. OFTICAL METHODS (this vol. p. 253). M. M. P. M. SYNANTHRENE C_{1.}H_{1e}. Phosene. Occurs in crude anthracene (Zeidler, A. 191, 298; cf. Barbier, A. Ch. [5] /, 526). Yellowish-white plates. Yields a di-bromo-derivative C_{1.}H₂Br₁ (1752) argetallising in minute yellow needles. [175°], crystallising in minute yellow needles, sol. alcohol (difference from di-bromo-anthracene). Di-bromo-synanthrene is oxidised by CrO, and HOAc to a quinone (?) [240°-250°].

SYNTHESIS. The building up of compounds from their elements, or from groups of elements.

SYNTONIN v. PROTEIDS.

SYNTONIN v. PROTEIDS.

SYRINGIN C₁,H₂O₂, [191^o]. Dimethoxyconiferin. Occurs in the bark of the lilia (Syringa vulgaris) and of the privet (Ligastrum vulgare) (Bernays, J. pr. 25, 121; Kromayer, Ar. Ph. [2] 108, 7; 109, 18, 216; 113, 19; Kroner, G. 18, 215). White needles (containing aq), v. sl. sol. cold water, v. sol. alcohol, insol. ether. Its aqueous solution is slightly bitter, is laworotatory, and does not ppt. metallic salts. Conc. HNO₂ gives a blood-red solution. Conc. HClAq forms a colourless solution, turning blue, and finally giving a blue pp. Conc. II₂SO, gives a yellowish green colour, changing to violethrown and, on pouring into water, giving a bright-blue solution, which soon deposits an azure powder. Does not reduce Fehling's solution. Decomposed by emulsin into glucose and syringenin. KMnO₄ yields glucosyringic acid. CrO₂ forms glucosyringic aldehyde.

Syringenin C, H, O, i.e. [5:3:4:1]? C,H,(OMe),(OH).C,H,OH. Formed as above. Resembles coniferyl alcohol. Glucosyringis acid $\mathbf{C}_{li}\mathbf{H}_{si}\mathbf{O}_{ls}$. [208°]. Formed as above. Needles or prisms (containing 2aq), sl. sol. cold water. Decomposed by dilute $\mathbf{H}_s\mathbf{SO}_s$ into syringic acid and glucose.

Syringic acid C.H.(OH)(OMe), CO.H. Dimethyl derivative of gallic acid. [202°]. Decomposes at 230° into Co, and the di-methyl derivative of pyrogallol.—BaA', 3aq: four-sided tables.—McA'aq. [83-5°]. Crystals, sol. Aq.

Methyl derivative C_nH₁(OMe), CO₁H₂ [168°]. Needles. Yields C_nH₂(OMe), when distilled with lime. Identical with the tri-methyl derivative of gullic acid.—MeA'. [82·5°]. Needles. Glycosyringic aldehyde C₁₃H₂₀O₂. [162°]. Colourless, silky needles. Decomposed by emulsin or dilute H₂SO₄ into glucose and syringic aldehyde. Yields a phenyl-hydrazide [156°] and a crystalline oxim.

Syringic aldehyde C_uH₁₀O₄ i.e. C_uH₁(OH)(OMe)_CHO. [111·5°]. Small needles, smell²..g like vanillin. Turns brown in air. Reacts with phenyl-hydrazine, and combines with NaHSO₄.

Ŧ

TAIGUIC ACID v. LAPACHIC ACID.

TALOMUCIC ACID $C_cH_{10}O_a$. [158°]. [a]_D = +29·4° at 20°. Formed from talonic acid and HNO₃ (S.G. 1·15) (Fischer, B. 24, 3625). Minute plates, v. e. sol. cold water and warm alcohol; v. sl. sol. ether. Converted by HCl and HBr at 150° into dehydromucic acid. Yields a phenyl-hydrazide [185°-190°]. Pyridine at 150° forms mucic acid.—CaA": crystalline powder.

TALONIC ACID C₄H_{1,O}. Formed by heating galactonic acid with pyridine at 150° (Fischer, E. 24, 3622). Purified by means of its brucine salt. Syrup, very soluble hot alcohol. Levorotatory. Yields a phenyl-hydrazide C₄H_{1,O4}(N,H₂Ph) [c. 155°].—CaA', aq. Needles (from alcohol), v. e. sol. water.—Brucine salt. [130°-133°]. Crystals, v. sol. water.

TAMPICIN C₃,H₃,O₁, [130°]. A neutral substance resembling convolvulin, occurring in Tampica Jalan (Spirgatis, N. R. P. 19, 452). Resin, v. sol. alcohol and ether. Converted by hot baryta-water into amorphous tampicic acid C₃,H₉₀O₁, Boiling dilute acids resolve tampicin into glucose (3 mols.) and tampicolic acid C_{1e}H₃₂O₅, which crystallises from dilute alcohol in minute needles and forms NaA' and EtA', both being crystalline.

TANACETIN $G_{11}H_{16}O_{4}$. A bitter substance obtained from the leaves and flowers of the tansy (*Tanacetum vulgare*) (Leroy, *J. Chim. Med.* 21, 357; Leppig, *J.* 1882, 1175). Amorphous, sol. water and algohol.

TANACETOGENIC ACID C₃H₁₄O₂. (114° at 15 mm.). Formed by the action of Br and (4 p.c.) NaOHAq on tanacetone (Semmler, B. 25, 3346). Oil, solidified below 0°.—AgA'.

TANACETONE $C_{10}H_{16}O$. (84.5° at 13 mm.). Occurs in oil of absinthe, thuja, and sage, con-

stituting the chief part of absinthol, salviol, and (\$\beta\$)-thujol (Semmler, \$B. 25, 3843, 3850). Got from ethereal oil of Tanacetum vulgare by shating with NaHSO₃, decomposing the crystalline product with Na₂CO₃, and distilling with steam. Oil, v. sol. alcohol and ether. Poos not reduce armoniacal AgNO₃. Dextrorotatory; \$a = 38\frac{1}{2}^{\text{a}}\$ in a 20 c.m. tube. S.G. \$\frac{2}{2}\$ 913. \$\mu_{D} = 1.450\$. Reactions.—1. Br and KOHAq yield bromo-

Reactions.—1. Br and KOHAq yield bromoform, hence it probably contains CO.OH,—2. Reduced in alcoholic solution by Na to tanacetyl alcohol C₁₀H₁₀O, (93° at 13 mm.), S.G. 2° '925, µ₀= 1·4635. This body does not combine with Br. With PCl, it yields tanacetyl chloride (72° at 10 mm.).—3. Oxidised by KMnO, to Tanacetketo carboxylic acid C₁₀H₁₀O, Needles (78°) (from ligroin) or plates [74·5°] (from water). Yields AgA'. Hydroxylamine yields C₁₀H₁₀O, (NOII) [103] when prepared from the needles and [169°] when got from the plates. The ketonic acid is oxidised by Br and NaOH to tanacetogen dicarboxylic acid C,H₁₀O, (142°3). Plates (from water). This acid yields Ag,A" while Ao,O yields the anhydride C,H₁₀O, [55°], which gives jsopropyl succinic acid [114°] when fused with potash.

Neduced in alcoholic solution by Na to tanacetyla mine C₁₀H_{1,8}:NOH. [52°]. (186° at 20 mm.). Reduced in alcoholic solution by Na to tanacetyla mine C₁₀H_{1,1}NH₂ (80·5 at 14 mm.), S.G. ²²·874, μ₀ 1·462, which yields B'HCl, which when heated gives tanacetene C₁H_{1,8} (63° at 14 mm.), S.G. ²²·841, μ₀ 1·476. Tanacetone oxim may be converted by warming with alcohol and dilute sulphuric acid into the cymidine C₈H₄(C₈H₁)(NH₂)Me [1:3:4], whence nitrous acid forms carvacrol.

TANACETOPHORONE $C_1H_{12}O$. (90° at 18 mm.). S.G. 22° 938. μ_D 1'482. Got by distilling tanacetogen dicarboxylic soid with soda-lime

(Semmler, B. 25, 3350). An oil, smelling like samphor-phorone. Reacts with hydroxyl-amine.

TANGHININ C₂₇H₄₀O₂2aq. [182°]. [a]₂₀ — 67°. Obtained from the kernels of Tanghinia venenifera of Madagascar (Arnaud, C. B. 108, 1255; 109, 70!). Crystals (from alcohol), v. sl. sol. water, sl. sol. ether. Cardiac poison. Resinified by dilute acids. Barytawater at 180° forms C₂₇H₁₁O₁₀.

TANNIN. TANNIO ACIDS. Under the

Under the above names are included a large series of compounds, occurring in the vegetable kingdom, of different constitutions, many of which have been very imperfectly studied. Their chief characteristics are their astringent taste and property of giving a dark-blue or green colouration with iron salts and a precipitate with a solution of gelatin. They all reduce solutions of the noble metals, and absorb oxygen in presence of alkalis. They are all aromatic derivatives, and yield on fusion with potash either pyrogallol or pyrocatechin. In some cases they have been synthetically prepared from these phonols and their derivatives, but in many cases the tannin appears to exist in the plant as a glucoside and attempts at a synthetical production have proved futile. Schiff. (B. 15, 2590) prepared some of the tannins synthetically, and concluded that they were anhydro- compounds of gallic and protocatechuic acids respectively. Etti (A. 186, 332) and others have also, for example, synthetically prepared catechutannic acid by heating pyrosatechin with water or alkalis. Gallotannic acid was formerly believed to be a glucoside, but subsequent investigation showed that the amount of sugar present was variable, and Schiff (A. 170, 43) finally proved that, although existing in the plant as a very unstable glucoside, when it was isolated it had the constitution of an anhydro- acid formed by the removal of one molecule of water from two molecules of a trioxy-benzoic acid. He considered that in gallotannic acid the anhydride was formed thus :-C,H2(OH)3CO.O.C,H2(OH)2COOH, whilst C. Etti, who has similarly investigated the tannins of the formulæ $C_{12}H_{18}O_{20}$ and $C_{20}H_{20}O_{20}$ has proved that they also are not glucosides, and regards them as derivatives of a ketonic acid of the formula $C_0H_2(OH)_3.CO.C_0H(OH)_3.COOH$. It would appear, then, possible to define the tannic acids as mono-carboxyl acids formed by condensation from two molecules of poly-oxy-benzoic acids and which exist as unstable glucosides in plants. The ease with which gallotannic acid is hydrolysed renders it probable that the difference in constitution between Schiff's and Etti's formulæ does actually exist, and renders it possible to subdivide the tannins into these two groups so soon as the different tannins have been re-examined from this point of view. ketonic character of the tannins was established by Etti through noting that they reacted with phenyl-hydrazine and hydroxylamine.

The origin of tannin in plants has given rise to much debate. According to Waage (Ph. 1890; Phar. Centr. 1891, 247) its formation is similar to that of the conversion of glucose into starch. The plant removes one molecule H.O from glucose for reserve purposes, and it under favourable circumstances three molecules H.O can be removed, a body having the composition

of a triketohexamethylene would be produced

CH₂COCH₂COCH₂CO. This constitution corresponds to the secondary form of phloroglucin. It is probable that the phloroglucin combines with the CO₂ in the nascent state produced by the respiration of the plant, and is thus converted into a carboxylic acid (gallic acid); two molecules of this acid by the removal of another molecule of water would then form tannin. Light and chlorophyll are necessary for the production of tannin.

Westermaier (B. B. 1887, 127-143) showed that with experiments made with Quercus pedunculata the tannin migrates downwards through the bark and the pith. Starch is always present, and it is probable that the starch only migrates in the form of tannin. The leaves of Rumex patentia and Rheum rhaponticum give both the starch and the tannin reactions. Schultze (A. a. 14, 525-526; B. C. 18, 137), by microchemical observations, also supports the view of Sachs and Heberland that the leaves of evergreens contain tannin as a winter reserve material. Tannin and starch only rarely occur When the simultaneously in the same cells. cells are rich in starch they contain a smaller amount of tannin, and vice versa.

In the case of leaves containing fatty oils and tannin, the cells which contain the oil are free from tannin, and cells containing no oil are free from starch. Kraus (B. C. 330-334) also notes that the formation of tannin in leaves depends on the presence of light and CO2, but believes that it acts more as a protecting agent either to prevent the plant from being eaten or rotting than as a reserve material. He points out that as fallen leaves contain as much tannin as they did during their best time of growth, the leaf tannin is of no value to the plant. Heckel a. Schlagdenhauffen (Ph. July 1892) note that the protecting leaf buds of certain species of gardenia contain a resinous substance which on analysis gives figures resembling cinchotannic acid. Both the gardenias and the cinchonas belong to the same order of plants (cf. Cross a. Bevan, C. J. 41, 106; Gardiner, Ph. [3] 14, 588; Braemer, Les Tannoïdes, Toulouse, 1890; Büsgen, C. C. 1890, 397).

Classification.—No satisfactory classification of these bodies exists. Wagner (Fr. 5, 1) divides them into pathological and physiological tannins. The former are chiefly glucosides, and precipitate gelatin, yield gallic acid when hydrolysed with dense sulphuric acid, and when heated alone form pyrogallol. The physiological tannins, on the other hand, form leather, and on distillation yield pyrocatechin. The old classification into iron-blueing and iron-greening tannins is found now to be untenable, as the presence of acids and salts modifies the colour which the tannins produce with FeCl₂, and the purity of many of the tannins examined by the earlier investigators cannot be guaranteed.

gators cannot be guaranteed.

Reactions.—The oxidation of gallic and tannin acids by nitric acid of moderate dilution yields oxalic acid and two acids, probably tricxy-glutaric and trioxy-butyric. The acetyl oquercitannic acid yields the same acids on oxidation (Böttinger, A. 257, 248-252). Metallic Nadoes not reduce gallic acid in absolute alcohol,

but tannic acid similarly treated undergoes simple hydrolysis, the yield of gallic acid amounting to 60 p.c. of the weight of tannin. No reduction products could be prepared (Bottinger, A. 258, 252-260). Ammonia and zinc-dust at 60° convert both acids into benzoic acid. Dilute H₂SO₄ and Zn also form benzoic from gallic acid (Guignet, C. R. 113, 200-201).

The action of heat. Most tannins begin to blacken at 120°, and at 160° decomposition into metagallic acid, and either pyrogallol or pyrocatechin, takes place. Those which yield pyrogallol usually also form a 'bloom' on leather, and give a blue colour with FeCl₂. This class includes galls, sumac, chestnut, and oak bark. The pyrocatechin-yielding tannins do not form a 'bloom' on leather, give green compounds with FeCl, and include hemlock, catechu, rhatany, and mangrove (Trimble, The Tannins, 1892).

The products of the action of heat on the tannins are best obtained by allowing the heating to take place on the material suspended in glycerin (1 g. in 5 c.c. glycerin). After heating to 200° for 80 minutes, dilute with water, and extract with ether. The ethereal extract contains either pyrogallol or pyrocatechin. The tannin must be freed from gallic acid and catechin before subjecting it to this test by previous ether

extraction of the aqueous solution.

The action of dilute acids. 2 p.c. absolute HCl at 100° in sealed tubes decomposes the tannios; insoluble ellagic acid, anhydrides, or phlobaphenes separate, and the filtrate contains gallic acid, glucosc, and unaltered tannin. Glucose should be removed from the tannin by repeated lead acetate precipitation before this treatment, or the amount of glucose before and

atter hydrolysis may be determined by Fehling's solution (Wehmer a. Tollens, A. 213, 327).

The action of alkalis. The pyrocatechinyielding tannins on heating with alkali yield protocatechuic acid, and either phloroglucin or acetic acid. The pyrogallol-yielding tannins form gallic and ellagic acids (20 g. with 150 c.c. of KHO solution, sp.gr. 1.2 for 3 hours are convenient quantities (Trimble, The Tannius).

The tannins in the bark of oak chestnut, horsechestnut, fir, &c., are precipitated in brominated condition by bromine water; tannin, sumach tannin, and oak wood tannin are not so precipitated (Böttinger, A. 240, 330). oak tannin, Böttinger, by treating with acetic anhydride, has formed an acetyl-o-compound of the formula C_{1.}H₁Ac₂O₃, and from it two bromo-derivatives C_{1.}H₁BrAcO₃ and C_{1.}H₁Br₁AcO₃ (B. 20, 761-766). A benzoyl-o-derivative has also been obtained from tannin by treatment with conc. NaOHAq and benzoyl chloride (Böttinger, A. 254, 370). The same author has attempted A. 254, 370). to prepare cyanhydrins, but without success. Well-dried tannic acid heated with anhydrous HON in sealed tubes yielded only an amide of gallic acid. Treated with hydroxylamine no oxim was formed, but only gallic acid (4. 259, 182-136). With pure tannin phenyl-hydrazine, however, forms derivatives which do not however, forms derivatives which do not crystallise, CO₂ and N being evolved at the same time. The tannins experimented upon water extracts of sumach, divi divi, oak wood, oak bark and pine bark; the dry precipitates con-tained phenyl-hydrazine derivatives of tannic

and gallic acids, osazones of dextrose and lavulose, and caramel (A. 259, 125-132; A. 256, 342).

Tannin solutions are very unstable, undergoing hydrolysis into gallic acid on standing. The hydrolysis into gallic acid is almost quantitative when the acid is dissolved in conc. H.SO. and then water added (Böttinger, A. 254, 878). When heated with KHSO, and glycerin to 119°-200° and the melt extracted with water, a residue is left soluble in absolute alcohol which contains two new acids of the composition C₁₄H₁₄O₇Aq and called hydrotannic and isotannic soids respectively. The former, which is the less soluble in alcohol, forms with Ac₂O a tetra-acetyl-compound while the iso-acid forms a brown tri-acetyl-compound (C. J. 1892, 181).

Preparation of tannic acid for pharmaceu-tical purposes. Pelouze in 1834 first suggested the extraction of tannic acid from galls by per-colation with ether, and this method is still in use. The pardered galls are placed in a closed percolator with commercial ether containing alcohol and water. The ethereal layer contains gallic and ellagic acids, together with resins and fats and a small portion of the tampic acid; the lower aqueous solution contains nearly pure tannic acid. The percolation is stopped when the lower layer ceases to increase in volume. The B. P. method consists in taking the damp galls, macerating with commercial ether, and expressing through muslin (Leconnet a Dominé). The purest acid is obtained when 10 pts. powdered galls are allowed to stand two days covered in a percolator with a mixture of 12 pts. ether and 3 pts. alcohol. At the end of this time the percolation is commenced until 10 pts. are obtained. One-third its volume of vater is then added, and the mixture well agitated. The aqueous layer contains nearly pure tannic acid, and is evaporated rapidly in vacuo. The commercial acid is known under the names of ether-tannin, alcohol-tannin, or water-tannin, according to the method of extraction adopted on a large scale.

Purification.—Petroleum ether percolation removes fat, wax, and some of the colouring matter. Solution in water removes resin, and, after decantation, sodium chloride precipitates the acid. Trimble adds lead acetate to the aqueous solution to precipitate colouring matter, filters, and extracts with acetic ether. The acid is re-dissolved in water, and extracted with ether to remove the last traces of gallic acid, and the aqueous solution finally dried in vacuo.

Detection.—1. Dilute H. SO. or HCl precipitates

conc. solutions.—2. FeCl,, a blue or green precipitate destroyed by long boiling, sol. weak mineral acids.-3. Lime-water precipitates the Ca salt. 4. Cinchonine sulphate precipitates white cinchonine tannate.—5. Gelatin forms leather and albumen also gives a precipitate. Alum and NH₄Cl render the precipitation more complete. An alcoholic solution of thymol, followed by conc. H.SO, yields a cose-coloured turbid solution (pyrogallol violet; gallic acid gives no colour: Saul, Ph. [3] 17, 387).—7. Iodine in presence of neutral salts gives a purple colouration (Nasser). 8. Acetate of lead acidulated with acetic acid ppis. tannic and not gallic acid (Guyard, Bl. 2, 41, 336).—9. NH₄Ol and NH₄ give a white precipitate rapidly becoming red, gallic acid a red colourstion only.-10. Cl water and NH, give a red colouration both with gallic and tannic acids. 11. K.FeCy, gives a similar reaction (Rawson, C. N. 59, 52-53).—12. In plants, Moll (A. a. 12, 496) detects tannins micro-chemically by treatment with 7 p.c. copper acetate for some days, then cuts sections, treats with a drop of 0.05 p.c. ferricacetate, washes with water and then alcohol to remove chlorophyll, and mounts in glycerin and looks for blue or green stain .-13. KCN gives a green colouration with tannin and none with gallic acid.—14. K_Cr₂O, gives a brown pp. with most tannins.—15. Saturated solutions of NaCl, CaCl, KOAc, and a number of other salts ppt. tannins from solution. -16. Conc. H₂SO₄ dissolves the dry tannins with a yellow colour, and on heating forms dark-red rufigallic acid and then black metagallic acid.-17. HNO, forms a yellow colour, and finally oxidises them to oxalic acid.—18. As Os heated with the dry tannins converts most into ellagic acid.—19. Most tannins are ppd. by the alkaloids.

Estimation of tannic acid. The methods devised for the estimation of tannic acid in vegetable extracts are very numerous, and may be grouped under the following heads:

- Gelatin or hide-powder absorption.
- 2. Titration with permanganate.
- 8. Precipitation with metallic salts.
- 4. Methods not included in the above.

For details of these various processes, vide Proctor, Textbook of Tanning; Trimble, The Tannins; Thorpe's Dictionary of Applied CHEMISTRY, and Rideal, Chemical Notes on Modern Tanning; The Assay of Tanning Materials; Industries, vol. xi. pp. 19, 139, 451. The two methods most generally employed are the hidepowder method and Löwenthal's permanganato

The hide-powder method is conducted as follows. A weighed quantity of the material is extracted with water and made up to a known volume. 100 c.c. of this solution is then evaporated, dried, and weighed to give the total solids present in the extract. Another portion of the same solution is agitated with, aspirated, or filtered through hide powder, and the total solids left in 100 c.c. of the solution again determined. The difference gives the quantity of tannic acid or matter which combines with gelatin per 100 c.c. of the solution (Fr. 24, 271).

The modified Löwenthal's process, which is now official in Germany, requires a standard solution of permanganate whose indigo value is known. A measured volume of the tannin solu-tion, together with a known volume of indigo solution, is then titrated with the permanganate solution. Another equal volume of the tannin solution is then agitated with hide powder or shaken with a gelatin and alum solution and filtered, and the filtrate, after indigo solution of known amount has been added, is titrated with the permanganate solution. The difference in the quantity of permanganate consumed is a measure of the tannic acid present. The various measure of teamine and present. The various tannins of commerce have different permanganate values; it is, therefore, necessary to standardise the permanganate for different tannin materials (Löwenthal, Fr. 16, 33; Kathreiner, Fr. 18, 118; Simaud, Fr. 22, 595; Saberdia, Fr. 51, 51) Schroeder, Fr. 25, 121).

Gallotannic acid C.H.O. Occurs in gall nuts and sumach.

Constitution. Constitution.—Co.O.C.,H.(OH), COOH (Schiff, A. 170, 43; Paul a. Kingzett, C. J. 33, 217).

Solubility.—Sol. acetone, glycerin, and oils;

insol. CS₂, CHCl₃, petroleum, and C₃H₃.

Compounds.—With gelatin contains 16.5 p.c. nitrogen = 34 p.c. tannin (Böttinger, A. 244, 227). (For other nitrogen values of gelatin-tannin compounds in leather, v. Rideal a. Trotter, S. C. I. 1891.) Penta - acetyl - compound C_pH₂(OAcO)₂CO.O.C_pH₂(OAcO)₂COOH [137°]. (Böttinger, B. 17, 1504).

Action of heat .- At 215° it forms pyrogallol, CO₂, and a trace of metagallic acid C₆H₄O₂. Strong heating at 240°-250° forms chiefly metagallic acid (Pelouze, A. 10, 159). Cold HNO, forms oxalie, trioxyglutarie, and trioxybutyrie acids (Böttinger, A. 257, 248). Boiling with KHO forms tannomelanic acid C₀H₁O₃; cold KHO and air form tannoxylic acid C₁H₂O₃ (Büchner, A. 53, 373). Hydrolysed by dil. H.SO, to gallic acid. Ferments also form gallic acid (van Tieghem, C. R. 65, 1992).

Oak bark. Tannic acid C, H, Oa.

Preparation .- The bark is extracted with alcohol, and the extract agitated with acetic ether and ether. Evaporate off ether, separate the precipitate of ellagic acid, and from residue separate gallic acid from the tannic acid by acetic ether and ether.

Properties .- Reddish-white powder. Sol. alcohol and acetic ether. Sl. col. ether and water. Heated to 130°-140°C. it forms an anhydride C₃₄H₃₀O₁, which is sl. sol. water; sol. alcohol and alkalis, and with conc. H₂SO₄ gives a second anhydride C₂₄H₂₂O₁₆. Heated with cone. HCl it evolves CH₂Cl, gives also the iodoform reaction. On dry distillation it forms pyrocatechin. Fused with KOH yields protocatechuic acid, pyrocatechol, and traces of phloroglucin (Etti, M. 1880, 262-278). When boiled with ether the The solution of the state of th

Etti and Löwe (l.c.).

Derivatives. Oak-red C14H10O62aq (Grabowbervatures.—Oak-red $C_{11}H_{10}O_{2}^{\circ}$ ad (Grabow-ski, A.145, 2); $C_{31}H_{32}O_{1}$, (Böttinger, A.240, 341). Böttinger has prepared various bromo-, acetyl, and benzoyl-derivatives (*Le.*) (Rochleder, A.63, 205; Böttinger, A.202, 270; B.14, 1598; Löwe, Fr.20, 210; Etti, M.4, 514; Garbowell, A.152Grabowski, A. 115, 2).

Fraxitannic acid C26H22O14. In ash-leaves. Forms an anhydride $C_{2n}^{-1}H_{2n}^{-1}O_{1n}$, a henzoyl-compound $C_{2n}H_{2n}O_{1n}(OB_3)$, a promaetyl-compound $C_{2n}H_{2n}(OAc)_1O_{1n}$, a bromaetyl-compound $C_{2n}H_{2n}(OAc)_1O_{1n}$, and a similar nitrocompound. On heating with $Ba(OH)_2$ it forms protocatechuic acid and other products. On heating to 100° it loses * mol. H.O, forming an anhydride C24H20O12 (Gintl a. Reinitzer, M. 3,

745 et seq.).

The following table gives the source of the principal tannins which have been investigated, and references to the papers in which a descrip-

tion will be found.

TANSY OIL. The essential oil, obtained by distillation of the tansy (Tanacetum vulgare) contains 1 p.c. of a terpene C_0H_{10} (155°-160°), 26 p.c. of an alcohol $C_{10}H_{10}$ (155°-160°), 26 p.c. of an alcohol $C_{10}H_{10}$ (Bruylants, J. Ph. [4] 26, 393; B. 11, 449; cf. Persoz, C. R. 8, 33). Tanacetyl hydride $C_{10}H_{10}$ (195°-196°), 8.G. 4.918, V.D. 5·1, is converted by H.SO, into cymene. It reduces ammoniacal AgNO_s, forming a mirror. NaHSO_s forms crystalline CioHisNaSO. Split up by water into the parent substances

TANTALATES v. TANTALUM, ACIDS OF, AND

TANTALUM. Ta. At. w. c. 182 (exact value not known). Mol. w. not known. Ta has not been isolated.

Occurrence .- Tantalates occur in a few rare minerals, generally associated with niobates; tantalite contains from 35 to 75 p.c. Ta₂O₅, columbite from 13 to 36 p.c., yttrotantalite from 6 to 47 p.c., and a mineral com Western Australia, recently analysed and called stibiotantalite, c. 52 p.c., Ta,O, (Goyder, C. J. 63,

1076).

History. - A short account of the researches that led to the identification of two distinct oxides in tantalite is given in the article Nicobium (vol. iii. p. 505). Marignac (C. R. 60, 234, 1355) gave the formula Ta₂O, to oxide of Ta, which had been represented by Rose as TaO₂. Deville determined the V.D. of the chloride, and deduced the molecular formula TaCl, (C. R. 56, 891). By heating Na, TaF, with Na, H. Rose (P. 99, 69) obtained a black powder, probably a mixture of Ta and oxides of Ta. Berzelius (P. 4, 6) also obtained very impure Ta; Marignac (Ar. Sc. 1868) failed to isolate approximately pure metal.

Preparation of impure Ta.—Very finely-powdered tantalite is fused with three times its weight of KHSO,, in an iron or platinum crucible, until completely dissolved. After cooling, the fused substance is powdered and treated with boiling water, whereby sulphates of K, Fe, and Mn are dissolved out; the insoluble portion is washed, and then digested with yellow ammonium graphila machine allegated. nium sulphide, whereby sulphides of Sn and W are dissolved, and FeS remains mixed with Ta, 0, and Nb, 0. The residue is washed thoroughly, and digested with HClAq to remove FeS, and the portion insoluble in HClAq is thoroughly washed with boiling water until it is white. The mixture of Ta₂O₃ and Nb₂O₅ thus obtained is dissolved in HFAq in a platinum dish, the solution is heated to boiling, and a quantity of KHF, is added equal to one-fourth of the weight of mixed Ta₂O₅ and Nb₂O₅ used; the liquid is evaporated until 1 g. of the mixed oxides is present in about 7 c.c. and allowed to cool; the prismatic crystals of K.TaF, that separate are washed with cold water until the washings give a yellow pp., without any shade of red, after standing for two hours with tincture of galls. The K,TaF, thus obtained is heated, in a platinum dish, with rather more than its m a pastnum cisu, with rather more than its weight of pure cone. H₂SO₄, whereby KHSO₄, HF, and Ta₄O₄ are formed; the HF is removed by heat, and the KHSO₄ by repeated washing with water (Berzelius, P, 4, 6; of H. Rose, P. 144, 64, 70) 144, 64, 72).

Lawrence Smith (Am. 5, 44) recommends to warm 5 g. of very finely powdered tantalite, dried at 150°, in a platinum basin with a little water and 8 to 10 c.c. very conc. HFAq, to filter when reaction is completed, add a little water to the filtrate and evaporate nearly to dryness, to warm with excess of conc. pure H₂SO₄, and after the acid has been almost wholly removed by heating, to place the residue in c. 500 c.c. dilute HNO₂Aq (L. M., C. N. 51, 289, 304), and boil until Ta,O, and Nb,O, are ppd. By dissolving in HFAq, adding KHF, and proceeding as described above, Ta,O, is obtained free from

Nb₂O₃.

The pure Ta₂O₃ obtained by one of the preceding methods is dissolved in HFAq, in a platinum vessel, the solution is heated to boiling, and 708 pts. by weight of KHF₂ are added for 100 pts. Ta₂O₅ used. The solution is evaporated and allowed to cool; the crystals of K₂TaF, are washed with a little cold water, dried, mixed with c. half their weight of potassium, and heated in an iron crucible, the mixture of K, TaF, and K being covered with KCl. The contents of the crucible, after cooling, are added, little by little, to water; the black powder that separates is washed with water, and then with dilute alcohol and dried (Berzelius, P. 4, 6). The black powder is probably a mixture of Ta and oxides of the metal. Berzelius found that 100 pts. took up 17 pts. O when heated in air, 100 pts. pure Ta require 22 pts. O to form Ta,O. H. Rose (P. 99, 69) obtained a black powder-probably Ta mixed with oxides-by reducing Na2TaF, by heating with sodium.

Properties and Reactions .- The black powder obtained by Rose was a good conductor of electricity; it glowed when heated in the air, and slowly formed Ta,O,; it was insoluble in acids, scowed; heated in a stream of Cl it burnt to TaCl. Oxidation was effected by molten alkalis or alkali carbonates. The S.G. of a specimen containing c. 40 p.c. acid sodium tantalate was

The at. w. of Ta was determined by Marignac The at. w. of Ta was determined by Marignac (A. 140, 153; Suppl. 4, 351 [1865]) by decomposing K.TaF, and (NH₄),TaF, by H₅SO₄ and determining the quantities of Ta₂O₅ and K₂SO₄ produced. The values obtained varied from 180·1 to 185·2. H. Rose in 1856 (P. 99, 80) analysed TaCl₅ by decomposing by water, ppg. Ta₂O₅xH₂O by NH₂Aq, and estimating Cl in the filtrate. His results showed marked discrenancies pancies.

Ta is metallic in its physical properties, so far as may be judged from the impure specimens that have been prepared. Ta₂O₅ dissolves in HFAq, probably forming TaF. No salts are known to be formed by replacing the H of an oxyacid by Ta. In all the salts of Ta that have been isolated, other than the haloid compounds, Ta forms part of the negative radicle. the fifth member of the even-series family of Group V.; it is closely related to Nb, and less closely to N, P, V, As, Sb, Di, Er, and Bi. The only compound of Ta whose V.D. has been determined is TaCl,; in this molecule the atom of Ta is pentavalent (v. Nitrogen group of Eigments, vol. iii. p. 571).

Detection and Estimation,-Tantalum com-

pounds form potassium tantalate when fused ! with KOH, and the fused mass dissolves in water. The product obtained by fusion with NaOH dissolves in water to a clear liquid only after NaOH has been removed by washing, as sodium tantalate is insoluble in much NaOllAq. Addition of acid to an aqueous solution of an alkali tantalate, followed by boiling, ppts.
Ta.O. xH.O more or less completely. By adding HClAq to a solution of an alkali tantalate, and placing zinc in the solution, no blue colour is produced (cf. Niosium, detection of, vol. iii. p. 506). According to Levy (C. R. 103, 1074), an amethyst colour is produced by adding a very small quantity of Ta₂O₂, to a solution of resorcin in H CO 4. To 2. to in H₂SO₄Aq. Ta is estimated as Ta₂O₅; the process is sufficiently indicated under Prepara-

Action was to

Tantalum, acids of, and their Salts. TagO, reacts with molten alkalis, and alkali carbonates, from salts which may be regarded as derived from various hydrates of Ta₁O₂. Two hydrates are obtained, Ta₂O₂2H₂O and 2Ta₂O₂3H₂O, by decomposing TaCl, by a little water, and by fusing Ta₂O₂ with KHSO₄ and washing with water (v. Tantalum, oxides and hydrated oxides of, p. 640). The first of these H₄Ta₄O₁, corresponding with H₄Pa₄O₁, and the second may be formulated H₄Ta₄O₁₂. The tantalates that have been examined do not seem to be derived from either of these compounds, but from the hypothetical acids HTaO₃, corresponding with HPO₃ and HNO₃, and H₈Ta₆O₁₉ (=3Ta_O₃4H₂O₃. Tantalates are not produced by neutralising Ta₂O₃...H₂O₃ but by fusing Ta₂O₃ with alkalis, or by double decomposition from alkali salta.

TANTALATES. The tantalates belong to the form xTa₂O₃yMO, where $M = (NH_4)_2$, Mg, Hg_2 , K_2 , Ag, or Na,; of those that have been fairly fully examined, some correspond with the metaphosphates and meta-niobates M¹XO₂, and others belong to the more complex form M¹₈Ta₈O₁₉. Some of the alkali tantalates dissolve slightly in water, the other tantalates are incomplex. insoluble. Fluotantalates and fluoxytantalates are also known (v. infra). The tantalates have been investigated chiefly by H. Rose (P.

100, 417) and Marignac (Bl. [2] 6, 111, 118).

Annonium tantulate. A pp. is obtained by adding NH Cl to solution of Na Tu O I g. x H O. but the composition of the pp. is not known with certainty.

Magnesium tantalate. By adding MgSO4Aq to solution of Na, Ta,O10.xH2O a crystalline pp. was obtained which, after drying at 100°, had the composition Mg, Ta,O₁₉, 9H₂O. A crystalline Mg tantalate was obtained by Joly (C. R. 81, 266, 1266) by fusing Ta,O, with MgCl₂.

Mercurous tantalate. A brown, amorphous compound, perhaps Hg.Ta.O.p.xH.O. is formed by adding HgNO.Aq to solution in water of Na, Ta, O, xH2O.

Polassium tantalates. (1) K, Ta, O,, 16H, O, this salt is obtained by fusing Ta, O, with KOH, dissolving in water, and crystallising. (2) KTaO,: this salt, potassium metatantalate, is formed by heating the other tantalate, alone or with (NH₄)₂CO₂, and then treating with water. Silver tantalate. The yellowish white pp.

obtained by adding solution of a salt of Ag to solution of Na₂Ta₂O_{1p.2}H₂O, and drying at 100°, has the composition Ag,Ta₂O_{1p.2}H₂O.

Sodium tantalates. The meta-salt

NaTaO₃ is obtained by fusing Ta₂O, with Na₂CO₃, and washing with water. A salt of the composition Na₂Ta₂O_{1p.2}H₂O (x = 25 and 30) is prepared by fusing Ta₂O₃ with NaOH, dissolving in water and areallising. in water, and crystallising.

FLUOTANTALATUS. (Tantalifluorides.) These salts may be regarded as compounds of TaF. with metallic fluorides, or as metallic derivatives of the hypothetical acid H.TaF,; they are prepared by dissolving Ta,O, in HFAq, adding metallic fluorides, and crystallising; some of them are formed by dissolving Ta,O, and a metallic oxide in HIAq (Marignac, A. Ch. [4] 9, 276; Berzelius, P. 4, 6).

Ammonium fluotantalate (NH.) TaF, is obtained by evaporating a solution of NH.F in solution of TaF, in HFAq, and evaporating; the salt is aystalline and easily soluble in

Copper fluotantalate CuTaF, forms blue, deliquescent, rhombic prisms; it is prepared by dissolving CuO and Ta₂O₃ in excess of HFAq, and evaporating.

Potassium fluotantalate K₂TaF, forms white needles by dissolving KHF₂ in solution of Ta₂O₈ in HFAq, evaporating, and crystallising from hot water. The salt is very slightly soluble in cold water, but dissolves easily in hot water. On long boiling, K., Taf-Aq gives a white pp., probably having the composition K., Taf-Q., Fig. (=2Taf-, Ta, Q., 4KF). By dissolving K., Taf-, in warm 4 p.c. H., Q., Aq with a little HfAq and allowing to cool, Piccini (Zcit. für anor . Chemie, 2, 21) obtained crystals of the fluoxytantalate

K. Tao.F., H.O. (-Tao.F., 2KF.H.O).

Solium fluotantalate Na, TaF., H.O; obtained, as white crystals, by dissolving Na, Ta, O,, in HFAq, evaporating, and drying at 100° the salt that separates.

Zinc fluotantalate ZnTaF, 7H2O; a deliquescent salt, obtained by dissolving ZnO and Ta,O, in excess of HFAq and crystallising.

Tantalum, alloys of. By heating K₂TaF, with Al, and washing with HClAq, Marignac (P. 100, 145) obtained a grey power, S.G. 702. By heating to whitness, in a carbon crucible, a mixture of Ta.O., and iron filings, an alloy of Ta and Fe was obtained resembling pig iron (Gahn, Berzelius a. Eggertz, S. 16, 437)

Tantalum, bromide of, TaBr,. A yellowish, crystalline compound, obtained by heating a mixture of dry Ta₂O₅ and C in vapour of Br, and removing excess of Br by a long-continued stream of dry CO₂; decomposed by water to HBrAq and Ta₂O₅xH₂O (H. Rose, P. 90, 456; 99, 75). The conditions of preparation are similar to those in making TaCl, (q. v.).

Tantalum, carbide of. By heating TaN (v. TANTALUM NIFTUE) with C to the melting-point of steel, N is given off and the nitride in partly converted into brass-yellow coloured TaC₂ (Joly, Bl. [2] 25, 206).

Tantalum, carbonitride of. Joly (Bl. [2] 25. 206) obtained a substance, to which he gave the formula 10TaC.TaN, by very strongly heating a mixture of Ta₂O₄ with C and soda.

Tantalum, chloride of, TaCl,. Mol. w. c. 859 (not determined with great accuracy, as at. w. of Ta is doubtful). V.D. 185 at 360° (Deville a. Troost, C. R. 64, 294). Melts at 211°, and boils at 242° at 753 mm. pressure (D. a. T., l.c.). Only one chloride of Ta has been isolated.

Preparation .- About 5 g. pure dry Ta,O, is mixed with a considerable excess of dry sugar or starch, and the mixture is completely charred by heating in a closed crucible; the charred mass is broken into small pieces, which are heated to redness and placed, while red hot, in a rather wide tube of hard glass that is quickly heated to redness while a stream of thoroughly dried CO₂ is passed through it as long as any trace of moisture is given off from the contents of the tube; the tube is then allowed to cool, the current of dry CO, being maintained; when the tube is cold a stream of dry Cl is passed through it, and when every part of the apparatus is filled with Cl (but not until then) the contents of the tube are heated. TaCl, forms immediately behind the carbonaceous matter, as a pale-yellow solid; when the reaction has entirely ceased and CO is no longer evolved, the TaCl, may be sublimed into another part of the tube, a plentiful stream of dry Cl being maintained during the process. If sublimation is attempted before the whole of the Ta,O, has been chlorinated, before the whole of the La₁U₃ has been chlorinated, a part of the TaCl, is decomposed by the CO, with re-formation of Ta₂O₃. If there should be any air in the tube during the process a white sublimate is formed which is probably an oxychloride (H. Rose, P. 90, 456; 99, 75). Should the Ta₂O₃ used contain any WO₃, the sublimate obtained is reddish; by gently heating, the greater part of the red WOCl, may be removed, as it is rown redshift by D. as it is more volatile than TaCl.

Demarcay obtained TaCl, by passing vapour of CCl, over Ta₂O, heated to redness (C. R. 104,

Properties and Reactions. - Pale-yellow prismatic needles, melting at 211°, and boiling at 242° under the pressure of 753 mm.; begins to vaporise at 144°; V.D. 185 at 860° (Deville a. Troost, C. R. 64, 294). Decomposes in ordinary air, giving off HCl and becoming covered with a are, giving on its and comming covered wan acrust of crystalline Ta,O_s. Decomposed entirely by water to HClAq and Ta,O_s.xH₂O. Conc. H₂SO₄ causes evolution of HCl, and forms a somewhat turbid solution from which Ta,O_s.xH₄O separates on boiling; by adding the solution of the solution of the whole water to this solution, and boiling, the whole of the Ta is precipitated as Ta₂O₅ "H₂O. Conc. HClAq reacts similarly to H₂SO₀, but only a portion of the Ta₂O₀, xH₂O is ppd. on adding water and boiling. TaCl, is partly dissolved by heating with KOHAq. TaCl, is stiluble in absolute alcohol; H₂SO₂Aq does not ppt. Ta₂O₂, xH₂O from this solution.

No double compounds of TaCl, with KCl or NaCl-similar to those of TaF,-have been ob-

Tantalum, fluoride of. Ta,O,.xH,O dissolves in HFAq; neither boiling, nor adding H₂SO,Aq to the solution, ppts. Ta₂O₂. The solution in HFAq gives off vapours on evaporation that pro-bably contain TaF₁; by evaporating at a low 99, 75). By evaporating in vacuo a solution of Ta₂O₄.xH₂O in HFAq, Marignae obtained a white amorphous mass—probably an oxyfluoride—and then small crystals that were likely

TaF, combines with some metallic fluorides, forming fluotantalates (q.v., p. 639).

Tantalum, haloid compounds of. The only haloid compounds of Ta that have been isolated are TaCl, and TaBr. The former has been gasified, and the formula is molecular. also probably exists in solution of Ta2O, xH2O in HFAq. There is no reaction between I and TaO, mixed with C even at a very high temperature. TaCl, and TaBr, are readily decomposed by water, with formation of TaO, xHO and HXAq. Double compounds of TaF, with some metallic fluorides are known; they belong to the form M12TaF, (v. FLUOTANTALATES). Oxyhaloid compounds probably exist, but none has been iso-lated with certainty.

Tantalum, nitrides of. TaCl, absorbs NH, at the ordinary temperature; by heating the product in NH₃, Joly (Bl. [2] 25, 206) obtained an amorphous, yellow solid, to which he gave the formula Ta,N. By heating this yellow solid to redness in very dry NH₃, a black solid was obtained which, after washing with water and drying, had the composition TaN. This black solid conducts electricity; 'heated in air it burns to Ta₂O₃; NH₃ is given off by the action of molten KOH; it is insoluble in acids, except in a mixture of HFAq and HNO₃Aq (Joly, *l.c.*; cf. H. Rose, P. 100, 166).

Tantalum, nitrocarbide of; v. TANTALUM CARBONITRIDE, p. 639.

Tantalum, oxides and hydrated oxides of. The oxide Ta₂O₅ has been isolated, and also a hydrate of this oxide Ta₂O₂.2H₂O, and probably also another hydrate 2Ta₂O₃.3H₂O. The existence of another oxide, TaO2, is doubtful.

TANTALUM PENTOXIDE Ta,O,. (Tantalic anhydride. Tantalic oxide.) The preparation of this compound from tantalite is described at the the beginning of this article under Preparation of tantalum (p.638). Ta₂O₅ is also obtained by decomposing TaCl₅ by water, or by adding H₂SO₄Aq to solution of a tantalate and boiling, and then heating the Ta₂O₃.xH₂O thus ppd Ta₂O₃ is a white powder; it has not been fused; by heating with boric acid or microcosmic salt in a porcelain oven it is obtained in rhombic prisms (Ebelmen, A. Oh. [3] 33, 34; Nordenskjold a. Chydenius, J. 1860. 145). S.G. o. 7-6 (Marignac, Ar. Sc. 1868; Deville, C. R. 56, 894). Ta₂O, is insoluble in acids except HFAq; after being very strongly heated, it is insoluble in HFAq. Ta₂O₅ dissolves in molten alkalis, also in molten KHSO₄ (v. Tantalates, p. 639).

HYDRATES OF TANTALUM PENTOXIDE. By de-composing TaCl, by water, Ta₂O₄xH₂O is obtained, which, after very thorough washing with water, then with NH, Aq to remove adhering HCl, and finally with water, and drying at 100° gives off from 6 to 7.8 p.c. water when heated to redness. The formula 2Ta₂O₂.3H₂O requires 5.7 p.c. H₂O, and the formula Ta₂O₄.H₄O requires 7.5 p.c. H₂O. It is doubtful whether one or more temperature, Rose obtained crystals that dis-solved easily in water, and were partly vaporised when heated, leaving some Ta₂O₄ (P. 90, 456; a pp. of Ta₂O₄xH₂O is obtained, which, when

thoroughly washed and dried at 100°, is said | inoroughly washed and dried as 100, is said to be Ta₂O₂.2H₁O = H₄Ta₂O₄ (H. Rose, P. 100, 417). Strong acids, such as H₂SO₄, HNO₃, and HCl, ppt. Ta₂O₂.xH₂O apparently in combination with the acid used as precipitant from solutions of alkali tantalates; weak acids ppt. insoluble alkali tantalates.

TANTALUM DIOXIDE TaO. (Tantalum tetroxide [Ta_O]) The isolation of this oxide is doubtful. Berzelius obtained a brown powder by heating Ta₂O₃ to redness in a carbon crucible; it was not dissolved by any acids, not even by a mixture of HNO, Aq and HFAq; when strongly heated in air it gave Ta,O, (P. 4, 20).

Tantalum, oxyfluoride of. The white powder formed by decomposing K.TaF, by boiling water may be an oxyfluoride, according to Marignac (A. Ch. [4] 9, 276).

Tantalum, salts of. No salt has been isolated

by replacing the H of acids, except HCl and HF, by Ta. When alkali tantalates are decomposed by strong acids such as HCl, HNO, or H,SO, the ppd. Ta,O,xH,O retains some of the acid used as precipitant; compounds of Ta,O, with

these acids are perhaps formed.

Tantalum, sulphide of. By strongly heating Ta.O, in CS, vapour, also by heating to redness a mixture of vapour of TaCl, and H.S, a yellowish black solid is obtained, which has the composition TaS. according to Berzelius (P. 4, 6; v. also II. Rose, P. 99, 575). Roasted in air, this solid gives Ta, 23; heated in Cl it produces TaCl, and S.Cl.; conc. IINO, Aq oxidises it to Ta, O, xH, O and H, SO, Aq. TaS, does not combine with alkali H.SO, Aq. TaS, does not combine with alkan sulphides (R., l.c.); fused with KOH, it forms K.S and potassium tantalates. M. M. P. M.

TARCHONYL ALCOHOL Con H102O (?). Obtained from the leaves of Tarchonanthus camphoratus by extracting with alcohol (Canzoneri a. Spica, O. 12, 227). Silvery scales, insol. water and ether. Converted by PCl, into a chloride [70°] crystallising in small plates (from

alcohol)

S.G. 1-764 (Schiff, A. 113, 189); 1-74 (Buignet, J. 1861, 15); 1-7594 (Perkin). S. 115 at 0°; 132 at 15°; 343 at 100° (Leidie, Fr. 22, 269; G. R. 95, 87; cf. Schiff, J. 1859, 41; Maisch, J. 1865, 392). S. (alcohol) 25-6 at 15°. S. (ether) 4 at 15° (Bourgoin, Bl. [2] 29, 214; A. Ch. [5] 13, 400). [a]_p = 15.06 - 131p in a p per cent. solution (Landolt, B. 6, 1075; Lippmann, B. 24, 3300). H.F. 372,000 (Von Rechenberg). Heat of solu-tion: -3454 at 9° (Pickering, C. J. 51, 376).

Occurs free or as K or Ca salt in grape-juice, tamarinds, unripe mountain-ash berries, madderroot, potatoes, Jerusalem artichokes, sorrel, gherkins, mulberries, pine-apples, black pepper, the leaves of Chelidonium majus, the bulbs of Scilla maritima, in beet-juice, and in many other

Formation .- 1. Mostly together with racemic acid, by oxidation of saccharic acid, dextrose, cane-sugar, milk-sugar, starch, gum arabic, and sorbin by nitric acid (Dessaignes, A. Suppl. 2, 242; Hornemann, J. 1863, 381; Kiliani, A. 205, 175).—2. By the action of sodium-amalgam on Vol. IV.

an alcoholic solution of oxalic ether (Debus, A. 166, 124; C. J. 24, 376). The product is probably inactive tartaric acid.

Preparation .- Powdered chalk is added to a boiling solution of cream of tartar; the filtrate is ppd. by calcium chloride, and both pps. decomposed by the proper quantity of boiling dilute H₂SO₄. The filtrate from CaSO₄ is evaporated to crystallisation. It may be purified by saturating with CaCO₃, digesting with ZnCl, and decomposing the zine salt by H.S (Ficinus, Ar.

Ph. [3] 14, 310).

Properties .- Monoclinic prisms, with hemihedral facets; a:b:c = 785:1:805; $\beta = 79^{\circ}$ 43'. Dextrorotatory, the rotation being dependent on the concentration of the solution, and being also greatly affected by the presence of alcohols, acids, and other substances in the solution (Landolt, B. 13, 2329; Biot, J. 1850, 169; Pribram, M. 9, 25. 15, 2522; BIOL, J. 1800, 105; I Horam, A. 6, 485; B. 22, 6; Long, Am. S. 86, 351; Thomson, J. pr. [2] 35, 146). Sodium molybdate in the proportion of Nu MoO, to 2C, H₂O₆ increases the rotation 37 times, while ammonium molybdate (1) and the rotation of trybaric solid (1 mol.) increases the rotation of tartaric acid (3 mols.) 56 times (Gernez, C. R. 104, 783; 105, 803). Lithium and magnesium molybdate also increase the rotation. Sodium tungstate also increases the rotation, the maximum effect being 22 times (Gernez, O. R. 106, 1527; 108, 942). Crystals of tartaric acid are strongly pyro-electric. An aqueous solution of tartario acid is ppd. by baryta, lime, and lead acctate. Potassium salts, when the solution is not too dilute, form a crystalline pp. of KC, H,O,; the formation of the pp. being promoted by rubbing the sides of the vessel with a glass rod and by the addition of alcohol. CaCl, ppts. CaA', from neutral solutions of tartrates; the ppn. is hindered by ammonium salts. Calcium tartrate dissolves in KOHAq and is re-ppd. in gelatinous form on boiling. Reduces ammoniacal AgNO, forming a mirror; the solution then contains oxalic acid (Claus, B. 8, 950). Tartaric acid prevents the ppn. by alkalis of the oxides of Al, Bi, Ni, Co, Cr, Cu, Fe, Pb, Pt, and Zn, even on boiling (Aubel a. Ramdohr, A. 103, 33; Grotho, J. pr. 92, 175). 1 mol. acid prevents the ppn. of 1 mol. Cu(OII). A solution of tartaric acid, coloured by a drop of K2CrO4, gradually becomes colourless (difference from citric acid) (Salzer, B. 21, 1910). A saturated solution of potassium bichromate is slowly turned coffee-brown by tartaric (but not by citric) acid (Cailletet, C. C. 1879, 14). Boiling alkaline KMnO, is turned green, and finally brown, by tartaric acid, but only green by citric acid. Decolourises KMnO, in acid solution. When H,SO is present, twice as much KMnO, must be added to produce a permanent red colour as when it is absent, for in the latter case MnC, H,O, is formed (Fleischer, B. 5, 350). Tartaric acid gives an odour of burnt sugar when heated till carbonised. A crystal added to conc. H₂SO₄ containing 1 p.c. resorcin gives a red colour on warming (difference from citric and maleic acids) (Mohler, Bl. [3] 4, 728). To detect small quantities of tartaric soid in

presence of citric acid. Add about 1 g. citric acid to a 20 p.c. solution of molybdate of amacid to a 20 p.c. solution of more drops of a dilute solution of H₂O₂, and heat for three minutes on the water-bath. If the citric acid is pure the solution remains yellow. If 0-1 p.c. or more of tartaric acid is present, the liquid become blue (Crismer, Bl. [8] 6, 23).

Redctions.—1. Melts at 185°, changing to the isomeric metatartaric acid. The metatar.

taric soid may be reconverted into tartaric scid by boiling with water (Grosjean, C. J. 43, 334).— 2. At 140°-150° water is eliminated and ditar, 2. At 140°-150° water is eliminated and ditar-trylic acid C_aH₁₀O₁₁ is formed. On further heating soluble tartaric anhydride (tartrelic acid), and then insoluble tartaric anhydride, are formed. On further heating the products of distillation (from 250 g.) are pyruvic acid (9 g.), pyrotartaric soid (2 g.), formic acid (4 g.), resins, aldehydes and volatile acids (2 g.), and tarry bodies (3 g.) (P. Liebermann, B. 15, 428). 'Dipyrotartracetone' C₆H₁₂O₂ (230°), a colourless liquid, with aromatic odour, is among the products of the distillation of tartaric acid. It combines with bromine (Bourgoin, C. R. 86, 674).-8. By heating tartaric acid (10 pts.) with water (1 pt.) at 175° it is convexted into racemic acid and inactive tartaric acid. At 165° there acid and inactive tartaric acid. At 105 there is a greater yield of the inactive acid (Jungfleisch, J. 1872, 515). Heated with more water at 150° it yields CO₂ and pyrotartaric acid (Wedard, C. C. 1888, 889).—4. Potash-fusion vields acetic and oxalic acids. -5. Oxidation by CrO₂, KMnO₄, PbO₂ or MnO₂, and H₂SO₄ yields CO₂ and formic acid. The rate of oxidation has been studied by Krutwig (Z. P. C. 2, 787). By slow oxidation by HNO, tartronic acid may be obtained.—6. Reduced by HI and P to malic and succenic acids.—7. PCl, forms chloro-fumario and successions acids. —7. PCl, forms chloro-fumatic chloride.—8. FeSO₄ at 100° yields iso-arabic acid $C_bH_1O_3$, a thick dextrorotatory syrup, $[a]_b = 20^{\circ}$, yielding the salts CaA'_2 9aq, $Ca_2OA'_2$ 8aq, PbA'_{22} and $Pb_2A'_2O_2$ (Ballo, B.22,750).—9. Chloral forms $C_bH_1Cl_2O_3$ [124°], crystallising from chloroform in small needles, insol. water, sol. warm alcohol and ether (Wallach, A. 193, 46).—10. On submitting tartaric acid to electrolysis and treating the syrupy mass with phenyl-hydrazine, glyoxal-osazone [160°] and glyoxal-carboxylic osazone [218°] are obtained (Friedel a. Combes, Bl. [8] 8, 770).—11. On adding powdered tartaric acid to fused glucose tartaric glucoside is obtained (Guyard, Bl. [2] 41, 291; cf. Berthelot, A. Ch. [3] 54, 78).—12. m-Anido-benzoic acid at 160° forms 'tartylo-dibenzamio' acid C_{1n}H₁₀N₂O₂
i.e. (CO₂H.C₆H₁NH.CO)₂C₂H₂(OH)₂, a colourless powder, insol. water, sol. hot alcohol. Its alkaline salts form yellow solutions in which Cu(OAo)₂ ppts. C_{1n}H₁₄(CuOH)₂N₂O₂. On heating to 190° it yields the anhydride C_{1n}H₁₄N₂O₂, a greenish-yellow powder, converted by an alcoholic solution of aniline into tartranil dibenzamic

CO₂H.C₆H₄.N<CO⁽⁾CH.CH(OH).CONHPh [200°] (Schiff, A. 232, 156; G. 16, 28). Another product of the action of tartaric acid on mamido-benzoic acid is 'tartryl-benzamic' acid

CO.H.CH(OH).CH(OH).CO.NHC.H,.CO.H, which crystallises from water in pale-yellow aggregates, yields an acetyl derivative and an anhydride 'tartranbenzamic' acid C11H,NO. orystallising from water in green plates, forming C₁₁H,BaNO₄ and C₁₁H,CuNO₅, and converted at 210° in 'benzamtartridic' acid by dehydration. A warm alcoholic solution of aniline converts 'tartranbenzamic' acid into 'tartranilbenzamic'

acid [245°], which yields an acetyl derivative [198°]. 'Tartryl-benzamic' acid heated with dry amido-benzamide at 140° forms the compound amido-benzamide at 140° forms the compound $C_LH_2(OH)_4(OC)$. MLC₄H₂OONH₂)₂ a white powder, insol. water, sl. sol. alcohol, and yielding $C_{11}H_{11}$ CuN₂O, aq.—18. Glycerin at 100° yields the compounds $C_3H_3(OH)_2$.O.C. $_4H_2O_3$ and $C_4H_4(OH)(OC,H_2O_3)_2$ (Desplats, J. 1859, 500). Glycerin at 140° gives $C_{11}H_{11}O_{12}$ and $C_{13}H_{12}O_{18}$ —14. Erythrite at 100° forms $C_{12}H_{12}O_{11}$, which gives $C_{13}(C_{12}H_{13}O_{11})_2$ 3aq (Berthelot, A. Ch. [3] 54, 84). 15. Quercite at 120° forms $C_2H_{12}O_{12}$, which gives $C_{13}C_2H_{12}O_2$ 2aq.—16. Pinite at 120° forms $C_{23}H_{23}O_{13}$, which gives $C_{13}H_{23}O_{13}$, which gives $C_{13}H_{23}O_{13}$, which gives $C_{13}H_{23}O_{13}$, which gives $C_{13}H_{23}O_{13}$, which gives $C_{23}O_{23}H_{23}O_{33}$, which gives $C_{23}O_{23}H_{23}O_{33}$.—17. Mannita crystallising from alcohol in plates.

Estimation.—Methods for estimating tartaric acid have been described by Scheurer-Kestner, C. R. 86, 1024; Berthelot, Fr. 3, 216; Vogel a. Braun, Fr. 7, 149; Kissel, Fr. 8, 409; Fleischer, Braun, Fr. 7, 149; Kissel, Fr. 8, 409; Fleischer, Fr. 12, 328; Oliveri, G. 14, 453; Piccard, Fr. 21, 424; C. Schmitt a. Hiepe, Fr. 21, 539; Amthor, Fr. 21, 195; Nessler a. Barth, Fr. 21, 60; 22, 159; Kayser, Fr. 22, 123; 23, 29; Musset, Fr. 24, 279; Ferrari, Fr. 24, 279; Varington, C. J. 28, 25; Grosjean, C. J. 35, 341; Klein, Fr. 24, 379; Bornträger, Fr. 25, 327; 26, 699; Gantter, Fr. 26, 714; Von Lorenz, Fr. 27, 8; Philips. Fr. 29, 577; Goldenberg. Fr. 27, 28; Fr. 27, 8; Philips, Fr. 29, 577; Goldenberg, Fr. 22, 270; Heidenhain, Fr. 27, 681; Weigert, Fr. 23, 357; Haas, C. C. 1888, 1045; Ward, Ph.

[3] 19, 380.

Salts (Berzelius, P. 19, 305; 36, 4; A. Ch. [2] 67, 303; Werther, J. pr. 32, 383; Dumas a. Piria, A. Ch. [3] 5, 353; De la Provostaye, A. Ch. [3] 3, 129).—(NH₁).A''. [a]_D = 33.7° in a 1.2 p.c. solution (Sonnenthal, M. 12, 603). Efflorescent monoclinio prisms, v. sol. water; $a.bc. = .868:1:1\cdot244a = 88^\circ9'$. Givcoff NH₃ in air. Yield succinic acid on fermentation (Koenig, G.11.189). $-(NH_4)HA''$. $[a]_D = 25.7^{\circ}$ (Landolt). Minute lamine, sl. sol. cold water. Forms with ammonium Monoclinio crystals; $a:b:c=.402:1:1\cdot109$; $a=75^{\circ}12'$.—KHA". Cream of tartar. [a]_n=22° in a 4 p.c. solution. 100 g. solution contain :369 + 000569f grammes at f (Blarez, C. R. 112, 434, 808). S. 25 at 0°; 4 at 10°; 55 at 20°; 1·13 at 40° (Chancel, C. R. 60, 408; of Alluard, 1.13 at 40° (Chancel, C. R. 60, 408; cf. Alluard, C. R. 59, 500). Obtained by crystallisation of argol, which is deposited during vinous fermentation. Efflorescent, apple-green crystalline powder
(Fabian, A. 103, 248).—CoOl(HA"),5NH,22aq
(Jörgensen, J. pr. [2] 18, 239).— ZnA"2aq
(Schiff, A. 125, 146).—Zn,2C,H,O, 3aq. Powder,
insol. water.—Cr(OH)A". Violet flakes, turning
derk blue over H. 50, (Schiff, A. 195, 145). insol. water.—Cr(OH)A". Violet flakes, turning dark-blue over H₂SO₄ (Schiff, A. 125, 145). At 220° it yields CrC, H₂O₆.—K(CrO)A" 3 aq (Malaguti, C. R. 16, 457).—(UrO₂)A" 3 aq (Péligot, A. 56, 231).—K₂(UrO₂)A"₂ (dried at 200°).—(SbO)₂(UrO₂)A"₂ 3 aq.—SnA". Minute crystals.—K(FeO)A"4 or 5 aq. Propared by digesting cream of tartar with water and Fe(OH)₃. Brown scales well by transmitted light, Acids part from scales, red by transmitted light. Acids ppt. from its solutions a basic salt, sol. excess. — NH₄(FeO)A"4 (or 5) aq. — Fe₂A"₅. — FeA". Formed by boiling tartaric acid with water and iron wire (Méhu, N. J. P. 40, 257). Minute crystalline powder. S. 877 at 45.6° (Dulk, A. 2, 62).—K(MnO)A" 4aq (Descamps, Z. 1870, 317). Ag.A'. Amorphous curdy pp. got by adding AgNO, to a cold solution of Rochelle salt. Crystallises from a warm solution in white scales. Nearly insol. water. Its ammoniacal solution deposits Ag on warming (Liebig a. Redtenbacher, A. 38, 132; Erdmann, J. pr. 25, 504).

—AgHA" (Perkin, C. J. 51, 369). Monoclinic

Ethylene-diamine salt C,H,O,(N,2H,C,H,). Dextrorotatory. Leaflets, v. sol. Water. The acid salt is sl. sol. water, S. 3 at 15°, and the solution is dextrorotatory (Colson, Bl. [3] 7, 808).

Mono-methyl ether MeHA". Formed by boiling tartaric acid with McOII (Guérin, A. 22,

boiling tartaric acid with McOII (Guérin, A. 22, 248). Prisms.—KMeA".—BaMe_A"_aq (Dumas a. Péligot, A. Ch. [2] 61, 200; [3] 5, 373).

Di-methyl ether Me_A". [48°]. (280° i.V.). S.G. (liquid) ½ 1°340. [a]_D = 2°454 at 18° (Anschütz a. Pictot, B. 13, 1176; 18, 1399); = 2°14 (Phillips a. Guye, C. R. 110, 714). Yields an acetyl derivative [103°] [a]_D = -14° and a dihenzoyl derivative [11]. = -88°8°.

benzoyl derivative $[a]_D = -88.8^\circ$.

benzoyl derivative [a]_D = -88°8°.

Mono-ethyl ether EtHA". [90°].
Formed by dissolving tartaric acid in boiling alcohol (G.; Marian, N. J. T. 13, 2, 43; Trommsdorff, N. J. T. 24, 1, 11; Guérin, A. Ch. [2] 62, 57]. Very deliquescent prisms.—NaEtA". Powder, sl. sol. alcohol (Mulder, B. 8, 370).—KETA". S. 106° at 23·5°. Colourless trimetric prisms; a:b:c=288:1: 417.—Cu(EtA'), 5aq.—Ba(EtA''), 2aq. S. 38 at 23°; 128 at 100°.—Pb(EtA''), —Cu(EtA''), 6aq. Blue silky efflorescent needles.—AgHA". Prisms.

Di-ethyl ether Et_Ah". (280° iV.); (233° cor. at 197 mm.). S.G. ½ 1:2097; ½ 1:2019. [a]_D = 9 at 18° (Anschütz a. Pictet, B. 13, 1176); 7:22 at 12°; 8:02 at 20° (Perkin, O. J. 51, 363). M.M. 8.766 at 14.8°. Liquid miscible with water (Demondesir, A. 80, 301). Sodium forms CO_Et.CH(ONa).CH(OH).CO_Et. the latter being converted by EtCl into a deposit and a

CO_Et.CH(ONa).CH(ONa).CO_Et, the latter being converted by EtCl into a deposit and a liquid, part of which is soluble in alcohol and which and part insoluble in alcohol and ether (Mulder, R. T. C. 8, 375; 9, 238; 10, 171; cf. Cohn, B. 20, 2003). The soluble product mixed with alcoholic CuCl₂ and poured into water forms a pp. crystallising in light-green needles, sol. alcohol and ether, insol. water and CuCisH2,O11. Tartaric ether is converted by treatment with gaseous HCyO into allophanyl-tartario ether NH₂,CO.NH.CO.O(C₄H₃Et₂O₅) [188°], which is m. sol. hot water and alcohol.

A cetyl derivative of the ether CO_Et.CH(OAc).CH(OH).CO_Et. Formed from the ether and AcCl, the mixture becoming hot (Perkin, C. J. 20, 145). Heavy oil, sl. sol. water, insol. saline solutions. Neutral to litmus.

Di-acetyl derivative of the ether CO_Et.CH(OAc).CH(OAc).CO_Et. [67°]. (292°) (Pictet, B. 14, 2790); (230° at 100 mm.). Formed by heating tartaric other with AcCl at 100° (Perkin;

by heating tarturation with Accitation (Ferali; Wislicenus, A. 129, 187). Prisms (from water), v. sl. sol. water. Slowly saponified by KOHAq. Acetyl-benzoyl derivative of the ether CO_Et.CH(OAc).CH(OBz).CO_Et. Formed by heating the mono-benzoyl derivative of the

Mono-benzoyl derivative of the ether CO_Et.CH(OH).CH(OBz).CO_Et. [647]. Formed by heating the ether with BzCl at 100°. Prisms, sl. sol. hot Aq. Saponified by alcoholic potash yielding C₂H₂(OII)(OBz)(CO₂Et).CO₂K, C₂H₂(OH)(OBz)(CO₂Et).CO₂K, and finally, potassium tartrate. C₂H₂(OH)(OBz)(CO₂Et).CO₂H forms tufts of needles, sl. sol. water.

Di-benzoyl derivative of the ether

[a]_D = -60° (Phillips a. Guye, C. R. 110, 716).

Di-n-propyl ether Pr₂A'. (303° i.V.),

S.G. 17 1·1392. [a]_D = 13·77 at 18° (A. a. P.);

= 12·44 (P. a. G.).

Di-isopropyl ether Pr₂A". (275°). S.G. 2º 1·130. [a]_D = 14·89 at 20° (Pictet, J. 1882,

20 1·130. $[a]_D = 1.00$. 856). Liquid. Di-isobutyl ether (Pr.CH₂)₂A". [68°]. (324°). S.G. 102 1·015. $[a]_D = 19\cdot9^\circ$ (P.).

(324°). S.G. 192 1-015. $[a]_D = 19.9^\circ$ (P.). Yields a dibenzoyl derivative $[a]_D = -42^\circ$. Isoamyl ether $(C_sH_{11})HA''$. Formed by digesting tartaric acid (150 pts.) with isoamyl alcohol (88 pts.) at 130° (Balard, A. Ch. [3] 12, 309; Breunlin, A. 91, 314). Nodular mass, with very bitter taste.— $KC_sH_{11}A''$ aq. Crystalline.—NaC_sH₁₁A''. Nodules. — Ba $(C_sH_{11}A'')_2$ 2aq: pearly plates (from water).—Pb $(C_sH_{11}A'')_2$ —Ca $(C_sH_{11}A'')_2$ —Ag $C_sH_{11}A''$. Tufts of needles. Di-acetul derivative $C_sH_{11}O_s$. 4.e.

Di-acetyl derivative $C_{H_10}O_g$ i.e. $CO_2H.CH(OAc).CH(OAc).CO_2H.$ [$a_{1p}=-23\cdot14$ (Phillips a. Guye, C. R. 110, 716). Formed slowly from the anhydride by the action of water. Hard deliquescent crystals (containing Saq), melting at 58°. V. sol. water, alcohol, and ether, sl. sol. benzene. Lævorotatory. Its salts form lævorotatory solutions (Colson, Bl. [3] 7, 806; C. R. 114, 417). Converted into tartario acid by hot KOHAq.—KHA": crystalline powder.— BaA": slender deliquescent needles.—CaA".—CuA".—Ag₂A": white crystalline mass.— Ethylene-diamine salt C,H,O,(N,H,C,H,).

Laworotatory. V. sol. water.

Anhydride of the di-acetyl derivative C₃H₃O₂, [127°]. Formed by heating tartaric acid with AcCl (Ballik, Sits. W. 29, 26; Pilz, Sits. W. 44 [2] 7; Perkin, C. J. 20, 149). Slender needles (from benzene). Dextrorota-

Benzoyl derivative C₁₁H₁₀O₇ i.e. CO₂H.CH(OH).CH(OBz).CO₂H. Formed UO2H.CH(OH).CH(OBz).CO2H. Formed by heating tartaric acid with benzoic acid at 150°

(Dessaignes, J. Ph. [3] 82, 47). Minute crystals, V. sol. water, sl. sol. alcohol.—Ag,A": white pp.
Di-benzoyl derivative C, H, O, i.e.
CO,H.CH(OBz).CH(OBz).CO,H. [90°].

[a] = -116° in alcohol. Formed by dissolving

its anhydride in hot water. Needles (containing aq). Converted by heat into a crystalline substance melting at 132°.

Anhydride C₁₈H₁₂O₇. [174°]. [a]_D = 143° in acctone at 18°. Formed by heating tartaric acid with BzCl. Small needles, insol. cold water, sol. alcohol, benzene, and alkalis. Dextro-

Di-nitroxyl-derivative

CO.H.CH(NO.).CH(NO.).CO.H. Nitrotartaric acid. Formed by dissolving tartaric acid (1 pt.) Nitrotartaric olume of H₂SO, (Dessaignes, A. 82, 362; 89, 339). The crystals are dried and crystallised from ether (Kekulé, A. 221, 245). Silky prisms, decomposed by hot water, forming oxalic and tartronic acids, CO., and NO. Alcohol containing IINO, forms di-oxy-tartaric acid. Ammonium sulphide reduces it to tartaric acid.— (NH.)HA''.—Ag A'' aq. V. sol. water.—Et₂A''. [46°]. S.G. ¹⁵ 1-278. Formed by dissolving tartaric ether in a mixture of HNO, and H.SO, and ppg. with water.

Amide C.H.O. (CC NH2). Formed by passing NH, into an alcoholic solution of the other, or of its di-acetyl derivative (Demondesir, A. 80, 303; Pasteur, C. R. 35, 176; Grote, A. 130, 202; Ruhemann, B. 20, 3366). Trimetric crystals (from water), v. c. sol. water. Dextrorota-

Amic acid C.H.NO. i.e. CO.H.CH(OH).CH(OH).CO.NH... Formed by passing NH3 over tartaric anhydride moistened with alcohol (Laurent, Compt. Chim. 1845, 153). with alcohol (Laurent, Compt. Ordin. 1843, 1845). Formed also, together with tartaric acid, by heating tartaric ether with NH, Aq at 100′ (Grote). Syrup. -CaN₂ 6aq: tetrahedra, v. sol. water.—Pb₁(C₄H, NO₂)...—BaN₂ 8aq.—EtA'.

Anilide C₂H₁O₂(CO.NHPh)... [250°].

Formed by boiling aniline with tartaric acid (Polikier, B. 24, 2959). Pearly scales, insol. water, sl. sol. other solvents. Yields mono-, di-, and tri-acetyl derivatives, melting at 227°, 216°,

and 137° respectively.

Phenyl-amic acid C₁₀H₁₁NO₅ i.e. CO₂H.CH(OH).CH(OH).CO.NHPh. Formed by boiling the phenylimide with NII3Aq (Arppe, A. 93, 352). Plates, v. sol. water and alcohol.—BaA'2: spangles, m. sol. hot water .-Agh': white powder, v. sl. sol. water.

Phenylimide C₁₀H₂NO₄ i.e.

CH(OH).CO NPh. [230°]. Formed, together

with the anilide, by heating tartaric acid with aniline at 150°. Pearly plates, v. sol. water. Di-o-toluide C₂H₁O₂(CO.NH.C.H.Me)... [183°]. White plates, insol. water (Bischoff, B. 23, 2049). Ac₂O at 140° yields a di-acetyl compound [222°].

Di-p-toluide C₂H₁O₂(CO.NH.C₄H₁Me)... [264*]. Got by heating p-toluidine with tartaric acid at 185°. Silky needles (from alcohol). Converted by Ac₂O into a di-acetyl derivative

Hydraside C₂H₂(OH)₂(CO.NH.NH₂)₃.

zine hydrate (Von Rothenburg, B. 26, 2057). Needles, sl. sol. alcohol. Converted by benzoic aldehyde into C.H. (OH) (CO.N.H:CHPh), [225°], crystallising in yellowish plates (from alcohol).

Lævo- tartario acid СО_Н.СН(ОН).СН(ОН).СО.Н. acid. [170°]. When a solution of racemic acid is divided into two equal parts and one is neutralised by animonia and the other by soda, and the solutions mixed and allowed to evaporate, hemihedral crystals of Na(NII,)C,H,O, are obtained. Half of these crystals have the hemihedral faces oppositely situated to those of the other half; and on carefully selecting the two kinds of crystals (the solutions of which exhibit equal and opposite action on polarised light), ppg. their solutions by lead nitrate, and decomposing the lead salts by H2S or H2SO40 solutions are obtained which on evaporation yield crystals, the one of dextro- and the other of lavo-tartaric acid (Pasteur, A. Ch. [3] 28, 56), If in a solutien of sodium ammonium racemate of S.G. 1.26 a crystal of the dextro- salt be put on one side and one of the lavo- salt be put on the other side of the vessel, the two salts will crystallise separately (Jungtleisch, J. 1h. [5] 5, 346). The separation of sodium ammonium racemate into the dextro- and lavo- tartrates does not take place if the solution is heated to 118° in a scaled tube and allowed to crystallise without access of air (Bichat, Bl. [2] 46, 54). According to Wyrouboff (C. R. 102, 627), the splitting up of the sodium ammonium racemate depends upon strength of solution and temperature only.

Laevo-tartaric acid is exactly like dextro tartaric acid in solubility and S.G. Its crystals are like the reflection of those of the dextroacid. The two acids are oppositely pyro-electric. Solutions of the layer acid exhibit an effect on light equal and opposite to that produced by solutions of the dextro- acid of like strength. When conc. solutions of equal quantities of the dextro- and levo- acids are mixed, heat is given out and racemic acid separates. The saits of the lavo-tartaric acid have the same amount of water of crystallisation, and the same crystalline form as the salts of dextro-tartaric acid. They exhibit opposite hemihedry, opposite rotation, and are oppositely pyro-electric. Differences are observed between the compounds of the two seids with optically active substances. Acid ammonium (active) malate combines with acid ammoniam dextro- (but not levo-) tartrate. Cinchonine levo- tartrate C, H2, N2OC, H2O, con-

tains aq, while the dextro-tartrate contains 4aq. Di-methyl-ether Me₂A''. [48°]. (160° at 16 mm.). Laworotatory (Anschütz, B. 18, 1398; A. 247, 112).

the di-Di-acetyl derivative of methyl ether CO2Me.CH(OAc).CH(OAc).CO,Me. $[a]_D = -1.3$ (in a 3.6 p.c. solution in alcohol of S.G. 826). Formed by heating Me₂A" with AcCl. Monoclinic plates (from benzene); a;b:c=1.052:1:1.007; $\beta=87^{\circ}$ 54'. On mixing with the corresponding dextro-compound it forms the isomeric racemic compound [86°].

Amide C₄H₄O₄(NH₂)₂. Combines with the amide of active malic acid, forming needles, S.

more than 33.

Racemie acid C.H.O. Paratartaric acid.

[2067] (Bischoff, B. 22, 1812). S.G. (of H₂A")

1 1.778; (of H₂A" aq) 1.687 (Perkin, C. J.

51, 366]. S. (of H₂A") 8.16 at 0°; 18 at 20°;

187-8 at 100°. S. (of H₂A" aq) 9.23 at 0°; 20·6

at 20°; 1849 at 100° (Liedie, C. R. 95, 87).

Heat of solution at 9°: −5675 (for H₂A");

−7065 (for H₂A" aq) (Pickering, C. J. 51, 367).

H.C. (for H₂A" aq) 278,400. Acid potassium racemate either occurs sometimes in crude argol, or is produced therefrom in the purification processes (Kestner; Jungfleisch, C. R. 85, 805). On crystallisation of cream of tartar, acid potassium racemate remains in the mother-liquor.

Constitution.—Assuming racemic acid to be a compound of the dextro- and levo-tarraric acids, its formula must be at least $(C_4\Pi_aO_a)_2$.

Formation.—1. By mixing solutions of dextro- and lawo- tartario acids.—2. By heating tartaric acid (30 g.) with wate (4 c.) for 30 hours at 175° (Jungfleisch, Bl. [2] 18, 203).—3. By heating the dextro- or lawo- tartrate of quinine or cinchonine at 170° (Pasteur, A. 72, 164; 84, 154; 88, 211).—4. By heating tartaric ether.—5. By heating inactive tartaric acid at 200° or by boiling it with HClAq (Dessaignes, Bl. 1865, i. 34).—6. By oxidation of fumaric acid by aqueous KMnO₄ (Kekulé a. Anschütz, B. 18, 2150; A. 226, 191; cf. Tanatar, B. 12, 2293).
7. By the action of HNO₄ on lawulose, mucic acid, and inulin; and, together with tartaric acid, by the action of HNO₄ on milk sugar, cans sugar, saccharic acid, dulcite, and mannite (Carlet, Rep. Chim. pure, 2, 345; 4, 17; Hornemann, J. pr. 89, 283).—8. Together with inactive tartaric acid by boiling silver di-bromo-succinate with water (Perkin a. Duppa, C. J. 13, 102; Pasteur, A. Suppl. 2, 242; Jungfleisch, Bl. [2] 19, 198).—9. By boiling silver iso-di-bromo-succinate with water (Demuth a. Meyer, B. 21, 268).
10. By boiling glyoxal with dilute HCy and HCl (Schöyen, A. 132, 168; Strecker, Z. [2] 4, 216).—11. By the action of zinc-dust (2 mols.) and dilute HOAc (3 mols.) on glyoxylic acid (1 mol.) at 100° (Genviesse, Bl. [3] 7, 225; C. R. 114, 555).—12. From piperic acid, sorbic acid, and CHO.CH.CH.CH.CH.CO₂H by careful oxidation with dilute KMnO₄ below 4° (Doebner, B. 23, 2374).—13. By heating a solution of desoxalic acid (Lowig, J. 1861, 605; Klein, J. pr. [2] 20,

Preparation.—Sodium ammonium racemate, got from the mother-liquor from which cream of tartar has separated, is treated exactly in the same way as cream of tartar in the preparation of tartaric acid. The small opaque needles of racemic acid can be separated by handpicking from the large, transparent crystals of tartaric acid.

Properties. — Triclinic crystals (containing aq); a:b:c=*484:1:806; $a=120^\circ$; $\beta=96^\circ$ 15'; $\gamma=76^\circ$ 5' (De la Provostaye, A. Ch. [3] 3, 131). Slightly efflorescent. Gives off aq at 100°. Less soluble than tartaric acid. In dilute solutions of racemic acid the lowering of the freezing-point is the same as with an equal weight of tartaric acid (Racult, Z. Ph. 2, 186). Absorption of a solution of racemic acid by filter paper does not separate the dextro- and lawo- acids (March-

lewski, B. 26, 988). A solution of gracemic acid is ppd. by CaSO₄ (unlike tartaric acid). Calcium racemate is insol. acetic acid (unlike calcium tartrate). NH₄Ol does not hinder the ppn. of calcium racemate. When heated above 200° racemic acid yields the same products as tartaric acid. By various ferments (e.g. Penicillium glaucum) racemic acid, when fres or as acid ammonium salt, is converted into tartaric acid (Pasteur; cf. E. Mulder, R. T. C. 1, 231). A solution in HNO₂ (S.G. 1-52) poured into half its volume of H.SO₄ deposits the crystalline C₂H₂(O.NO₂)₂(CO₂H)₂ (Dessaignes, J. Ph. [3] 32, 46). AcCl converts racemic acid into di-acetyl-racemic anhydride C₂H₂(OAO₂)₂C₂O₃ [123°]. Racemic acid and its salts are inactive to light.

Salts (Fresenius, A. 41, 1; 53, 230).—
(NH₄),A". Trimetric prisms; a:b:c=509:1::847.

Di-methyl ether Me,A". [85°]. (282°
i.V.). Formed by methylation of racemic acid, and also by mixing equal weights of the dimethyl ethers of the lawo. and dextro-tartaric acids (Anschütz a. Pictet, B. 13, 1178; 18, 1397; A. 247, 116). Monoclinic crystals; optically inactive. Yields a di-acetyl derivative C,H₂(OAc)₂(CO₂Me)₂ [86°] in trimetric crystals; abc = 8095:1: 6728. This compound, examined by Racult's method, has the same molecular weight as the di-acetyl derivative of di-methyl tartrate.

Mono-ethyl ether EtHA". Deliquescent prisms, v. sol. alcohol. Inactive to light.—KEtA" aq.—Ba(EtA"), 2aq.—AgEtA". Prisms.

Di-Bihyl ether Et.A". (238° cor. at 197 mm.) S.G. 15 1 2098; 35 1 2021. M.M. 8 759 at 15 5° (Perkin, C. J. 51, 364). Yields an oily acetyl derivative and a di-acetyl derivative C₂H₂(OAc)₂(CO₂Et)₂, [51°] (230° at 100 mm.). BzCl forms C₂H₂(OH)(OBz)(CO₂Et)₂, [57°]. The compound C₂H₂(OEt)₂(O₂Et)₂ (147° at 15 mm.) is formed from differential terms are considerable. [58°] and is formed from di-bromo-succinic ether [58°] and NaOEt (Michael, J. pr. [2] 46, 234). $\Lambda g_* \Lambda''$. AgHA". Monoclinic, a:b:c = 721:1: 869; β = 70°

Inactive tartaric acid GO,H.CH(OH).CH(OH).CO.H. Mesotartaric acid. [140°-143°]. S. 125 at 15°. Formation.—1.By heating cinchonine tartrate

or racemate for several hours at 170° (Pasteur, A. 88, 212). The product is mixed with CaCl., which ppts. calcium racemate, and the filtrate slowly deposits calcium inactive tartrate.—2. By boiling tartaric or racemic acid for 400 hours with HClAq (Dessaignes; Pasteur, Bl. 1862, 107).—3. By heating tartaric acid (30 g.) or racemic acid with water (4 c.c.) for 2 days at acid K salt Jungteisch, Bl. [2] 19, 101).—4. A product of the action of HNO, on sorbin (Dessaignes, C. R. 55, 769), erythrite (Przybytek, B. 17, 1412; Bl. [2] 43, 126) and glycerin.—5. By oxidation of levulose (Kiliani, B. 14, 2530).— 6. By oxidation of phenol by alkaline KMnO, at 0° (Doebner, B. 24, 1755).—7. A product of the action of moist Ag₂O on di-bromo-succinic acid. 8. By the action of nitrous acid on di-amidosuccinic acid (Lehrfeld, B. 14, 1819) .- 9. By oxidation of maleio acid by alkaline KMnO₄ (Kekulé a. Anschütz, B. 14, 713).

Properties.—Prisms (containing aq). Loses its aq at 100°; at 200° it yields pyrotartaric and racemic acids. Prolonged boiling with HClaq converts it into racemic acid (Dessaignes). The conversion is also effected by heating the acid with a little water at 175°. The ether is converted by AcCl into C₂H₂(OA₂)₂(CO₂Et)₂ [48°], crystallising in silky readles

needles.

Metatartaric acid (O,H₂O₃), A deliquescent,
glassy mass, v. sol. water, obtained by melting

tartaric acid (Braconnot, A. Ch. [2] 68, 299;

Erdmann, A. 21, 9; Laurent a. Gerhardt, A.

70, 848). It is sometimes formed when a

70, 848). It is sometimes formed when a solution of tartaric acid is evaporated over a water-bath (Grosjean, C. J. 43, 334). Converted by boiling water into tartaric acid.

Salts.—(NH,)HA". Minute needles. More

soluble than the acid ammonium tartrate. Its solution is ppd. by CaCl, and NH,Aq only when highly concentrated. CaA" 4aq. Minute lonticular grains, sol. dil. HClAq, converted by boiling water into calcium tartrate.

Ditartaric acid C.H.,O., An anhydride of tartaric acid, got by heating tartaric acid at 170° sariaric and, got by nearing saturation and still it is no longer ppd. by lime-water (Fremy, A. 19, 197; 29, 142; 78, 297). Amorphous and very deliquescent. Sol. alcohol, insol. ether. Its saits are amorphous, v. sol. water, and ppd.

by alcohol. They are converted into metaby accord. They are converted into meta-tartrates, and finally into tartrates, by boiling water.—CaA'.—BaA''.—PbA''.—OuA''.—Ag₂A''. V. sol. water (Schiff, A. 125, 129).

Ethyl ether Et.A". Fat-like solid.

Tartrelic acid QHO. Soluble tartaric anhydride. Formed by quickly heating small quantities of tartaric acid till the fused mass swellsup. Yellowish deliquescent mass, sol. water, forming an acid solution, from which CaCl. ppts. CaA'₂ as an amorphous mass, which becomes crystalline on adding alcohol. Tartrelic acid is converted into tartaric acid by boiling water.

Insoluble tartaric anhydride C.H.O. Formed by heating tartaric acid for some time at 150° and exhausting the product with cold water. Powder, insol. water, alcohol, and ether. Converted by hot water into tartaric acid.

TARTRONIC ACID Callio, i.e.

CH(OH)(CO,H),. Oxy-malonic acid. Mol. w. 120. [187°]. Neat of solution -4331 (Gal a. Werner, Bl. 12] 46, 803).

Formation. -1. By spontaneous decomposition of nitro-tartaric acid in aqueous solution (Dessaignes, C. R. 34, 731; 38, 442.—2. By the reduction of mesoxalic acid by sodium-amalgam (Raeyer, J. 1864, 641).—3. By the action of Ag,O on bromo-malonic acid (Petrieff, B. 11, 414).—4. By boiling chloro-malonic ether with KOHAq, the yield being 25 p.c. of the theoretical amount (Conrad a. Bischoff, A. 209, 222).— 5. From di-bromo-pyruvic acid and baryta-water at 40° (Grimaux, B. 10, 903).—6. From glyoxylic acid by treatment with KCy, the resulting nitrile being saponified (Böttinger, B. 14, 729) .- 7. A product of the action of alkaline cupric solution on glucose (Claus, Z. [2] 5, 152; A. 147, 114).—8. By slow oxidation of glycerin (Sadtler, B. 8, 1456; Campani a. Bizzari, G. 12, 1).--9. By heating sodium carboxy-tartronate • (Gruber, B. 12, 514).

Preparation.--1. By boiling the di-nitrate of

tartaric acid (20g.) with alcohol (60g. of S.G. 925) (Demole, B. 10, 1778).—2. By warming tri-chloro-lactic ether CCl₃.CH(OH).CO₂Et with a 10 p.c. solution of NaOHAq (5 mols.), neutralising with HOAc and ppg. with BaCl₂ (Pinner

B. 18, 752, 2852).

Properties.—Prisms (containing laq), v. sol. water and alcohol, sl. sol. other. After drying at 100° it loses its water of crystallisation and becomes v. sol. ether. Massol (C. R. 114, 422) obtained anhylrous crystals [155]. Decomposed by fusion, yielding CO2 and glycolide C2H2O2.

by fusion, yielding CO₂ and glycolide C₁H₂O₂. Reduced by HIAq to malonic acid.

Salts.—Na₂A" (dried at 100°). V. sol. water. — K₂A" a₄, — (NH₄)A". Needles. — *(NH₄)HA". Yields glycollic amide on heating.—BaA" 2aq. Micro-crystalline powder, v. sl. sol. water (Pinner).—BaA" aq (G.).—CaA" 2aq (C. a. B.).—CdA".—PbA" (dried at 120°).—MnA".—Ag₂A". Needles (from hot Aq). Ethyl ether Et,A". (c. 224°). Heavy oil (Freund, B. 17, 786; Pinner).

The acetyl derivative CH(OAc)(OCEt).

The acetyl derivative CH(OAc)(CO,Et)₂ (c. 161° at 60 mm.), S.G. $\frac{12.6}{16}$ 1·131, is formed from bromo-malonic ether and KOAc in EtOH at 50° (Conrad a. Brückner, B. 24, 2997). Br converts it into mesoxalic ether C(OH)₂(CO₂Et)₂

Amide CH(OH)(CO.NH2)r. [196°]. Six-

sided plates, m. sol. hot water.

Amic acid CO.H.CH(OH).CO.NH, [160°]. Formed by boiling sodium dialurate with water Menschutkin, A. 182, 82). Needles, sl. sol. cold water. Converted by nitrous acid into glycollic acid.—KA'aq.—BaA', aq.—PbA', ½aq. Needles, v. sol. hot water.—AgA'. Needles.

Phenyl derivative CH(OPh)(CO₂H).

Formed by saponification of its ether CH(OPh)(CO₂Et)₂ (230°-240° at 60 mm.), which is got from bromo-malonic ether, phenol, and NaOEt (C. a. B.). At 196° it forms NaOEt (C. a. B.). CH₂(OPh).CO.H.

TARTRONYL-UREA v. DIALURIO ACID.

TAURINE C.H, NSO, i.c.

CH,(NH,).CH,SO,H. Amido-ethane sulphonic acid. Mol. w. 125. S. 6.5 at 12°. H.F. 185,700 (Berthelot a. Matignon, A. Ch. [6] 22, 182). Obtained by the action of acids and alkalis on taurocholic acid (Gmelin, Ticdemann a. Gmelin's Die Verdauung, 1, 43; Domarcay, A. 27, 286; Dumas a. Polouze, A. 27, 292; Redtenbacher, A. 57, 170; Strecker, A. 65, 132; 67, 34; 91, 101). Occurs in the free state in putrid bile and in the muscles of the oyster, in shark's blood, in the liver, spleen, and kidneys of the ray, and in the lungs of oxen (Valenciennes a. Fremy, C. R. 41, 735; Städeler a. Frerichs; Clöetta, A. 99, 289). Formed also by heating B-chloro-ethane sulphonic acid with NH, Aq at 100° (Kolbe, A. 122, 33), and by the action of SO₂ on yinylamine (Gabriel, B. 21, 2667). Prepared by evaporating ox bile with dilute HCl at 100°, decanting from a resin, allowing to crystallise, and re-crystallising from water. It may be purified by means of the lead sait.

Properties. -Transparent crystals, m. sol. water, insol. alcohol. Neutral to litmus. Not melted below 240°. Converted by nitrous acid into isethionic acid (Gibbs, Am. S. [2] 25, 30).

Decomposed by potash-fusion.

Salts.—NaA'. Very deliquescent (Lang, Bl. [2] 25, 180).—CaA'₂. Slender noedles, v. o. sol. water.—PbA'₄. Needles, v. c. sol. water.—PbA'₄(OH)₂—CdA'₂.—HgA'₂—HgA'₂O (Engel, Bl. 190) 25 529). AGA'₂. Pb,A',(OH), -CdA', -11 Bl. [2] 23, 532).—AgA'.

Benzoyl derivative NHBz.C.H.SO,H. Formed by heating μ -phenyl-thiazole tetrahy-dride with HCl and bromine-water (Gabriel a. Heymann, B. 23, 159). Syrup.-AgA'. Spherical groups of plates.

Phthalyl derivative
(C₈H₄O₂):N.CH₂.CH₂.SO₃H.

Got by oxidising di-phthalimido-di-ethyl-disulphide with IINO, (S.G. 1·25) (Gabriel, B. 24, 1116). Crystals (containing 1] aq.), sol. EtOAo₁. Tastes bitter.

Imide C₂H (NH SO.) [45°-50°]. Prepared 8 - chloro - ethane - sulphonic chloride CH, Cl. CH, SO Cl by treatment with ammonia (James, C. J. 49, 491). Solid, resembling gum arabic; bitter in taste. V. sl. sol. cold, v. sol. hot, water, insol. alcohol and ether. Ppd. HgO appears to form the compound (C₂H₄SO₂N)₂Hg.

Ethyl-taurine v. ETHYL-AMIDO-ETHANE SUL-PHONIC ACID.

Methyl-taurine v. METHYL-AMIDO-ETHANE AULPHONIC ACID.

TAUROCHENOCHOLIC ACID C, H, NSO, Occurs as K and Na salts in goose-bile (Heintz

a. Wislicenus, P. 108, 547; Otto, A. 149, 192). Amorphous, sol. water and alcohol. Decomposed by boiling with baryta or potash into taurine and chenocholic acid.—NaA'aq (dried at 110°). Small tables. Its aqueous solution gives pps. with CaCl₂, AgNO₃, and lead subacetate, but not with lead acetate.

TAUROCHOLIC ACID C., H, NSO, Occurs as Na salt in the bile of most animals (Strecker, A. 67, 30; 70, 169; Hüfner, J. pr. [2] 19, 302; Copeman a. Winston, J. Physiol. 10, 213). Obtained by ppg. with lead acetate, filtering from lead glycocholate, and ppg. lead taurocholate by lead subacetate. Deliquescent silky needles, v. sol. water and alcohol, m. sol. ether. Dextrorotatory, [a]_b = 25° (Hoppe-Seyler, Arch. Path. Anat. 15, 126). Boiling water splits it up into taurine and cholic acid. Antiseptic, and ppts. albumen completely from its solutions (Maly, M. 4, 89). Salts.—NaA' (dried at 120°). Ppd. by alco-

hol in an amorphous state, rendered crystalline by ether. -- KA'. Needles, resembling wavellite. TAUROCYAMINE C,H,N,SO, i.c. NH:C(NH,),NH.CH,.CH,.SO,H. [226°]. S. 4 at 21°. Formed by heating taurine with cyan-

amide (1 mol.) and water at 110° (Engel, B. 8, 1597; Dittrich, J. pr. [2] 18, 63). Small white prisms, v. sol. water, insol. alcohol and ether. From cold water it crystallises with aq.

TAXINE C_a, H₂NO₁₀. [82°]. Obtained from the leaves, twigs, and fruit of the yew (Taxus baccata) by extracting with ether (Lucas, Ar. Ph. [2] 85, 145; Van der Harst, R. T. C. 3, 279; Marmé, Bl. [2] 26, 417; Hilger a. Brande, B. 23, 464). The ethereal solution is quickly shaken with acidulated water, and the solution ppd. by NH,Aq. Crystalline. Gives off aromatic fumes on melting. V. sl. sol. water, v. sol. alcohol and ether, insol, benzene. Conc. H.SO, gives a deep purple : Fröhde's reagent a reddish-violet colour. Gives yellow pps. with sodium phosphomolyb-date, I in KI, and potassium bismuth iodide. Insol. alkalis. The salts crystallise with difficulty.—Salts: B'HCl.—B',HLSO,—B',HLPtCl. -B'HAuCl,.-B'EtI.

TECTOQUINONE. [171°]. Obtained from teak resin or by the distillation of teak wood (Romanis, C. J. Proc. 4, 116). Amber-yellow crystals, sol. alcohol. Reduced by zinc-dust and HOAc to C₁₈H₂₂. Yields a nitro-derivative and

a bromo-derivative [165°].

Salts of telluric acid, TELLURATES. TELLURIES.
Salts of telluric sold,
H_TeO_4(q.v., p. 649). The normal tellurates of
monovalent metals have the composition
M_TeO_4xH_O; there are also acid tellurates
MHTeO_4xH_O; and two classes of tetratellurates, (1) M_Te_O_1xH_O, which are soluble in
water when M is an alkali metal, and (2) M.Te,O13, which are insoluble in water. The hydrated tetratellurates may be represented as acid ditellurates derived from the hypothetical acid H.Te.O.; thus K.Te.O.; 4H.O. = 2KHTe.O., 3H.O. Some acid salts may be represented as derived from hypothetical ditelluric acid, e.g.

PbTe₁O₂ (= PbTeO₂.TeO₃).
The normal alkali tellurates are obtained by saturating H.TeO, with MOHAq or M2CO3Aq and crystallising. Alkali acid tellurates, and hydrated tetratellurates, are obtained by interactions of acids with the normal tellurates; anhydrous (insoluble) tetratellurates of the alkali

metals are formed by heating the acid tellurates: thus 6KHTeO₄ = K₂Te₄O₁₅ + 2K₂TeO₄ + 3H₂O.

Most of the other tellurates are obtained from the alkali salts by double decomposition.

The alkali tellurates, other than those of the form M.Te,O₁₃, are soluble in water; most of the other tellurates are insoluble or sparingly soluble in water. Tellurates generally dissolve easily in HClAq: the solutions are not ppd. by water, but on boiling the solutions become yellow, give out on boning the solutions become yellow, give off Cl, and then yield a pp. of H,TeO, on addition of water. Acidulated solutions of tellurates are slowly decomposed by H,S, probably with ppn. of ToS, (c. Tellurates are slowly reduced by SO, lutions of tellurates are slowly reduced by SO, more quickly on heating, with separation of Te. When tellurates are heated to redness they give off O and form tellurites; heated with K₂CO₃ and charcoal, they give K₂Te.

The tellurates have been examined chiefly

The tellurates have been examined chiefly by Berzelius (P. 32, 577); and some of them also by Oppenheim (J. pr. 71, 267).

Potassium tellurates. The normal salt K,TeO, 5aq is obtained by dissolving H,TeO, and K,CO, in the ratio H,TeO, K,CO, in hot water and crystallising; also by dissolving H.TeO, in excess of KOHAq, heating, and al lowing to cool slowly. Crystallises in rhombic prisms, isomorphous with K.SO, (Handl, J. 1861. 266). The crystals become moist in air and form K1HTeO, 2aq and K2CO. The acid salt 2KHTeO, 3aq separates on adding to K2TeO, Aq sufficient H2SO, Aq, or other strong acid, to remove half the potassium; the salt is crystallised from hot water. This salt is slightly soluble in cold water, but much more soluble in hot water; when heated it is converted into K₂TeO₄ and K₁Te₁O₁₃. The tetrat-flurate K₂Te₂O₁₃ is obtained, as a yellow powder, by heating 2KHTeO₄. Baq below redness and washing out K₂TeO₁ in water. K₁Te₂O₁₃ is insoluble in water, also in HClAq or HNO₃Aq except after prolonged boiling. The hydrated tetratellurate K₂Te₄O₁₃4H₂O--which may also be regarded as an acid ditellurate 2KHTe₂O₁3H₂O - isformed by adding H2SO, Aq, or another strong formed by adding Π_2 : G_1 : Aq in quantity to remove 6K from $4K_1$: TeO_1 , Aq in quantity to remove 6K from $4K_2$: TeO_1 , $4K_2$: TeO_1 , $Aq + 3H_2$: SO_1 , Aq = K_2 : Te_1O_1 , $Aq + 3H_2$: O_1 : Aq + $3H_2$: O_1 : O_1 : O_1 : O_1 : O_2 : O_2 : O_2 : O_3 is partly decomposed to KHTeO, and H.TeO, Aq by repeatedly crystallising in aqueous solution.

The following tellurates have been described (Berzelius, l.c.; Oppenheim, l.c.): Animonium salts (NH₁)₂Te₀, (NH₄)₂Te₂O₁, obtained by ppg. solutions of the corresponding salts of K or Na with NH.Cl. Barium salts ppn. Calcium salt CaTeO, obtained by ppn. Calcium salt CaTeO, obtained by ppn. Calcium salt CaTeO, obtained by ppn. Lead salts PbTeO, PbTeO, PbTeO, pbTeO, bp ppn; a basic salt is also said to exist. Silver salts Ag.TeO., and several basic salts xAg.O.yTeO., Sodium salts Na.TeO.xaq, NaHTeO.xaq, NaHTeO.xaq, NaHTeO.xaq, and Na.Te.O., to obtained similarly to the potassium salts. Tellurates of Al. larly to the potassium salts. Tellurates of Al, Cr, Co, Cu, Fe, Li, Mg, Mn, Hg, Ni, and Sr have also been described, but only very superficially. M. M. P. M.

TELLURHYDRIC ACID H.Te; v. Hydrogen TELLURIDE, vol. ii. p. 727.

TELLURIC ACID H.TeO.; crystallises from

Formation.—1. By oxidising Te by aqua regia.—2. K.TeO, is formed by the interaction of Cl with K.TeO, Aq, also by fusing TeO, with K.TeO, and the control of Cl with K.TeO, and the control of Cl with K.TeO, Aq, also by fusing TeO, with K.TeO, and K.TeO, Aq, also by fusing TeO, with K.TeO, and K.TeO, Aq, also by fusing TeO, with K.TeO, and K.TeO, Aq, also by fusing TeO, with K.TeO, Aq, also by fusing TeO, also by fus KNO, or KClO.

Preparation.—1. A mixture of TeO, KClO, and KOH, in the ratio TeO, 2KClO, 2KOH is thoroughly fused; the fused mass is dissolved in water and BaCl Aq is added; the pp. of BaTeO. is purified by recrystallisation from hot water, and is then dried at 100°; the dry BaTeO, is mixed with its own weight of water and one-fourth its weight of cone. H SO, and heated till decomposition is complete, when BaSO, is removed by filtration, and the filtrate is evaporated at 100° to the crystallising point; the crystals that separate are dried, powdered, washed repeatedly with alcohol to remove H.SO, and recrystallised from water (Oppenhein, J. pr. 71, 267). Berzelius (P. 28, 392; 32, 1) fused TeO₂ with an equal weight of KaCO₃ or Na CO₂, dissolved in water, added KOH equal to the weight of TeO₂ used, passed in Cl until the liquid smelt strongly thereof, ppd. by BaCl_Aq, and proceeded as described above.—2. TeO₂ is dissolved in HNO₃Aq, the solution is boiled with PbO₂ and filtered, Pb is ppd. from the filtrate by H.SO,Aq, the filtrate from PbSO, is evaporated to dryness at 100', the residue is digested with alcohol and ether to remove H.SO₄, and is then crystallised from hot water in vacuo (Becker, A. 180.

Properties and Reactions. - H, TeO, 2H,O is obtained by slow crystallisation in white, monoobtained by slow crystallisation in white, monocinic crystals, resembling gypsum, S G. 2-9999 at 25.5° (Clarke, Am. S. [3] 16,401). When obtained by rapid evaporation H. TeO, 2H. O appears as a glassy solid. Heated to c. 130° H. TeO, is obtained; decomposition begins at a little above 160° to TeO, and H.O, and at c. 180° TeO, begins to decompose to TeO, and O, this decomposition being complete at c. 350° (Wills. decomposition being complete at c. 350° (Wills, C. J. 35, 704). H.TeO, has S.G. 3·425 at 18·8° (Clarke, l.c.). H.TeO, 2H.O is slightly soluble cold water; it is dissolved fairly easily by boiling water; soluble in acid and alkali solutions; almost, if not quite, insoluble in alcohol. H.TeO, dissolves very slowly in boiling water. Aqueous solutions of H.TeO, have a metallic, Aqueous solutions of H₁TO₄, have a metallo, not a sour, taste; they very slightly redden litmus. Thomsen (Th. 2, 277) gives the following H.F.: [Te,O',Aq] = 98,380; [TeO'4Q,O] = 21,200. H.TeO₄ dissolves gradually in hot, fairly conc. HClAq, with evolution of Ol and formation of H₂TeO₄Aq. H₂TeO₄Aq is not reduced by passing H.S. into it, but if the solution is saturated with HS and kept in a warm tion is saturated with H.S and kept in a warm place, in a closed flask, for some time, the liquid becomes brown, and flakes, probably of TeS, (v.

TELLURIDES. Any compound of Te with a

single element more positive than itself is called a telluride. Tellurides of the heavier metals are generally formed by melting the metals with Te, also by passing H.Te into solutions of salts of the metals; tellurides of K and Na are formed

by heating TeO, with K2CO, or Na2CO, and charcoal; many tellurites and tellurates give tellurides when heated in a current of H. ppts. tellurides of Cu, Ag, and some other metals, by boiling solutions of salts of these metals with Te (Parkmann, C. C. 1862, 814). Tellurides of K and Na dissolve in water with a red colour; this colour is due either to polytellurides or to the presence of traces of oxides according to Demarçay (Bl. [2] 40, 99). Berthelot a. Fabre (C. R. 105, 92) obtained colourless solutions of (C. R. 105, 92) obtained colourless solutions of alkali tellurides by passing pure H₂Te into solutions of alkalis; a trace of O produced a red colour and separated Te. Tellurides react with HClAq giving off H₂Te; they are oxidised to tellurites by HNO₂Aq, and to tellurites and tellurates by agua regia. Warmed in Cl tellurides give metallic chlorides and TeCl₁.

Tellurides of Sb, As, Bi, Au, Fe, K, Ag, and Na are mentioned under these metals (cf. Brauner, C. J. 55, 388).

M. M. P. M.

Brauner, C. J. 55, 388). M. M. P. M. TELLURITES. Salts of tellurous acid

H₂TeO₃ (q. v., p. 656). The normal and acid tellurites of monovalent metals belong to the forms M, TeO, and MHTeO,. Some salts are also known containing relatively more of the acidic radicle; these may be formulated as $M_2O.x$ TeO₂ where x is 2 and 4; or they may be regarded as M.TeO₂.xTeO₂, where x is 1 and 3; or finally these hyperacid salts may be looked on as M₂Te₂O₅ and M₂Te₄O₉—that is, as derivatives of the hypothetical acids H₂Te₂O₅

Tellufrites are generally formed by heating together basic oxides and TeO, in the proper proportions; some tellurites of the heavier metals are obtained by ppn. from solutions of alkali tellurites. Tellurites of the alkali metals dis-solve readily in water; those of the alkaline earth metals are less soluble; the others are insoluble in water. Most tellurites dissolve in HClAq, forming yellow solutions which do not give off Cl on heating; this reaction distinguishes them from tellurates (v. p. 649). Solutions of tellurites in a little HClAq deposit H₂TeO₃ on dilution. Most tellurites are fusible, and crystallise on cooling; the hyperacid alkali tellurites form colourless glass-like solids after fusion. By strongly heating with charcoal and K₂CO₃ most tellurites give K₂Te.

Tellurites of potassium. The normal salt K,TeO, and the acid salt K,TeO, TeO. R_1eO₃, and the acta sate R₂1eO₃.1eO₂ (= K_TO₂O₃ or K_0.2TeO₂) are prepared by fusing TeO₄ with K₂CO₃ in the propex proportions. K₂TeO₃ melts at a red heat; dissolves slowly in cold water, more quickly in boiling water; the aqueous solution has an alkaline taste and reaction, and is decomposed by the CO_2 in the air. $K_2O.2TeO_3$ melts below redness, and solidifies again to a transparent, colourless, crystalline mass; dissolved by boiling water, and the solumass; dissolved by boiling water, and the solution on cooling deposits K_0.4TeO... The tetratellurite or hyperacid tellurite K_0.4TeO._4H_0 (= K_TeO_8TeO_4H_0 or K_Te_O_4H_0) is prepared by boiling H_sTeO_4A with K_CO. and filtering at 100°; the salt is deposited on cooling in microscopic six-sided prisms and tablets. This salt reacts with cold water to give a solution of K_TeO_4 and K_TeO_4 and a gelatinous pp. of H_TeO_5; when heated 4H_0 is given off, and K_0.4TeO_5 remains as a salt which melts at a

moderate red heat and solidifies on cooling to a colourless glass.

The tellurites have been examined chiefly by Berzelius (P. 32, 577; v. also Oppenheim, J. pr. 71, 267). Salts of the following metals have been isolated, but many have been studied in a very superficial way: Al, NH, Ba, Cd, Ca, Cr, Co, Cu, Fe, Pb, Li, Mg, Mn, Hg, Ni, Ag, Na, Sr, and Zn. M. M. P. M.

TELLURIUM. Te. At. w. c. 125 (v. infra). Mol. w. c. 250 (v. infra). Melts at c. 455° (Carnelley a. Williams, C. J. 37, 125). Boils at c. 1390° (Deville a. Troost, C. R. 91, 83). S.G. 6.2549 at 0° (after compression); 6.2322 at 0° organ at o' (after compression); 0'2522 at o' (uncompressed) (Spring, B. B. 5, 854); 6'2549 at 18'20' (after melting in H) (Přiwoznik, C. C. 1892. ii. 962; for further data v. Clarke's Table of Specific Gravities [2nd ed.] 10). V.D. at c. 1390' to c. 1440° = 130 (Deville a. Troost, C. R. 56, 891). to 6. 1440 = 130 (Devine a. 11008.) (1450, 50.) S.H. (21° to 51°, crystalline) '0475 (Kopp, T. 1865. 71); (at 98°, crystalline) '0483; (at 98°, after distillation in SO.) '0518 (Fabre, A. Ch. [6]) 14, 101). C.E. (linear, at 0°) 00001675 (Fizeau, C. R. 68, 1125). E.C. 000777 at 19-6 (Ag at 0° = 100) (Matthiesen, P. 103, 428); conductivity increases slightly when light falls on Te; the increase is very much less than in the case of Se (v. Adams a. Day, Pr. 24, 163; 25, 113). E.C. decreases slightly to o. 100°-140°, and F.G. increases to 200°; on cooling after fusion E.C. decreases regularly and markedly; the following values are given by Exner (P. 158, 625) .0035 at 200°, .00286 at 20° (after fusion), .000435 at 20° (after very slow cooling from fusion). crystallises in rhombohedra; a:c=1:1·3298; it is isomorphous with S and Se (v. Muthmann, Z. P. C. 8, 396). For emission-spectrum v. Plücker a. Hittorf (Pr. 13, 153); Thalen; Salet (A. Ch. [4]28,51); Ditte (C. R. 73, 622); Hartley a. Adency (T. 1884 [1] 117). For absorption-spectrum of vapour of Te v. Gernez (C. R. 74, 1190). H.C. $[Te,O^3,Aq] = 98,380 \ (Th. 2, 278)$.

Historical.—Examining a mineral containing gold from the Seven Mountains in 1782 Müller von Reichenstein suspected the presence of a new metal (Abhand. ciner Privatgesellschaft in Böhmen). He sent a specimen of the mineral to Bergmann, who said that it contained a metal which was not the same as that in blende. In 1798 Klaproth received some of the mineral from M. von R., and isolated the characteristic element, to which he gave the name tellurium (from tellus = the earth) (K., Beiträge zur chem. Kenntniss der Mineralkürper, 3, 1; cf. Crell's Ann. 1798, 91; and G. A. 12, 246). The compounds of Te were more fully examined by Berzelius (S. 6, 311; 34, 78; P. 8, 411; 28, 392; 32, 1,

Occurrence .-- Te is found native, in small quantities, and in a few localities-chiefly in Hungary and Transylvania, and in Virginia, U.S.; it generally accompanies Au and Ag; specimens have been obtained with 97-98 p.c. Te. Tellurides are also found in small quantities in Hungary, Mexico, California, Bolivia, and some other places; in considerable quantities in Colorado; these are generally compounds of Te with Bi, Ag, Pb, Bi and S, Ag and Au, Au, Pb and Sb; tellurite (or tellurium-cohre) containing TeO, is found in small quantities in the Seven Mountains (v. G. Bose, P. 18,64; Rammelsberg, J. M. 1874. 30; Burkart,
 J. M. 1873. 476; Silliman a. Marvine, Am. S. [3] 8, 25; Mathewson, J. M. 1866. 93; Genth.

Sales of the second

Loj o, 20; manewson, J. M. 1866. 98; Genth, J. M. 1875. 188, 314).

Fornation.—1. By passing SO₂ into H. TeO₂Aq;

H. TeO₂Aq + 2SO₂ + H. O = 2H. SO₄Aq + Te. Also by ppg. solution of TeCl. in dilute HClAq, or of a by ppg. solution of TeU, in dilute HClAq, or or a Te compound in H₂SO₄Aq, by an alkali sulphite. 2. By reducing a boiling solution of (NH₄)₂TeO₄Aq by grape sugar (Stolba, J. 1873. 214).—3. By decomposing K₂TeAq by air or oxygen (v. Oppenheim, J. pr. 71, 267; 81, 308; Himly, J. 1877. 213).—4. By ppn., by means of zinc, from solutions of Te compounds in H₂SO₄Aq (v. Löwe, J. pp. 60, 162). J. pr. 60, 163).

Preparation .- There are several methods of preparing crude To from the minerals that contain it. Native bismuth telluride is made into a paste with oil and K₂CO₃, and gradually heated to whiteness in a covered crucible; K₂Te is extracted from the fused mass by boiling water, and the solution deposits Te on standing in air. Or the mineral containing To is powdered and treated with dilute HClAq; the insoluble matter is gradually added to three times its weight of conc. H,SO,, and heating is continued until SO2 ceases to be given off; the solid that forms on cooling is dissolved in water containing a little HCl; the solution is filtered from AgCl, Te is ppd. from the filtrate by zinc, and undissolved zino is removed by digestion with dilute HClAq. For details and other methods v. Berzelius (P. 8,411; 28,392); Löwe (J. pr. 60, 163); Wöhler (A. 84,69); Oppenheim (J. pr. 81,308); Schmitzer (D. P. J. 211, 484, 492); Schwarz (D. P. J. 186,

29).
To prepare pure Te, Brauner (C. J. 55, 382; cf. M. 10, 411) recommends to digest the crude material with HClAq in a large flask, and to oxidise by HNO, Aq added little by little till the solid matter becomes white, to evaporate several times with conc. HClAq (to remove HNO,), and then to dilute cautiously with water, taking care not to add enough water to ppt. H2TeO, along with any PbCl, which may come down. He then adds some saturated SO₂Aq, warms to 60°-70°, and ppts. Te by passing SO₂ into the warm solution. The Te thus obtained generally contains a little copper and lead selenides. The pp. is dried and fused in small portions with KCy; the fused mass, which contains K2Te, is dissolved in water, from which air has been removed, in a stoppered flask; the liquid is allowed to clear (there is generally a small pp. of tellurides of heavy metals mixed with a trace of Te) and is then poured off, and a current of air is passed through it, whereby Te is ppd. The Te is dried, placed in a porcelain boat, which is introduced into a wide tube of hard glass surrounded by wire gauze, and distilled in a current of pure dry H. (For a method of purification based on the ppn of Te from (NH₄)₂TeO₄Aq by grape sugar, v. Stolba, J. 1878. 214.)

Properties.—As prepared by stalline, very H, tellurium is a white, shining, crystalline, white, crystalline, Properties .- As prepared by sublimation in brittle solid, unchanged by exposure to air. During distillation in H, Brauner (l.c.) noticed that some H.Te was formed, and was decomposed with deposition of needle-shaped crystals of Te, some of which were 1 centim. in length. The arystals of Te are hexagonal rhombohedra, iso-

morphous with S and Se (v. Muthmann, Z. P. O. 8, 396). By allowing K. TeAq to decompose in air, H. Rose obtained six-sided prisms with rhombohedral summits (P.21, 443; cf. Fabre a. Berthelot, C. R. 104, 1405). Amorphous Te is obtained as a brown powder by ppg. H. TeO, Aq by SO; on warming, the amorphous variety changes to the crystalline, giving off a large quantity of heat (F. a. B., I.c.). To that has been melted and cooled quickly seems to contain both the crystalline and the amorphous varieties. According to Fabre (A. Ch. [6] 14, 100), both varieties have practically the same S.H. at c. 100°. Te melts at c. 455° and boils at c. 1390°; the vapour is golden yellow. Heated in air it burns with a brilliant blue-green flame to white clouds of TeO2, which are poisonous; the smell, like that of decaying radishes, that is noticed on burning impure Te is due to the oxidation products of So, which is commonly present in specimens of crude Te. Te dissolves in very cone. boiling KOHAq, forming a red liquid that contains K₂TeO₃ and K₂Te; on allowing to cool, or on adding water, the whole of the Te separates. HClAq is without action on Te; cone. hot H₂SO₂ dissolves it slightly, but the Te cone. not H₂SO₄ dissolves it slightly, but the Te separates on dilution; when heated strongly with cone. H₂SO₄ To dissolves to H₂TeO₅ with evolution of SO₂. Te dissolves in SO₅, forming TeSO₅. Cone. HNO₂Ad forms a solution of H₂TeO₄; aqua regia forms H₂TeO₅, and some H₂TeO₅. Molton KNO₂ produces K₂TeO₅.

In its physical properties Te approaches the

In its physical properties Te approaches the metals, and especially resembles S5. In its chemical properties To is, on the whole, non-metallic; but the oxide TeO₂ combines with certain anhydrides of strong acids to form saltlike compounds, and the oxide TeO is said to dissolve in H2SO, Aq, forming Te(SO,)2. Te is closely related to Se, and less closely to S; it shows distinct analogies with Cr, Mo, W, and U (v. Oxygen group of elements, vol. iii. p. 705, and Chromium group of Elements, vol. ii. p. 168). The atom of Te is divalent in the gaseous molecules TeH, and TeCl., and tetravalent in

the gaseous molecule TeCl

Atomic weight of tellurium. The at. w. of Te was determined by Berzelius in 1812, 1818, and 1832 by oxidising Te by HNO₃Aq and weighing the TeO₂ produced; he obtained values varying from 1279 to 1285 (P. 8, 24; 28, 395; 32, 16). In 1857 von Hauer analysed K2TeBr. and obtained values from 126.5 to 128.1 (W. A. B. 25, 135). In 1879 Wills determined the weight of TeO, obtained by oxidising Te by HNO, Aq and by aqua regia, and he also made analyses of K, TeBro; his results varied from 126·1 to 129·3 (C. J. 35, 704). In 1883 Brauner obtained numbers varying from 124 94 to 125 4, by oxidising Te to TeO2, by converting Te and TeO, into (TeO₂), SO₃, and by synthesising Cu, Te (J. R. 1883. [1] 433; abstract in B. 16, 3055). In 1889 Brauner made a very careful revision of the at. w. of Te (C. J. 55, 382):—(i.) by oxidising Te to TeO₂ he obtained values varying from 124.48 to 127.28; (ii.) by converting TeO, into (TeO₂₎₂SO₂, the numbers varied from 124.7 to 129 (one result gave 135-9); (iii.) by conversion of Te into (TeO₂)₂SO₃, the numbers varied from 124-3 to 129-7; (iv.) by syntheses of tellurides of Ag, Cu, and Au, the numbers varied from 125.7

to 129.9; (v.) by analysis of TeO₂ the value 127.2 was obtained, but only one satisfactory analysis was made; (vi.) by analyses of TeBr, the numbers varied from 127.27 to 127.31. The results obtained by analysing TeBr, were more concordant than any obtained by the other methods; but the value 127.3 is almost 75 units greater than the at. w. of iodine; hence it seems as if the at. w. of Te is greater than that of I. But if this is so, Te must be separated from S, Se, and the chromium metals, which are placed in Group VI. in the periodic arrangement of the elements; and Te must be placed either with the halogens in Group VII. (I being put into Group VI.), or this element must find a place in Group VIII. (I remaining in Group VII., and an empty place being left in Group VII., Series 7). The chemical properties of Te show that it belongs to the same group as S and Se; and the chemical properties of I make it impossible to place that element elsewhere than with F, Cl, and Br.

Is tellurium a homogeneous body? Rather than doubt the applicability of the periodic law, Brauner made the hypothesis that tellurium is not a homogeneous body, but that it contains an admixture of foreign substances. He dissolved Te, and ppd. in fractions by SO₂, fused the fractions with KCy, dissolved in water, and ppd. fractionally by a current of air; he then distilled each fraction in II, and converted it into TeBr., and analysed each fraction. The values thus obtained for the at. w. of Te were almost identical, the mean being 127-33. Pure TeO. was then dissolved in HClAq, and the solution was ppd. in eight fractions by ammonia; the filtrate from the eighth fraction was ppd. by SO. in presence of HClAq; after boiling off SO, from the filtrate from the ninth fraction, the liquid was saturated with H2S, and the TeO2 in solution was obtained, converted into Te, and this converted into TeBr₄; the at. w. thus obtained (in three experiments) was 127.32, the three experiments agreeing extremely well. Te was then fused, but not distilled, in a current of H; it was then converted into TeBr,, which was freed from TeBr., by fractional sublimation in vacuo, without converting the TeBr, into vapour, and analysed; the values obtained for the at. w. of Te differed very much, ranging from 128.5 to 137.4. From these results Brauner concluded that 'if tellurium, obtained by any process of fractionation whatever, be subjected to distillation in a current of hydrogen, and the tetrabromide be prepared from this by sublimation in a vacuum, its analysis always gives the same atomic weight for tellurium. . . . If, however, the tellurium be only fused in a current of an indifferent gas, and the tetrabromide be not sublimed, higher numbers will be obtained. . . . It is therefore very probable that on distilling tellurium in a current of hydrogen, and the tetrabromide in a vacuum, one constituent of tellurium escapes partly, the presence of which in the last cases renders the atomic weight higher.' Brauner prepared TeBr. by fusing TeBr, with excess of Te, and subliming either in vacuo or in a current of CO,; the analyses of different specimens of TeBr, showed percentages of Br varying from 54.658 to 55.14; the percentage of Br calculated for Te = 127.32 is 55.6. Brauner concluded that 'tellurium is

not a simple substance.' This conclusion is still held by B. to be correct. In a private communication (January 1894) he says: 'I consider Te to be a mixture of two elements that cannot be separated by ordinary chemical means, not even by fractionation. It cannot, however, be shown that the at. w. of Te is about 125, for all attempts I have made in this direction have failed completely. All atomic weight determinations made by me, and others, giving values higher or lower than 127.3 are due, partly to impurities, but in most cases to some undetected source of error.'

Molecular weight of tellurium. Deville a. Troost (C. R. 56, 891) found the V.D. of Te between c. 1390° and c. 1440° to be 130; this gives the mol. w. of c. 260. As the at. w. of Te is not known with certainty, it is not possible at present to correct the value deduced for the mol. w. from the determinations of V.D. The

gascous molecule of Te is diatomic.

Reactions and Combinations .- 1. Heated in air, or oxygen, Te is burnt to TeO2-2. Heated in excess of chlorine TeCl, is produced; with bromine TeBr, is produced; with iodine the product is TeI₂—3. To and sulphur can be melted together in all proportions; it is doubtful whether definite compounds are formed or not (v. Tellurium sulphides, p. 655). Te and selenion can also be melted together in all proportions; no definite compound has been isolated .- 4. Nitric acid forms H.TeO,; according to Klein a. Morel (Bl. [2] 43, 198), cold HNO, Aq DISTIPLY DISTIPLY OF THE DESIGNATION OF THE DESIGNA hot conc. potash solution, forming a red solution that contains K.Te and K.TeO,; on addition of water Te separates (2K2TeAq + K2TeO3Aq = 3K₂OAq + 3Te).—6. Fusion with potassium nitrate produces K.TeO₄.—7. Fusion with potassium carbonate produces a mixture of K₂Te and K.TeO3.—8. Te dissolves in sulphur trioxide, forming TeSO3 (v. thio-oxide under Tellurium охибея, р. 655).

Detection and Estimation.— Free Te is readily detected by fusing with charred cream of tartar and dissolving in water, whereby a red solution is obtained that deposits Te in darkbrown flakes on standing in air. Tellurous acid and tellurites dissolve in dilute HClAq, and addition of water ppts. white H_TeO₃; SO₂ ppts. Te from solutions of tellurites in dilute HClAq or HNO₂Aq. Solutions of tellurites in acids give no pps. with water; solutions in HClAq give off Cl on boiling, being reduced to tellurites, and are then ppd. by water. For a test for Te based on the formation of red TeSO₂ by passing TeH₂ into H_SO₄Aq r. Divers a. Shimosé, C. J. 43, 329. Te is generally estimated by ppg. the element, from solution of H_TeO₂ or a tellurite, by alkali sulphite, SO₂, or grape sugar (Kastner, abstract in C. J. 29, 440; cf. Donath, abstract in C. J. 60, 242). In C. J. 59, 238, Brauner describes a method for the volumetric estimation of Te by KMnO₄Aqe

Tellurium, acids of; tellurhydric acid H₂Te (vol. ii. p. 727); tellurous acid H₂TeO₂ (this vol., p. 656); telluric acid H₂TeO₃ (this vol., p. 649). The existence of the potassium salt of HCNO is probable (v. Tellurogyanidas,

vol. ii. p. 353).

Tellurium, alloys of. The compounds of Te with metals are sometimes classed with the more definite alloys (v. Tellurides, p. 649).

Tellurium, antimonides of, v. Antimony; Combinations, No. 7, vol. i. p. 283.

Tellurium, arsenides of, v. ARSENIC; Combinations, No. 6, vol. i. p. 303.

Tellurium, bromides of. Two bromides have been isolated, Tellr₂ and Tellr₁; both are formed by the direct combination of Te and Br. The bromides can be sublimed, under reduced pressure, without change. The V.D. of neither has been determined; but, from the analogy of TeCl₂ and TeCl₄, the formulæ are probably molecular.

molecular.

Tellurium dibromide TeBr₂. Formula probably molecular, from analogy of TeCl₂. Prepared by fusing TeBr₁ with excess of powdered Te, and subliming either in racuo or in a current of dry CO₂. A blackish green crystalline mass; obtained in steel-grey needles by slow sublimation (Brauner, C. J. 55, 410). Melts c. 305°, and boils c. 343° (Carnelley, Melting- and Boiling-point Tables, 1, 21). TeBr₁ is very Poiling-point Tables, 1, 21). TeBr, is very hygroscopic; it is decomposed by water to H₂TeO₂Aq and HBrAq. Dissolves in tartaric acid solution, forming TeBr, and Te (Brauner,

Lc.).
TELLURIUM TETRABROMIDE TeBr. (Telluric bromide.) Formula probably molecular, from anatogy of TeCl. Prepared by shaking together powdered Te and Br, in the proportion Te:4Br, warning in a current of dry CO₂, and then subliming in vacuo (for details and description of apparatus, v. Brauner, C. J. 55, 396). Forms a crystalline crust, which is fiery red when hot and orange coloured when cold. S.G. $\frac{150}{40} = 4.31$ (Brauner, I.c., p. 407). Melts at c. 380°, and boils at 414°-427°, according to Carnelley a. Williams (C. J. 35, 563; 37, 125). Dissolves in a little water without change; on dilution a colourless liquid is obtained, containing HBr and H.TeO,; crystals are obtained by evaporating over H. SO, and are said by Berzelius to be TeBr, xH_O. By adding AgNO, Aq to a solution of TeBr, in tartaric acid, Brauner (C. J. 55, 398) obtained AgBr and also crystalline scales probably (C₄H₄O₅), Ag.O.TeO. 2aq; this compound is called by B. tellurium-silver tartar enectic (cf. Klein a. Morel, C. R. 100, 1140). TeBr, forms double salts with alkali bro-The salt TeBr, 2KBr (= K, TeBr,) is mides. prepared by dissolving the proper quantity of KBr in water, adding Te, running in Br, shaking till the Te is dissolved, filtering, and evaporating at 100° (Wills, C. J. 35, 711; cf. von Hauer, W. A. B. 25, 135). Dark-red, opaque, lustrous crystals; orthorhombic, a:b:c=1:1.4901:1.3658 (W., l.c.); cf. Wheeler (Am. S. [3] 45, 267), where some other salts of the form M. Telir, are described.

Tellurium, chlorides of. Two compounds are known, TeCl, and TeCl,; both have been gasified, and the formulæ of both are molecular. The chlorides are formed by the direct combination of their elements.

TELLURIUM DICHLORIDE TeCl2. Mol. w. e. 196. Powdered Te is heated in a distillation-flask in a stream of Cl until the Te is completely converted into TeCl,; Te is added equal

in weight to the original quantity used, the whole is heated for a little time, an inverted condenser being attached to the flask, and the TeCL is then distilled off at 320°-380° (Michaelis, TeCl. is then distilled off at 320°–380° (Michaelis, B. 20, 2488). TeCl, is a black, amorphous solid, melting at 175° (M., l.c.) to a black liquid; Carnelley a. Williams give m.p. as 200° (C. J. 37, 125). Boils at 327° (C. a. W., l.c.). The vapour of TcCl, is reddish, and gives a characteristic absorption-spectrum (M., l.c.). V.D. at 440°, in vapour of N. ~98°2 (M., l.c.). The sapour becomes rellowish in presence of sir or vapour becomes yellowish in presence of air or O; TeO, and TeCl, are formed, and after continued heating these react to produce TeOCl. (M., l.c.). TeCl, absorbs moisture when exposed to the air, but does not fume; on addition of much water H2TeO3 is formed; HClAq forms Te, and TeO, which remains dissolved in the acid

(M., l.c.).
TELLURIUM TETRACHLORIDE TeCl, (Telluric chloride.) Mol. w.c. 269. Powdered To is heated, in a distillation flask, in a stream of dry Cl until the solid becomes pale yellow, when it is distilled in a stream of dry CO, (Michaelis, B. 20, 1780). TeCl, is a colourless, crystalline solid, melting at 214°, and boiling without decomposition at 380° (M. Lc.; Carnelley a. Wiltiams give the m.p. as 221° [C. J. 37, 125], and the b.p. as 414° [C. J. 35, 563]). V.D. 131 at 440°, 125 at 530° (M., l.c.). The vapour of TeCl, shows no absorption-spectrum (M., B. 20, 2488). TeCl, dissolves without change in dilute HClAq. It deliquesces in the air, cold water ppts. an oxychloride, and H. TeO, is also formed; boiling water dissolves TeCl,, and H.TeO, separates on

cooling.

TeCl, combines with alkali chlorides to form salts TeCl, 2MCl = M, TeCl, ; these salts are best obtained by adding MCIAq to a slight excess of Te(1, dissolved in dilute HCIAq and crystallising (v. Wheeler, Am. S. [3] 45, 267). The salts crystallise in regular yellow octahedra, without water. Weber (P. 104, 422) described a compound TeCl₄.3AlCl₈, obtained by melting together TeCl₄ and AlCl₃. TeCl₄ absorbs NH₃, forming a greenish-yellow solid that is unchanged in air and has the composition TeCl, 2NH, (Espen-

schied, A. 113, 101).
Tellurium, fluorides of. Only one fluoride of Te has been isolated. The formula TeF, is

probably molecular, from the analogy of TeCl.

Tellutium tetrastluonide TeF. (Telluric fluoride.) Prepared by dissolving H.TeO. in HFAq, evaporating at 100° to a syrup, allowing to cool, separating the white nodules that are formed, and heating in a Pt basin (Högborn, Bl. [2] 35, 60). If carbonate or hydroxide of an alkali metal, or of Ba, is added to the solution of H.TeO, in HFAq before evaporation, double salts of the forms TeF, MF and 2TeF, MF. are obtained; these salts are decomposed by water (H., l.c.).

Tellurium, haloid compounds of. where X = Cl, Br or I; the only fluoride that has been isolated is TeF. The chlorides TeCl, and TeCl, have been gasified, and the formulae that the complex of the complex are molecular; the formulæ of the other haloid compounds are also probably molecular. An iodide containing more I than TeI4—perhaps TeI4, corresponding with SI4—may exist in the solution of H₂TeO₂ in HIAq. No compound corresponding with S₂Cl₂, Se₂Cl₂, Se₂Br₂, and Se₂I₂ has been isolated. The haloid compounds of Te are more stable towards heat than the corresponding compounds of Se or S. The haloid compounds of Te are decomposed by water, giving H₂TeO₃ and HXAq; cold water is said to ppt. an oxychloride from TeCl₄. The compounds TeX₄ combine with the haloid compounds of the alkali metals to form salts M₂TeX_a; when X=F the salts are said to be of the form MTeF_a.

Tellurium, hydride of, TeH₂ v. Hydrogen Telluride, vol. ii. p. 727.

Tellurium, iodides of. Two iodides have been isolated, TeI₂ and TeI₄; a third—perhaps TeI₄—may exist in the solution of H₂TeO₃ in HIAq. TeI₂ is formed by directly combining Te and I; TeI₄ is obtained by digesting H₂TeO₃ with HIAq.

TELUBIUM DI-IODIDE Tel. Prepared by gently warming a mixture of powered Te and excess of I; may be sublimed as a black, crystalline crust; when strongly heated I is given off. Not changed, by water, hot or cold (Berzelius, Lehrbuch, 5th edit., 3, 1139).

Tellurium tetra-iodide Tel. (Telluric todide.) Obtained by digesting powdered H₂TeO₂ with HIAq in a closed flask, whereby hard black granules are formed. Melts when heated, and gives off I. Boiling water causes decomposition, probably forming an oxyiodide. If a solu-ion of H₂TeO₂ in HIAq is evaporated over H₂SO₄ and CaO₂H₂ in vacuo, lustrous prisms are obtained that are perhaps a compound of Tel. and HI (B., l.c.). By dissolving alkali fodides in Tel. dissolved in dilute HIAq, and crystallising, black salts of the form M₂Tel. are formed in regular octahedra; the potassium salt contains 2H₂O and crystallises in monoclinic forms (Wheeler, Am. S. [3] 45, 267).

Tellurium, oxides of. Three oxides have been isolated, TeO, TeO, and TeO,. TeO is probably slightly basic; TeO, is a the anhydride of the weak acid H.TeO,, but it also shows feebly basic properties; TeO, is a very weak acidio oxide. None of the oxides has been gasified; all are known in the solid state only. An oxide of Te and S, TeSO, is also known.

Tellurium monoxide TeO. This oxide was

Tellurium monoxide TeO. This oxide was prepared in 1883 by Divers a. Shimosé (C. J. 43, 319). It is obtained by long-continued heating TeSO, to 180°-230° in vac 10 until SO, ceases to be given off, powdering the residual solid, digesting it with water containing a little Na₂CO₂, washing with hot water, then with alcohol, and drying in a steam oven. TeO is a black, amorphous solid, with a slight brown shade, showing a graphitic lustre when pressed with a hard body. It is unchanged in air, but when heated it burns to TeO₂; when strongly heated in vacuo TeO₂ and Te are formed. TeO is scarcely affected by cold KOHAq; boiling KOHAq decomposes it, giving Te. SO₃, even it boiling, scarcely acts on TeO. The oxide dissolves in hot H₂SO₂Aq; D. a. S. say that the solution deposits Te(SO₄), on cooling, but no analyses of the crystals that separate are given; Magnus (P. 10, 491) gave this formula to the product of the interaction of Te with hot conc.

H₂SO₄. Heated in HCl gas TeCl₂ is formed. TeO is slowly reduced to Te by SO₂.

Tellurium dioxide TeO, (Tellurous oxide. Tellurous anhydride.)

Occurrence.—As tellurite or tellurium ochre, in the Seven Mountains.

Formation.—1. Te is heated in the air.—2. By decomposing a boiling solution of TeCl, in HClAq by boiling water.—3. By heating H₂TeO₃.

4. By oxidising Te by HNO₂Aq, and heating the solution.—5. According to Hilger (4. 171, 211) by heating Te with H₂SO₃, SO₂ is evolved and TeO₂ separates on cooling.

and TeO, separates on cooling.

Preparation.—Powdered Te is dissolved in warm IINO, Aq. S.G. 1·25, and the solution is heated somewhat above 20°; below 8° H.TeO, separates, between 8° and 20° both TeO, and H.TeO, are formed, and the solid that forms from the solution above 20° is TeO, only (Klein a. Morel, Bl. [2] 43, 198). By allowing the solution of Te in HNO, Aq to stand for some hours, and then adding some alcohol, TeO, is obtained in crystals (Oppenheim, J. pr. 71, 267;

cf. Berzelius, P. 28, 392).

Properties. — A white, crystalline solid; melts at a red heat to a transparent, yellow liquid, which on cooling forms a white crystalline mass, giving off so much heat that the mass, giving on so much mass was solid glows feebly. TeO₂ may be sublimed in a slow stream of air. Clarke (Am. S. [3] 14, 285) gives S.G. as 5.7559 at 12.5°. As obtained from a solution of To in HNO₃Aq, TeO₂ forms quadratic octahedra; S.G. 5.65 to 5.68 at 0° (K.a. M., l.c.). As obtained by heating H₂TeO₃ till all water is removed and the residue melts, TeO₄ forms orthorhombic needles; S.G. 5.88 to 5.91 at 0° (K. a. M., l.c.). Freshly-prepared TeO, has no taste, but after a time it acquires a disagreeable metallic taste (Berzelius, P. 28, 392). It does not redden litmus paper. It is almost insoluble in water; 1 pt. dissolves in 150,000 pts. of water (K. a. M., l.c.). TeO₂ is very slightly soluble in most acids; it is more soluble in HCIAq (v. infra, Reactions, No. 3). Dissolves readily in solutions of caustic alkalis, but in alkali carbonate solutions and in ammonia only after long-continued boiling. TeO2 does not form H2TeO, by reacting with water, but as it is obtained by heating this acid it may be called tellurous anhydride.

Reactions and Combinations.—1. Reduced to Te by heating in hydrogen to the temperature whereat Te vaporises.—2. Easily reduced to Te by heating with carbon.—3. TeO₂ absorbs hydrogen chloride, giving off much heat and forming compounds TeO₂xHCl. At -10°, after saturation with HCl, the compound TeO₂.9HCl is formed; on slightly warming HCl is given off, and TeO₂.2HCl remains, and does not change when heated to 90°; on heating more strongly, TeOCl₂ is formed (Ditte, A. Ch. [5] 10, 82). Hydrogen bromide is also absorbed by TeO₂; by saturating TeO₂ with HBr at -15°, a black solid, resembling I, and having the composition TeO₂.3HBr, is formed; this compound begins to decompose at -40°, above this temperature TeO₂.2HBr is produced, which remains unchanged to c. 800°, at which temperature it decomposes to TeOBr, and H₂O (D₁, L₂). Hydrogen iodide and hydrogen fuoride are also absorbed by TeO₂ but the products have not been ex-

amined.-4. Tellurites (q. v., p. 650) are formed by dissolving TeO, in caustic alkali solutions, or by fusing TeO, with alkali carbonates.—5. A compound of TeO, with sulphuric anhydrids 2TeO_SO_—sometimes called basic tellurium sulphate—is formed by dissolving TeO, in hot H.SO, diluted with 8 to 4 times its weight of water, and evaporating; it crystallises in rhombic tablets, somewhat soluble in cold dilute rhombo tablets, somewhat soluble in contained H₂SO₄Aq (Klein, C. R. 99, 326).—6. A compound with nitric anhydride 2(4TeO₂N₁O₃),3H₂O is described by Klein a. Morel (Bl. [2] 43, 198), as obtained, in rhombic needles, by dissolving TeO, in moderately conc. HNO, Aq, and also by dissolving Te in excess of HNO, Aq, S.G. 1.15 to 1.35, and evaporating at a gentle heat. This compound—which is sometimes described as basic tellurium nitrate—is decomposed at c. 330°, giving off N oxides and decomposed at c. 550°, giving on it oxides and leaving TeO₂; with much hot water it gives a pp. of TeO₂.—7. A compound, probably TeO₂.Ag₂O.(C₄H₁O₃)...2aq, is formed by dissolving TeO₂ in HBrAq, adding tartaric acid, and ppg. by AgNO, Aq (v. Brauner, C. J. 55, 398; cf. Klein a. Morel, C. R. 100, 1140).

Telluric anhydride.) Obtained, as an orangeyellow, crystallino mass, by heating H,TeO₄ (v. Tellurio Acid, p. 649) to somewhat above 160°. If the temperature becomes too high some of the TeO, is decomposed to TeO, and O; it is advisable, therefore, to digest the residue with cold HClAq (to remove any TeO.), to wash out HClby water, and to dry at 100°. TeO, is not changed by cold, nor by boiling, water; nor is it acted on by cold HClAq, by hot or cold HNO, Aq, nor by dilute KOHAq. Very cone. boiling KOHAq slowly dissolves TeO, forming K, TeO, TeO, dissolves in boiling HClAq, Cl is slowly given off, and H₁TeO₃ is formed in the solution (v. Berzelius, P. 28, 392). Clarke (Am. S. [3] 14, 286) gives S.G. of TeO₃ as 5 0704 at 14 5°.

TELLURIUM THIO-OXIDE TeSOs. (Tellurium sulphoxide. Tellurium-sulphur trioxide.) This compound is obtained by dissolving pure Te in pure SO₃, and warming after a time to c. 30°, pouring off SO₃, and drying in vacuo (Weber, J. pr. [2] 25, 218; for description of apparatus, and details, v. Divers a. Shimosé, C. J. 43, 323). TeSO, is a red amorphous solid, melting at 30° When pure it remains unchanged, in a scaled tube, for months (D. a. S., l.c.). The colour gradually changes to brown by heating to 35°; the change is instantaneous at 90°. The product, which is a brown solid, has the composition TeSO₂ (D. a. S., l.c.). At c. 180° SO, is given off and black TeO remains (D. a. S., l.c.). TeSO₂ is not acted on by SO₃; it dissolves in 190° Ac giving a panethyst-red solution, water H.SO.Aq, giving an amethyst-red solution; water decomposes it to H₂TeO_s, TeO, Te, H₂SO_sAq, and H₂SO_sAq (D. a. S., l.c.).

TeSO, may perhaps be regarded as tellurium

sulphite.

Tellurium, oxyacids of, H₂TeO₂, v. Tellurios acid (p. 656); H₂TeO₄, v. Tellurio acid (p.

549).
Tellurium, oxybromide of, TeOBr... A paleyellow solid; obtained by heating TeO. 2HBr (v. Tellurium proxide); Reactions, No. 8, p. 654) above 300°. Melts at red heat, forming a very dark-coloured liquid, which gives off almost black vapour with partial decomposition to TeO_g and TeBr, (Ditte, A. Oh. [5] 10, 82).

Tellurium, oxychloride of, TeOCh. pared by heating TeO, 2HCl (v. TELLURIUM DI. OXIDE; Reactions, No. 8) to above 90°. Very similar to TeOCl. (Ditte, A. Ch. [5] 10, 82). Decomposed at fairly high temperature to TeO. and TeCl.

Tellurium, oxyiodide of. According to Berzelius (Lehrbuch [5th edit.] 3, 1141), a greyishbrown, heavy powder is formed by digesting Tel, with boiling water, and this powder is probably an oxylodide of Te; no analyses are given.

Tellurium, salts of. No compounds have been prepared by directly replacing the H of oxyacids by Te. According to Divers a. Shinosé (C.J.43, 319), $Te(SO_4)_2$ is formed by dissolving TeO in hot H_2SO_4Aq and cooling, but no analyses are given; Magnus (P. 10, 491) gave the formula Te(SO₂), to the product of the interaction of Te and how cone. H₂SO₃. The compounds 2TeO₂.SO₃ and 2(4TeO₂.N₂O₃). Saq are sometimes called basic tellurium sulphate and basic tellurium sulphate. rium nitrate respectively; the commound TeSO, (v. supra, Tellurium Thio-oxide) may perhaps be looked on as tellurium sulphite; and a compound, probably TeO...Ag.2. (C, II. (0))... 2aq. is called tellurium-silver tartar emetic (v. Tellurium dioxide; Reactions, Nos. 5, 6, and 7, supra).

Tellurium silver tartar emetic v. Tellurium DIOXIDE; Reactions, No. 7, supra.

Tellurium, sulphides of. Berzelius (P. 8, 411) described two sulphides, TeS₂ and TeS₃, corresponding with the oxides TeO₂ and TeO₃. According to Becker (A. 180, 257), OS₂ removes almost all the S from these supposed compounds. B. concludes that the substances described by Berzelius are not definite compounds; he thinks that compounds of Te and S are probably formed by passing H.S into TeO.Aq and TeO.Aq. As the substances obtained by Berzelius seem to have very definite properties, they are shortly described here.

TELLURIUM DISULPHIDE TeS,. A dark-brown pp. formed by passing H₂S into H₂TeO₃Aq, or into an acidified solution of an alkali tellurite; softens when heated and cools to a grey, somewhat lustrous mass; gives off S when strongly heated. TeS, reacts as an acidic sulphide, forming compounds &MS.TeS., where M = (NH.), Cd, Li₂, Fe, Mg, Pb, K₂, Na₂, Zn, &c. The thiotellusites of the alkali metals are best obtained by saturating aqueous solutions of the tellurites with H2S, and crystallising in vacuo; the thiotellurites of alkaline earth metals are formed by boiling the sulphides of these metals with TeS₂ and water; the thiotellurites of the heavy metals are obtained by μρn. from solu-

Tellurium trisulphide TeS. A blackish grey, lustrous solid; formed by saturating H.TeO.Aq with H.S. and allowing to stand for some time in a closed vessel in a warm place. Thiotellurates of the alkali metals, xM.S.TeS. anotecurates of the alkali metals, xM,N.TeS,, are formed by saturating M,TeO,Aq with H,S (v. Oppenheim, J. pr. 71, 267).
Tellurium, sulphoxide of, v. Tellurium Thio-

OXIDE, supra.

Tollurium, thio-oxide of, v. supra,

Tellurium, thio-salts of, v. Tellurium disul-PHIDE, p. 655; and TELLURIUM TRISULPHIDE, p. M. M. P. M.

TELEUROCYANIDES v. vol. ii. p. 853. TELLUROUS ACID H.,TeO.

Formation. -1. By dissolving Te in HNO.Aq. S.G. 1.25, and at once ppg. by water; if the solution is left for some time before adding water the pp. is TeO, -2. By decomposing TeCl, by

Preparation.—TcO₂ is fused with an equal weight of K₂CO₃ or Na₂CO₃ as long as CO₂ is given off; the tellurite thus formed is dissolved in water, and HNO, Aq is added until the liquid has a very distinctly acid reaction; the flocculent pp. thus produced is allowed to remain in contact with the liquid for some hours, and is then thoroughly shaken up with the liquid, a little HNO, Aq being added if the acid reaction disappears during this process; the pp. is then washed with ice-cold water, and dried at the ordinary temperature (Berzeliu, P. 28, 392; cf. Oppenheim, J. pr. 71, 267). The sciution of the alkali tellurite in HNO Aq may be decomposed by adding water, but this must be done at once, as after standing water ppts. TeO2.

Properties and Reactions .- A white, light, amorphous solid, with a bitter, metallic taste. Reddens litmus paper. Dissolves slightly in cold water; when the aqueous solution is heated to c. 40° TeO₂ separates. When slightly heated gives TeO₂ and H₂O. H₂TeO₃ disolves in many acids; from the solution in HClAq, water or alkalis Pots. H.TeO.; the solution in HNO Aq gives a pp. of TeO₂ on addition of water after standing for some time. From the solution in H₂SO₄Aq and HNO₃Aq the compounds 2TeO₂SO₂ and 2(4TeO₂N₂O₃), 3aq have been obtained (v. Tellurium Dioxide; Reactions, No. 5 and 6, p. 655). H.TeO, forms tellurites (q. v., p. 650). Thomsen (Th. 2, 278) gives $[Te,O^2,H^2O] = 77,180$. M. M. P. M.

TELLURIUM, Organic Compounds of.

Methyl telluride Me. Po. (82°). Formed by distilling K. To with Ba(SO, Me). (Wöhler a. Dean, A. 93, 233; Heeren, Dissertation, Göttingen, 1861). Pale-yellow, mobile, heavy oil, with persistent alliaccous smell. Oxidised by HNO, to Me, ToOIINO, crystallising in prisms .-Me.TeHOAc. Transparent cubes, v. sol. water. which crystallises in long prisms [97.5°].—
Me,TeBr, [89°]. Prisms.—(Me,Te),H,CO, Difficult to crystallise.—Formate Me,TeCH,O. Deliquescent needles.—Me, Tel₂. Formed by heating Te with McI at 80° (Demarcay, Bl. [2] 40, 100).—(Me, Te), H, C, O, —Me, TeO. Got from Me, TeCl₂ and Ag, O. Deliquescent crystalline mass, alkaline to litmus.—Me, TeOCl₂. Got from the chloride and NH, Aq. Short prisms (from alcohol). — (Me₂Te)₂OBr₂. — (Me₂Te)₂H₂SO₄. Cubes, v. sol. water, insol. alcohol.

Methyl-iodide Me Tel. Crystalline, sl. sol, water. Converted by moist Ag₄O into an alkaline base which yields (Me, TeCl), PtCl,.

Ethyl telluride v. vol. ii. p. 519.

TEMPLIN OIL. An essential oil obtained from fir cones (Flückiger, J. 1855, 642; Berthelot, J. Ph. [8] 29, 38). Colourless, becoming greenish-yellow in air. Boils at 155°–177°. S.G. 18 Yields on rectification a laworotatory

terpene (172°) S.G. 4 ·856. HNO, (1 vol.) and alin the series (172) S.O. 2. 300. INO₃ (§ Vol.) and alcohol ($\frac{1}{3}$ vol.) yield terpin hydrate $C_{10}H_{20}O_{2}$ aq [118°] (250°) S. 9 at 100°. Alcohol and HCl yield crystalline $C_{10}H_{18}$ HCl and $C_{10}H_{18}$ 2HCl

[559].
TERACONIC ACID C.H., O. i.e.
CMe.: C(CO.H). CH., CO.H. Propylidene-succinic [163°]. Formed in small quantity by distilling the isomeric terebic acid (Geisler, A. 208, 50). Na and NaOEt convert terebic ether into sodium ethyl teraconate (W. Roser, B. 15, 293). Formed also by treatment of the ether CO.Et.CBrPr.CH. CO.Et with alcoholic potash (Schleicher, A. 267, 130). Crystals, sol. alcohol and ether, v. sol. cold water. Above 163° it yields H.O and an anhydride. Conc. HBrAq at 0° forms terebic acid.

Salts.—BaA".—CaA". Pp., v. sl. sol. water. Ag, A". Needles, m. sol. water. Mono-ethyl ether ΕtΠΑ". Oil. Decom-

poses Na₂CO₃, forming crystalline NaEtA", a solution of which gives with AgNO₃ a pp. of the unstable AgEtA".

Di-ethyl ether Et.A". (255 i.V.). Oil. TERACRYLIC ACID C,H,2O₂. (218° i.V.). product of the distillation of terpenylic acid (Fittig a. Krafft, B. 10, 521, 1659, 1740; A. 208, 79; Amthor, J. pr. [2] 42, 389). Liquid, smelling like valerie acid, sl. sol. and lighter than water. Yields acctic acid on fusion with potash. Fuming HBr forms C,H,BrO2, which gradually splits up into HBr and heptolactone C,H12O2. CaA'₂5aq. Prisms or needles.—AgA': needles. Ethyl ether EtA'. (191°). Fruity oil.

TERBIUM. Tr. At. w. not determined with certainty; probably c. 162 (v. infra).

The examination of gadolinite, a rare Swedish mineral, by Mosander, Cleve, and others made probable the existence therein of at least seven earths, to one of which the name terbia was given (v. Erbium, vol. ii. p. 456, where the history of these earths is stated more fully, with references to original memoirs). It is still very doubtful whether the substance called terbia is a homogeneous body or a mixture of more than one compound (cf. METALS, RABE, vol. iii. p. 242). Delafontaine (A. Ch. [5] 14, 238) prepared an orange-yellow, earthy compound, which he regarded as pure terbia, from samarskite, by a long process of fractional ppn., first by K₂SO₄Aq, ther by oxalic acid, and finally by formic acid (cf. Marignac, A. Ch. [5] 14, 247; Cleve, Bl. [2] 31, 197).

Terbia Tr₂O₂ is described as an orange-yellow

amorphous solid; when heated in H for some time it becomes white. Tr_iO_3 dissolves in acids, forming salts of the type Tr_iX_3 , where $X = SO_1$, CO_2 , $2NO_3$, &c. The emission spectrum of terbia has been mapped by Roscoe a. Schuster (C. J. 41, 283). The at. w. of Tr—the supposed element has not been isolated—was determined by Delafontaine to be 113.5; Marignae found the value 148.5; Lecoq de Boisbaudran found 163.1, 161.4, and by later work 159.5 (C. R. 102, 395;

111, 474). M. M. P. M. TERÉBENE v. Terpènes.

TEREBENTHENE v. TERPENES DITEREBENTHYL C. H.s. V.D. 4.6. (345°). S.G. 12 '9688. $[a]_D = 59^{\circ}$. A product of distillation of colophony (Renard, C. R. 105, 865; 106, 856). Oil, resinified by air. KMnO₄ oxidises it

to propionic, acetic, and formic acids and CO... to propionic, acetic, and formic acids and CO₂. Cold fuming HNO₂ forms C₂₀H₂₇(NO₂), a yellow powder, sol. alcohol and ether. Br in CS₂ at -10° forms C₂₀H₂₈P₁₇, which on heating yields diterebenthylene C₂₂H₂₈ (347°) S.G. 12° 9821, whence Br forms C₂₀H₂₁Br₁. HNO₂ produces C₂₀H₂₁(NO₂), and HSO₄ forms C₂₀H₂₁SO₄H, all amorphous solids. Reminion water since C_{x2}H_{x2}(NO_x)_x and H_xSO_x forms U_{x2}n_x; SO_xn, an amorphous solids. Bromine-water gives rise to C_{x2}H_xB_x, a brown, amorphous solid. Gaseous HCl passed into the ethereal solution forms C_{x2}H_{x2}HCl. H_xSO_x yields C_{x2}H_{x2}SO_xH, which is sol. water, alcohol, and ether, forming fluorescent solutions. Diterebenthyl passed fluorescent solutions. Diterebenthyl passed through a red-hot tube forms H, C,H,, C,H, pentane, hexane, hexylene, hexinene, heptinene, cymens, and other hydrocarbons.

TEREBENTILIC ACID C,H,OO, [90°]. (250°).

Got by passing the vapour of the hydrate of oil of turpentine C_{in}H_{in}2H_iO over soda-lime at 400° (Personne, A. 100, 253; cf. Hempel, A. 180, 86). Crystalline powder, sol. hot water, v. sol. alcohol and ether. May be sublimed .- AgA'. Crystalline.

TEREBENTIC ACID C₉H₁₄O₅. Got by discesting oil of turpentine with oxide of lead (Weppen, A. 41, 294). Crystals (from alcohol). TEREBIC ACID C,H₁₀O₄ i.e.

 $CMe_2 < CH(CO_2H) > CH_2$. Mol. w. 158. [176°]. H.C.v. 766, 642 (Ossipoff, C. R. 108, 812). S. (ether) 2.856 at 35° (Amthor, J. pr. [2] 42, 385). Formed by the action of nitric acid on oil of turpentine (Bromeis, A. 37, 297; Rabourdin, J. Ph. [3] 6, 185; Cailliot, A. Ch. [3] 21, 27; Svanberg a. Eckmann, J. pr. 66, 220; Mielck, A. 180, 47; Bredt, A. 208, 37; Erdmann, A. 228, 179). Formed also by oxidising pinol (Wallach, A. 253, 256; 259, 317). Terebic acid is perhaps identical with oxyhexic acid (Gorboff, J. R. 1887, 605). Monoclinic crystals (from alcohol), sl. sol. cold, v. sol. hot water. V. sol. alcohol and ether. Not attacked by furning HNO₂. Splice up by water at 150° into CO₂ and pyroterebic acid. On boiling with H₂SO₄ (2 pts.) and water (1 pt.) it is converted into the lactone of oxyisohexoic acid CMe₂ CH₂ CH₂, CO₂ being evolved. On distillation it yields pyroterebic (hexenoic) acid, oxy-isohexoic lactone, and a little teraconic acid. On heating for 15 hours at 160° with excess of a saturated solution of baryta it is converted into acctone and succinic acid (Frost, A. 226, 363). Fuming HIAq yields CH.Pr.CH.2CO.H. Alkalis form salts of diaterebic acid, of which terebic acid is the lactone.

Salts.—NH₄A': very soluble prisms.—
KA';aq.—NaA';aq.—BaA';2q: amorphous.—
AgA'. Prisms, v. sol. water.

Ethyl ether Eth'. (274° i.V.). S.G.

1. 1.111. Formed from terebic acid, alcohol, and HCl. Dilute NaOH dissolves it, forming monoethyl diaterebate; on cautious acidification the ether separates again, but only after warming (Ekmann). Sodium dissolves in its ethereal (F.Kinani). Southin dissertes in 100 emilies solution, giving off hydrogen and forming the sodium salt of acid ether of teraconic acid (q, v). Alcoholic NaOEt acts in the same way, excess torming a white pp. of disodic teraconate.

Diaterebic acid

CMe,(OH).CH(CO,H).CH,.CO,H. The salt BaA" 3aq is formed by boiling terebic acid with excess of baryta-water. It crystallises from Vot. IV.

alcohol, but on acidification at once yields the lactone, terebic acid. AgNO, added to a solu-

lactone, terebic soid. AgNO, added to a solu-tion of the Ba salt ppts. Ag, A".—CaA" Saq.— CaA".—PbA" 3aq.—Pb, A", (OH), aq.

Ethyl ether Et, A". Formed from Ag, A" and Etl. Oil. Converted by acetyl chloride into CMc_(OAc).CH(CO_Et).CH_.CO_Et, an unstable

β-Bromo-terebic acid C,H,BrO, i.e.

CMo₂ CBr(CO₂H) CH₂. [151°]. Formed by adding Br (1 mol.) to powdered teraconic acid (1 mol.) covered with water (Frost, A. 226, 363). Large crystals, m. sol. CS., v. sl. sol. chloroform and benzene. Decomposed by boiling with water into HBr and terebilic acid C.H.O. Reduced by sodium-amalgam to terebic acid.

References .- CHLOROand OXY-TEREBIO

TEREBILENIC ACID C,H,O, i.e.

 $CMe_2 < C(CO_H) > CH$ (?) [169]. Formed by herting a-chlord-terebic acid at 200° (Roser, B. 15, 296; A. 220, 261) and by evaporating B-chloro-terebio acid with water (Frost, A. 226, 370). Small prisms or needles (from water), v. sol. alcohol and other. Crystallises from alcohol or cone. HBrAq in trimetric forms; a:b:c=809:1: 858. May be sublimed. Excess of KOH forms the diaterebilenate K,C,H,O,, but this splits up on warming with water into KOH and potassium terebilenate. Does not combine with Bror HBr. Sodium-amalgam reduces it to terebio acid. -- CaA'₂.--AgA'. Prisms.

Reference.-- Chloro-threbulenic acid.

TERECHRYSIC ACID C. 11.03. A product of the action of HNO₄ (S.G. 1-2) on turpentine (Cailliot, A. 64, 376). Orange-red crystals, v. c. sol. water, alcohol, and ether. —PbA": crystals.

TERELACTONE C, II, O, i.e. C, II, O. [12°]. (210° i.V.). Formed by the action of boiling water on di-bromo-isohexoic acid derived from pyroterebic acid and Br (Geisler, A. 208, 47). Mobile liquid, sol. water. Douing out you converts it into amorphous Ba(C_qH_qO_q), which is sol. water and deposits BaCO_q on boiling.

TEREPHTHALIC ACID O_qH_qO_q i.e.

C_sH_s(CO₂H)₂. p-Phthalic acid. Mol. w. 166. H.C.p. 770,900. H.C.v. 771,200. H.F. 188,100

(Stohmann, J. pr. [2] 40, 139).

Formation.—1. By the action of HNO, on oil of turpentine (Cailliot, A. Ch. [3] 21, 28; De la Rue a. Hugo Müller, A. 121, 86; Schreder, B. 7, 704; cf. W. C. Williams, B. 6, 1094).—2. By the oxidising action of chremic acid mixture on p-xylene (Beilstein, A. 133, 32; 137, 301), p-xylene (Rentstein, A. 133, 32; 137, 301), cuminic acid, cuminic aldehyde, cymene (Hofmann, A. 97, 197), p-toluic acid (Beilstein a. Yssel, A. 137, 308), di-ethyl-benzene, and amyltoluene (Fittig, A. 141, 167).—3. By the action of boiling dilute HNO, on cymene and on terpenes (Schwanert, A. 132, 257; Homeyer, Ar. Ph. [3] 5, 326).—4. By oxidation of o-ethyltolura Picarcel B. toluene by aqueous KMnO₄ (Claus a. Pieszcek, B. 19, 3083).—5. By fusing potassium p-sulphobenzoate with sodium formate [Remsen, B. 5, 379]. - 6. From its nitrile, which is obtained by distilling K.FeCy, with potassium benzene p-disulphonate (Garrick, Z. 1869, 551), p-chlorobenzene sulphonate (Nölting, B. 8, 1113), or p-

bromo-benzene sulphonate (Irelan, Z. 1869, 164; Barth a. Senhofer, A. 174, 242; Limpricht, A. 180, 88).—7. The semi-nitrile is also formed by the action of a hot solution of cuprous potassium cyanide upon p-diazobenzoic acid (Sandmeyer, B. 18, 1497). - 8. By heating p-di-bromo-benzene with chloroformic ether and 1 p.c. sodium-amalgam at 110° and saponifying the product (Bonz, B. 18, 2305).—9. By the action of 5 p.c. KMnO₄ on an oil (258° 268°) which remains as a residue in the manufacture of aniline and toluidine (Hell a. Rockenbach, B. 22, 505).

Preparation .- 1. Br (2 mols.) is added to boiling p-xylene (100 g.), and the resulting C₄H₄(CH₂Br)₂ decomposed by alcoholic KOAc on the water bath. After evaporating the alcohol the C_rH_{*}(OAc)₂ is extracted with ether, and oxidised by adding 4.5 litres of 10 p.c. KMnO₄ to its solution in water (1 litre) and NaOH (500 g. of S.G. 1.22). Finally more KMnO, is added till the solution remains violet, the solution kept at 100° for 3 hours, filtered, and ppd. by HCl (Baeyer, A. 245, 139) .- 2. By oxidising p-xylene with chromic acid mixture (Beilstein, A. 133, 41). 3. From p-toluidine by Sandmeyer's reaction, the resulting p-toluic acid being oxidised by

KMnO₄ (Baeyer a. Herb, A. 258, 1).

Properties.—White crystalline powder, nearly insol. water, alcohol, ether, chloroform, and HOAc. Sublimes without previous fusion. Does not yield an anilide on boiling with aniline (Michael a. Palmer, B. 19, 1376). It is ppd. from its salts by pthalic &cid. Yields benzene when distilled with slaked lime. Reduced by sodium-annalgam in a current of CO_2 to the $\Delta^{2\ell}$ or (1,4) dihydride. If CO_2 be not used the Δ^{1,t} or (1,4) dihydride. If CO₂ be not used the product is the Δ^{1,t} or (3,6)- dihydride, which is also get by boiling the (1,4)-dihydride with NaOHAq (Baeyer, A. 269, 153; cf. Mohs, Z. [2] 3, 68). The (1,4)-dihydride gives benzoic acid on oxidation by MnO₂ and dilute H₂SO₃, while the (3,6)-dihydride forms terephthalic acid (Baeyer, A. 269, 182). By heating its alkaline solution with sodium, suglement terephthalic acid solution with sodium-amalgam terephthalic acid is reduced to a tetrahydride, and this is further reduced by HIAq at 240° to a hexahydride (Baeyer, B. 19, 1805).

(Baeyer, B. 19, 180a).

Isomyl ether (C,H₁₁),A". Pearly scales. Phonyl ether !h₂A". [194°] (Baeyer, A. 258, 44). Formed from the chloride and phenol. Leaflets.

Chloride C.H.(COCI).. [78°]. (259°).

Amio acid C.H.(CONH.).CO.H. [214°].

Formed from p-diazo-benzoic acid by Sandmeyer's reaction (Sandmeyer, B. 18, 1498).

Minute plates (from water), m. sol. cold water.

Amide C₆H₄(CONH₂)₂. Formed from the chloride and NH₃Aq. Amorphous.

Nitrile C₆H₄(CN)₂. [220°] (Luckenbach, B. 17, 1428). Formed from the amide and P.O. Got also by distilling calcium brono-benzene p-sulphonate with K,FeCy. Conc. HIAq forms C,H,(CI_NH₂), (Biltz, B. 25, 2543). Γ cistrans $\Delta^{3.5}$ or (1,4)- Dihydride

CO₂H.CH<CH:CH>CH.CO₂H. S. 3 in the

cold. H.F. 182,600 (Stohmann, J. pr. [2] 43, 538). Formed by reducing terephthalic acid in a current of CO₂ by sodium-amalgam (Baeyer, $A.\,251,\,257;\,269,\,153$). Monoclinic prisms (from EtOAc); $a:b:c=\cdot982:1:1\cdot019$; $\beta=78^{\circ}$ 2'. M. sol. cther. Not attacked by sodium-amalgam in the cold. Unites with bromine (4 atoms). Transformed into the $\Delta^{1.5}$ isomeride by boiling with Not attacked by sodium-amalgam in the water, and into the $\Delta^{1.4}$ acid by boiling with NaOHAq. Alkaline KMnO, re-oxidises the acid to terephthalic acid. A warm solution of the acid readily reduces AgNO₂. On warming with aqueous cupric acetate it gives off CO2 and forms a white pp. which, on adding HOAc and warming, yields Cu₂O₂ the liquid then containing benzoic acid. The (3,6), (3,4), and (2,8) isomerides do not reduce AgNO₂ and cuprio acctate. The Ba salt crystallises in plates, and is v. sol. water.

Methylether Me. A". [77°]. Yields a diand a tetra-bromide. Br in CHCl, forms a dibromide [170°] and a tetrabromide [98°].

Di-phenyl ether Ph₂A". [146°]. Formed from the chloride and phenol at 100°. Small crystals, sl. sol. alcohol, ether, and ligroin.

 Γ cis $\Delta^{2,5}$ or (1,4)- Dihydride

CO_H.CH<CH:CH>C(CO_H)H. Extracted by

ether from the mother-liquor from which the preceding isomeride has separated. Closely resembles its cistrans isomeride, but the cis acid and its salts are the more soluble.

 $\Delta^{1,5}$ or (3,4)- Dihydride

 $CO_2H.CH < \stackrel{CH}{<} \stackrel{CH}{<} \stackrel{CH}{>} C.CO_2H.$ S. 042 in the

cold. H.F. 185,300. Formed by boiling the (1,4)-dihydride with water, and obtained, therefore, by reducing terephthalic acid with sodium-amalgam (Baeyer, A. 245, 142; 251, 257; 269, 148). Converted into the (3,6)- acid by NaOHAq. Sodium-amalgam in the cold reduces it to the Δ' tetrahydride.-BaA" 4aq. Trimetric orystals; a:b:c = :319:1: 352 (Baeyer a. Herb, A. 258, 22).

Methylether Me, A". [40°].

Δ1,4 or (3,6). Dihydride

CO₂H.C CH₂CH₂C.CO₂H. S. 0059 in the

cold. H.F. 191,900. Formed by reduction of terephthalic acid in a kaline solution by sodium. amalgam (Baeyer, A. 245, 142). Got also by boiling the (1,4)-dihydride with NaOHAq. Slender needles (from water), almost insol. ether. Much resembles terephthalic acid. On sublimation it is partially converted into terephthalic

acid. Immediately oxidised by KMnO4. Forms CH(CO,H) CH, .CHBr CH.CO,H by uniting with HBr. Sodium-amalgam in the cold reduces it to a slight extent, forming the two isomeric Δ² tetrahydrides.—BaA"4aq. Crystals,

resembling its $\Delta^{1,5}$ and $\Delta^{1,8}$ isomerides. Mono-methyl ether MeHA". [225°]. Got from Me,A" and alcoholic potash. Needles

(from hot-water).

Di-methyl ether Me.A". [130°]. H.F. 172,700. Formed from the dihydride by-successive treatment with PCl_s (2 mols.) and MeOH. Monoclinic plates (from EtOAc); a:bc=1·52:1:2·79; β =c. 74°. Sl. sol. water, m. sel. hot alcohol, v. e. sol. ether. Br in CHCl, yields a dibromide C, H, Br₂(CO,Me)₂ [90°] and a tetrabromide [150°]. Excess of Br yields CO₂Mo.C_eH_eBr

CO [188°]. HBr forms

C₂H_eBr₂(CO₂H)₂ which yields C_eH_eBr₂(CO₂Me)₂ [166°].

Di-phenyl ether Ph.A". [191°]. Formed by treating the chloride with phenol (Baeyer a. Herb, A. 258, 31). Small scales (from hot

MeOH), sl. sol. ether.

Δ ^{1,3} or (5,6). Dihydride CO₂H.C ≪ CH₂CH₂CH₂ ⊗ C.CO₂H. S. 0053 in the cold. Formed by the action of alcoholic potash on the dibromide of the \(\Delta^2 \) tetrahydride and on the tetrahydride of di-bromo-terephthalic acid got by bromination of the hexahydride. Unites with hydrogen bromide (2 mols.) forming CO_H.CH<CH_CHBr.CHBr>CH.CO_H. Easily reduced by Zn and HOAc and by sodium-amalgam to the two A2 tetrahydrides. Boiling water converts it into the (3,4)- isomeride. Boiling NaOIIAq forms the (3,6)- isomeride.—BaA" 4aq. Needles (from hot water).

Methyl ether Me.A".

Methyl ether Me.A". [85] Monoclinic plates; a.br. = 2'211:1:3'591; \$\beta = 87' 13'. Slowly converted by HBr into (2,3)-di-bromo-terephthalic acid hexahydride, which is reduced by since the state of t zinc-dust and acetic acid to the \(\Delta^2 \) tetrahydride of terephthalic acid. Yields a dibromide [61°].

Di-phenyl ether Ph.A". [175°]. Large needles (from MeOH), sl. sol. cold alcohol.

Δ' or (3,4,5,6). Totrahydride.

CH(CO_H) < CH_CH_SCLO_H. [above 300°]. S. 102 at 16°; 83 at 100°. H.F. 214,200 (Stohmann, J. pr. [2] 43, 5). Formed by boiling a solution of terephthalic acid (1 pt.) in NaOHAq for twenty hours with gradual addition of 4 p.c. sodium-amalgam (100 pts.) (Baeyer, B. 19, 1805; A. 245, 160; 258, 32). Prisms, more sol. water than terephthalic acid or its dihydrides. Combines with HBr and with Br (1 mol.). Immediately reduces alkaline KMnO, yielding oxalic acid.—BaA" 3 aq. M. sol. cold water. Reduced by HIAq at 240° to the hexahydride.—Ag.A". Amorphous.

Methylether Me.A". [39°]. H.F. 196,200. Plates. Its ethercal solution shows blue fluor-NaOEt. HBr gives C.H.Br(CO.H), whence Ma.A." [95°]. Bromine forms C.H.Br₂(CO₂Me), [81°].

Di-phenyl-sther Ph.A". [145°]. Formed

from the acid by successive treatment with PCl, and phenol. Monoclinic crystals; a:b:c=2.824:1:2.470, m. sol. cold alcohol and other.

Γ cistrans Δ2 or (1,4,5,6)- Tetrahydride CH(CO₂H) CH₂CH₂OH.CO₂H. [c. 220°]. S. 17. Formed, by reducing \$\Delta^{1,5}\$ dihydride and also the dibromide of the \$\Delta^{1,5}\$ dihydride. Oxidised by KMnO, in the cold to succinic acid and a soluble acid [150]. Alkaline K,FeCy, gives terephthalic acid. Yields three dibromides terephthalic acid. Yields three c CH(CO₂H) < CH₂ .CH₂ .CH₃ > CH.CO₂H. [51°], and [94°]. The Ba and Cd salts are more sol, water than those of the Δ^1 isomeride.

Methyl ether Mo.A". [0. 30].

Amide. Dimetric needles; a:c = 1:2:151.

Diphenyl ether PhA". Formed, in two modifications [107°] and [c. 190°] by the successive action of PCl, and phenol (Baeyer a. Herb, A. 258, 39). The modification [c. 190°] probably is a mixture containing the Δ^1 isomeride.

Dibenzybether (C,H,),A". [48°]. From

Ag, A" and benzyl chloride.

 Γ cis Δ^2 or (1,4,5,6)- Tetrahydride. [150°-155°]. S. 2.7 in the cold. Formed, together with the cistrans isomeride, by reducing the A1.4 dihydride by sodium-amalgam in the cold. The Ba, Cd, and Ag salts are amorphous. This acid and the cistrans isomeride are converted into the A1 isomeride by boiling with NaOHAq. l' cistrans Hexahydride

CO.H.CH. CH., CH., CH., CO.H. Funaroid or stable modification. [300°]. S. 086 at 16°; 13 at 100°. H.F. 236,500 (Stohmann, J. pr. [2] 43, 7). Formed by heating the tetrahydride with HIAq for 6 hours at about 240' (Baeyer, B. 19, 1806; 245, 170; 251, 257). Formed also by heating ethyl butane tetracarboxylate with NaOEt and ethylene bromide at 100°; the product being hydrolysed and heated at 220° till evolution of CO₂ ceases (Mackenzie a. Perkin, jun., C. J. 61, 174). Prepared by reducing the hexahydride of bromo-terephthalic acid zinc-dust and HOAc. Small prisms, sol. hot water. May be sublimed. Not oxidised by cold alkaline KMnO. Br (2 mols. at 100°) forms $C_aH_0Br(CO_2H)_2$ [71°], and a maleic isomeride Treatment with PCl, followed by Br at [203]. Treatment with Pol_a tollowed by B as 150° forms C_aH_aBr_a(CO_aH_b)₂ in a funaroid modification which yields Me_AA" [150°] and a maleic modification which yields Me_aA" [68°] and an anilide [200°]. The K and Ba salts are v. sol.

anima (2007). The K and Da sates are V. sol. water; the Ca salt is sl. sol. water.

Methyl ether Me.A". [71°]. S. .5 at 100°. H.F. 218,100. Exhibits no fluorescence. S. .5 at. Volatile with steam.

Diphenyl ether Ph.A". [151°]. Needles. r cis Hexahydride

CO₂H.CH CH₂CH₂CH₂C(CO₂H)II. Maleic or [162°]. H.F. 287,400. labile modification. Formed by reducing the very soluble hexa-hydride of bromo-terephthalic acid with zincdust and HOAc. Plates (from water), v. sol. alcohol and ether. Changes on heating with HClAq at 180° into its isomeride. Its Ba salt and methyl ether do not crystallise.

OXY- TEREPHTHALIC ACID.

TEREPRIHALIC ALDEHYDE

TEREPHTHALIC ALDEHYDE
C₄H₄(CH₀)₂[1:4]. [116°]. (247°). S. 1·7 at
100°. Formed by boiling C₂H₄(CH₂Cl)₂ or
C₄H₄(CH₂Br)₂ (1 pt.) with lead nitrate (1 pt.) and
water (20 pts.) (Grimaux, C. R. 83, 825°; Lōw,
A. 231, 363). Formed also by the action of
fuming HNO₂ on disweromo-pt-xylene (Lōw, B. 18, 2072), and by boiling C_cH₁(CHCl₂), with water (Colson a. Gautier, Bl. [2] 45, 6, 508). Obtained from CH₂(OH).C_cH₁.CH₂OEt by successive treatment with PCl₂ and water (Colson, Bl. [2] 42, 152).
